ORIGINAL LECTURES.

PHILADELPHIA COUNTY MEDICAL SOCIETY LECTURES.

ON THE PHYSICAL EXPLORATION OF THE LUNGS BY MEANS OF AUSCULTATION AND PERCUSSION.

A course of three lectures delivered by invitation before the Philadelphia County Medical Society.

BY AUSTIN FLINT, M.D.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

LECTURE I.

TRUE MODE OF STUDY AND ITS REQUIREMENTS AS REGARDS AUSCULTATION AND PERCUSSION. THE SIGNS OBTAINED BY PERCUSSION.

Delivered November 25, 1882.

MR. PRESIDENT AND MEMBERS OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY: The invitation to give a few lectures on some subject pertaining to practical medicine was accepted by me with a full appreciation of the high compliment and the responsibility therein involved. I cannot adequately express the gratification which I shall feel if, at the close of the lectures, I may be able to persuade myself that any expectations on your part, beyond the gratification of a complimentary disposition, have been measurably fulfilled. The subject selected, with the approval of the Committee on Lectures, is one to which for many years I have given much attention as a clinical student, and a clinical teacher. It may seem to be a hackneyed subject, but I hope to succeed in showing that it is one which at the present time claims attentive consideration with reference to a further increase, and a more general diffusion of the usefulness of its practical applications in the diagnosis of diseases.

INTRODUCTORY REMARKS.

The discovery of auscultation by Laennec in 1816, led to the resurrection of percussion as a method of physical exploration, a method brought into existence by Auenbrugger, but which the publication in Latin, in 1761, of the *inventum novum*, failed to keep alive, and which Corvisart, by his translation of Auenbrugger's treatise into the French language with abundant commentaries, published in 1808, had vainly attempted to reanimate. Restored to life by Laennec, percussion has since been hand in hand with auscultation. Each of these two methods has given invaluable aid to the other. They cannot with propriety be disjoined in practice, and they are necessarily associated in treating of the diagnosis of diseases. It would be of little use to discuss the relative advantages of the two methods. Doubtless, were we to be deprived of one of them, we could better afford to lose percussion than auscultation, but the advantages of either would be greatly diminished by the loss of the other. A more useful point of inquiry is, What progress has been made in our knowledge of physical exploration by the two methods conjointly since the time of Laennec? In answer to this inquiry, I have no intention to review in detail the labors of those who have cultivated this field in practical medicine since Laennec's day. They occupy a considerable space in the medical literature of the last half century. I shall offer some general statements, by way of introduction to the lectures, to which your attention is invited. The facts in auscultation which Laennec discovered constitute much stronger evidence of his genius than the discovery of the method. The latter, as he relates, was accidental. It is a marvel that he ascertained so much of what is known of auscultatory phenomena at the present time. The medical student of to-day may read his treatise with advantage on account of the accuracy of the observations, as well as affording a model of truth-loving candor and unaffected simplicity. It would have been strange indeed, if, in the interpretation of his observations, he had not fallen into some errors, and had he not failed to recognize all the directions in which the subject affords scope for clinical study. Of the many works which have appeared since the publication of Laennec's treatise, I will mention here but one, namely, the work of Skoda, published in 1839. This work passed through several editions, and was translated into the French and the English language. A considerable portion of the work is devoted to a refutation of Laennec's physical explanations of auscultatory phenomena. The tone of criticism is dogmatical, and it might perhaps be said to be arrogant. The author substitutes his own theories for the explanations given by Laennec, classifies differently the physical signs obtained by auscultation and percussion, and designates their distinctive characters by different terms. I shall refer to this work repeatedly in the course of my lectures, and oftener with dissent than with concurrence. The work has had a controlling effect upon the views of German medical writers up to the present moment, and, also, not an inconsiderable influence on the views of writers in other countries. I do not hesitate in expressing my belief that thereby auscultation and percussion have been injured as regards progress and the diffusion of knowledge in these branches of practical medicine.

Much as has been acquired by means of these two methods of exploration within the last fifty years, the place which they now hold in medical practice is not, as it seems to me, proportionate to the labor given to them, and the space which they now occupy in medical literature. Many practitioners make but little use of them. They are considered as constituting a specialty. There is lack of unanimity among those who bestow upon them special consideration, or regard the number of physical signs, the characters by which they are designated, and the significance which respectively belongs to them. The want of unanimity in the names used to designate different signs was so apparent in the discussion by the members of the Section in Medicine at the meeting of the International Medical Congress in 1881, that a committee was appointed to report an uniform nomenclature, at the next congress. This committee is composed of representatives from England, France, Germany, and the United States. It remains to be seen what they may accomplish.[1]

Writers are apt to enter largely into theoretic discussions relating to the mechanism of physical signs, discussions which are not essential, often unprofitable, and not infrequently leading to errors of observation.

[1] The members of this committee are as follows: Prof. Austin Flint, of New York, Chairman; Prof. Ewald, of Berlin; Prof. D'Espine, of Geneva; Dr. Powell and Dr. Mahommed, of London.

By some writers signs have been needlessly multiplied, and the subject has been rendered apparently mysterious and abstruse by over-refinements. These are obstacles which have retarded progress in the knowledge of auscultation and percussion, and limited their practical use by medical practitioners.

THE TRUE MODE OF STUDY AND ITS REQUIREMENTS AS REGARDS AUSCULTATION AND PERCUSSION.

The true mode of study has been overlooked. By adopting and keeping steadily in view the requirements of the true mode of study, as I firmly believe, the obstacles just referred to will be avoided, our knowledge of physical signs will have a degree of precision which will make them far more available in diagnosis than hitherto, and the practice of auscultation and percussion will have a simplicity which should place its advantages in the hands of every intelligent, well-educated practitioner of medicine. What are the requirements for these desirable objects?

Firstly. A recognition of the fact that the signs obtained by means of auscultation and percussion are not directly diagnostic of particular diseases, but that they represent abnormal physical conditions which are common to a greater or less number of different diseases. The sign which approaches nearest to a pathognomonic significance, namely, the crepitant râle, does not exclusively belong to pneumonia. Signs which denote solidification of lung, namely, bronchial and broncho-vesicular respiration, increased vocal resonance, and bronchophony, are incident to various affections. The same is true of other signs. Given the presence of certain signs representing certain abnormal physical conditions in any case of disease, the diagnosis is to be determined by these signs taken in connection with the previous history of the case, and the present symptoms. It would be superfluous here to give illustrations, and I need hardly add, that this first requirement involves, in addition to a practical acquaintance with physical signs, knowledge of the important abnormal physical conditions which the signs represent, and of the relations of these conditions to the diseases in which they occur.

Secondly. It is to be acknowledged and borne in mind that positive proof of the diagnostic significance of the physical signs, as representing abnormal physical conditions, must be based exclusively on the constancy of the association of the latter with the former. The only solid foundation for practical knowledge of auscultation and percussion, thus, is on the facts obtained by clinical observation and by autopsical examinations, the facts from these two sources being ascertained in conjunction with each other. To establish physical diagnosis purely on the basis of principles of physics, is to build upon a sandy foundation. Not infrequently the conclusions concerning the significance of signs, logically deducted from physical data, are in direct conflict with facts derived from clinical observation. Reasoning *à priori* from the data of physics, the accuracy of observation is apt to be impaired. I would by no means imply that it is not desirable to explain, on the principles of physics, the connection existing between morbid physical conditions and their representative signs, but the diagnostic significance of the latter should in no way be thereby affected. It is useful as a means of corroborating and illustrating the significance of signs, to imitate, by artificial contrivances out of the body, as nearly as practicable, the physical conditions which the signs represent; and I hope to be able to show that the essential characters of nearly all the important signs obtained by auscultation and percussion may be artificially represented. I shall also introduce results of experimental observations which will show that many of the important physical signs may be profitably studied by making use of healthy and diseased lungs removed from the body. Most of the respiratory and vocal signs, as well as those obtained by percussion, may be reproduced after death by artificial respiration and the transmission into the air tubes of vocal sounds. The study of physical signs in this way is useful, in order to become familiar with their differential characters, and also with reference to the mechanism of their production.

The most unreliable course in forming judgments concerning the existence of certain morbid physical conditions, is to judge from the mental impressions produced by certain sounds, not heeding any well-defined characters of the latter. Here full sway is allowed to the imagination. The auscultator will be likely to find proof of physical conditions, the existence of which he had already inferred from the symptoms. Even Laennec's treatise is open to criticism on this score. Thus, he distinguished cavernous respiration as a sound giving an impression of air passing into a larger space than when the respiration is bronchial; he described pectoriloquy as complete when the voice seems to traverse the whole length of the stethoscope, whereas it traverses it partially when the pectoriloquy is incomplete, and the sign which he called a masked-blowing murmur (*souffle voilé*), was based on the idea of a movable veil between a cavity and the ear of the auscultator.

Thirdly. Individual physical signs are to be recognized as such only when their constant connection with distinct abnormal physical conditions has been established. This requirement is a security against an undue multiplication of signs by individualizing sounds which may be variations of established signs, or the significance of which has not been ascertained.

Fourthly. The differential characters of different signs would be distinct, clear, and simple. This requirement is of special importance as bearing on the true mode in which auscultation and percussion are to be studied. Naturally, the discoverer of auscultation was led to compare the sounds which he heard to those which are familiar. Hence, Laennec compared bronchial respiration to the sound of a current of air through a tube; œgophony to the cry of the goat; the crepitant râle to the crackling of salt on coals of fire; and the normal respiratory murmur to the sounds from the mouth of a person sleeping and breathing tranquilly. Skoda and others have undertaken to give an idea of auscultatory sounds by imitating them in the pronunciation, with the whispered voice, of different letters of the alphabet. A little reflection must, I think, render it evident that such comparisons cannot supply differential characters of the different signs obtained by either auscultation or percussion with that distinctiveness, clearness, and precision which are essential. There is but one way in which these differential characters can be made clear, distinctive, and precise. This is by means of what I have termed, by way of distinction, the analytical study of the sounds in health and disease. By the analytical study I mean, resolving the sounds into those elementary characters by which all sounds, natural or artificial, musical and non-musical, are practically discriminated. Now the chief differential points by which different sounds are distinguished from each other, relate to intensity, pitch, and quality. The distinctive characters of the sounds obtained by auscultation and percussion should be based mainly on points of difference derived from intensity, pitch, and quality. As thus derived, the differential characters may be made clear, distinct, precise, and also simple. Minor points of difference, which, however, are not to be overlooked, and in some instances are highly important, relate to the duration of sound, the rhythmical succession of inspiratory and expiratory sounds, and

the apparent distance from, or nearness to, the ear of the listener. More than thirty years ago, I was led to study the sounds obtained by auscultation and percussion with special reference to their variations in pitch. The results of the study were given in an essay which received a prize from the American Medical Association, and which was published in the *Transactions* of the Association of 1852.[1] I believe I was correct in commencing the essay by saying that "Very little attention has hitherto been paid to variations in the pitch of sounds heard in the practice of percussion and pulmonary auscultation." Although since that date increased attention has been paid to auscultatory sounds and those obtained by percussion, the distinctions pertaining to this source of differential characters, which were pointed out in that publication, have not, as yet, been fully and generally accepted. I have indicated, since the publication of that essay, additional distinctions which, as it seems to me, are of much importance in their applications to diagnosis. In treating of physical signs, in these lectures, it is but fair to my hearers to state that certain points of distinction relating to the pitch and quality of sounds originated in my own observations, and, on the other hand, it is but right to claim whatever merit may belong to my orignal observations.

Fifthly. The last requirement to be mentioned relates to nomenclature. The names by which the physical signs are designated, and the terms applied to their distinctive characters, should be correctly and clearly expressive. It is, of course, very desirable that the nomenclature should be uniform, as regards words and their meanings; in all countries. Words which denote theoretical views are objectionable. An example is the term "consonating," applied by Skoda to certain sounds produced by the breath, and the voice, and to certain râles. The term denotes not only a theory, but one the correctness of which is maintained by few, if any. The terms "full" and "empty," applied by the same author to sounds produced by percussion, convey no well-defined ideas, and it is not easy to understand what the author means by them after carefully reading his explanations. These terms are still in use by German authors, as also another singularly unsatisfactory term, namely, "indeterminate." Skoda applies this term to respiratory sounds which are neither bronchial nor vesicular, not attempting to give any positive, distinctive characters, and, indeed, declaring that this is impossible. I hope to show that it is not in the least necessary to use such a negative term as "indeterminate" in designating a group of respiratory signs. Such names as "wooden resonance," and "band-box resonance," are too loose to be appropriate. Especially objectionable is the designation of signs after the names of those who have described them. The names Williams, Skoda, Gerhardt, Biermer, and Wintrick have been introduced into the nomenclature of physical exploration by some German authors.

PERCUSSION.

It is usual to consider percussion before considering auscultation. The compass of the former is much the smaller, and its consideration prepares for that of the latter. Moreover, in the clinical employment of the two methods, percussion generally precedes auscultation.

PERCUSSORS AND PLEXIMETERS.

Auenbrugger was content with percussing by the fingers directly upon the thoracic parietes. The introduction of the plexímeter by Piorry was an improvement, but of vastly less importance than was claimed by him. It has perhaps never occurred to some of those present to practise immediate percussion. It will be found on trial less unsatisfactory, probably, than had been supposed. The credit of using a hammer, instead of the finger, as a percussor, is attributed to Wintrich. The hammer devised by him, and I believe still used in Germany, is a curiosity. As it has been but little used in this country, it may have interest in the way of novelty to some present, and I therefore exhibit it. As you see, the hammer part of the instrument, which is made of brass, is long and heavy. The point is tipped with India rubber. The handle is light and thin, with excavations to receive the ends of the thumb and fingers. It could hardly have been more clumsily devised to be used by striking directly upon the plexímeter. This was not intended; but the hammer is to be thrown upward by the movement of the hand in which it is held, and then allowed to fall upon the plexímeter. It is difficult to see in what respect this manner of percussing has any advantage over that in which the blows are made directly, and the disadvantages are obvious. It would not be profitable to discuss the different varieties of percussors which are in use with us. I shall simply show one which I have used for many years, and which I have found to answer admirably. It consists of a piece of India rubber in the form of a double cone, held in a ring at the end of a handle made of vulcanized rubber. It is light; it makes but little noise in coming into contact with whatever is used as a plexímeter, and it is durable.

I need not say that as both a plexímeter and a percussor, the fingers of the two hands answer every purpose in private practice. The chief object of an artificial plexímeter is to save the fingers from injury by frequent percussion. The plexímeter which I show I have used for some time. It is made of vulcanized India rubber, is light, easily held, and readily applied to the chest.

THE NORMAL VESICULAR RESONANCE ON PERCUSSION.

A thorough practical knowledge of the characters which distinguish the sounds in health is, of course, essential, as preparatory for the study of the morbid signs furnished by percussion and by auscultation. I have always found it difficult to enforce sufficiently this obvious truth in teaching medical students, and I suspect that with practitioners difficulty in the recognition of morbid signs is often attributable to an imperfect appreciation of the characters distinctive of normal sounds. Studied analytically, the characters which distinguish the normal resonance on percussion are resolvable into those derived from pitch and quality, inasmuch as the intensity varies in different persons and in different regions of the chest. Some exercise is necessary for a correct appreciation of pitch, as distinguished from quality, in the sounds obtained by percussion. Errors are sometimes attributable to a lack of this exercise. The relative variations in pitch are easily expressed by the terms high and low. On the other hand, the peculiar quality of any sound cannot be expressed in language. Let it be supposed, for example, that one should endeavor to describe the quality of the tones of a violin, or of any other musical instrument, to one who had never heard them. An idea of the quality of sounds can only be given by comparison, and it is rare for two sounds produced in different ways to resemble each other so closely that the one will give a clear idea of the other. Moreover, the variations in the quality of sounds are innumerable. As an illustration, let it be considered that the human voice has so many diversities, irrespective of pitch and intensity, that among many thousand persons it would be difficult to find two voices precisely alike. Hence, the peculiar quality of

[1] This essay was entitled "On Variations of Pitch in Percussion and Respiratory Sounds, and their Application to Physical Diagnosis."

sounds must be learned by direct observation. Now, as regards the pitch and quality of the normal pulmonary resonance, the quality is *sui generis*. It cannot be described. Evidently the quality is dependent on the fact that the air which gives the resonance is contained in the pulmonary vesicles or alveolæ, and not in a free space, and, for this reason, the name *vesicular*, which is used to distinguish this peculiar quality, is appropriate. The pitch, as compared with the abnormal sound obtained by percussion, is low. I believe I am correct in saying that no abnormal sound obtained by percussing the chest is ever lower in pitch than the normal vesicular resonance in the same subject. The pitch of the normal resonance is evidently determined by the same physical conditions to which the vesicular quality is attributable, for the pitch is lower in proportion as this quality is marked, and *vice versa*.

In order to represent, artificially, vesicular resonance, an article must be found which resembles lung in the essential physical condition, namely, containing air in innumerable minute spaces. A feeble imitation is obtained by percussing a sponge. My friend, Dr. J. S. Thatcher, has suggested a much better article—a loaf of bread. Bread in the form of a loaf gives a resonance of considerable intensity, and it is a fair representation of the vesicular resonance. It should be covered with a cloth in order to diminish the noise produced by the contact of the fingers or the percussor, and thus to elicit better the sound from the air contained in the interstices of the loaf. The upper crust stands in place of the thoracic wall. The resonance elicited illustrates the lowness of the pitch, with a pretty close approach to the peculiar quality of the normal pulmonary resonance.

When it is considered that all the knowledge furnished by percussion, which is available in the physical diagnosis of pulmonary diseases, may be comprised in four signs, one is led to exclaim, What is to hinder the possession of this knowledge to the fullest extent by every practitioner! There is no hindrance beyond unanimity in the recognition of the existence of these signs, and that practical acquaintance with their differential characters which requires but a very moderate amount of time and attention. Arranged in pairs, the four signs are, 1st, flatness and dulness; 2d, tympanitic and vesiculo-tympanitic resonance.

FLATNESS AND DULNESS.

The first pair represent different degrees of the same morbid physical conditions, namely, either the presence of liquid in the pleural cavity, liquid in the vesicles, or in the interstitial lung tissue, or solidification of lung incident to pneumonia, phthisis, pleurisy, and other affections, or morbid growths within or extending into the intra-thoracic space. It is to be understood that the term flatness means no proper sound or resonance. It is absence of sound. It cannot be defined more distinctly than by this statement. There can, of course, be no degrees or variety of flatness.

In dulness, the resonance is more or less diminished. There are degrees varying from the slightest diminution to that approximating as closely as possible to flatness. Flatness has, of course, neither pitch nor quality of sound. Dulness, considered as a distinct sign, always has more or less of the quality which belongs to the normal resonance, that is, the vesicular quality. If this quality be entirely wanting, the resonance is tympanitic, as will presently be seen. A fact which I pointed out in my essay published in 1852, is that in dulness the pitch of sound is invariably higher than that of the normal resonance of the person examined. This fact is of importance, as assisting in the recognition of a slight degree of dulness. It is of much importance in certain cases which will be referred to in connection with vesiculo-tympanitic resonance. The elevation of pitch now generally enters into the account given by medical writers of dulness or percussion, which it did not prior to 1852.

The essential distinction in the other pair of signs, namely,

TYMPANITIC AND VESICULO-TYMPANITIC RESONANCE,

relates to quality of sound. In a purely tympanitic resonance, there is complete absence of the vesicular quality which belongs to the normal resonance. Conversely, a resonance in which the vesicular quality is absent is always tympanitic. This sign represents the following morbid physical conditions: air in the pleural space, pulmonary cavities, solidification of the upper lobe of a lung, the resonance then being derived from air in the extra-pulmonary bronchial tubes, and conduction of resonance from the stomach or colon.

The tympanitic resonance, as just distinguished, is artificially reproduced whenever resonance is derived from air in a free space of greater or less size, instead of being derived from air in a collection of minute spaces like those of the pulmonary vesicles, or the interstices of the bread-loaf. The intensity of the resonance will depend on the amount of free air, the thickness, elasticity, and tension of the walls of the space containing the air, and other circumstances, aside from the force of the percussion. However feeble and distant, the resonance is always tympanitic if it be devoid of that peculiar quality due to the fact that the air is in minute spaces, namely, the vesicular quality. It is, perhaps, a common impression that for a resonance to be tympanitic, it must be louder than the normal resonance. Intensity is an unimportant element so far as regards the distinctive characters of the sign. It may have any degree of gradation between much intensity and great feebleness of sound. Air in the pleural space frequently yields a tympanitic resonance which is notably intense. As a rule, the resonance is comparatively feeble over a pulmonary cavity, and where derived from air in the extra-pulmonary bronchi, the sound being conducted through solidified lung.

A tympanitic resonance is invariably higher in pitch than the normal resonance. I believe this statement to be correct, although the reverse is stated by some medical writers, who are in error, as I suppose, either from reasoning incorrectly on principles of physics, or from not accurately distinguishing pitch from intensity and quality. The latter mistake is liable to occur without some training of the ear, and careful attention. It is by no means as easy to distinguish variations in the pitch of non-musical sounds as of musical notes. Some exercise is requisite to secure accuracy, and the discrimination is undoubtedly somewhat difficult for those who have not what is called a "musical ear."

Other things being equal, the pitch is lowered the larger the free space containing air. The bass-drum has a notably lower tone than the kettle-drum, and the non-musical resonance from an inflated bladder or an India-rubber bag of considerable size, is lower than that from a small hollow India-rubber ball. Percussion over a flatulent cæcum gives a higher pitch of resonance than over the stomach; the pitch of resonance over the colon distended with gas is lower than the resonance from either the stomach or cæcum, and the resonance over the small intestine is still lower. Tension has much to do with pitch; this is shown by the effect of tightening a drum-head. The effect of the difference in the material of the walls of the space enclosing air, upon the pitch and intensity, is shown by comparing the sounds produced by beating a drum on its head and on its sides. The many variations corresponding to those in the physical conditions which give rise to tympanitic resonance, may have interest for some who

are curious as regards the *minutiæ* of acoustic phenomena, but, if two varieties to be presently noticed be excepted, the variations in tympanitic resonance are of no utility in their practical applications to physical diagnosis. They are burdensome and perplexing to the student of percussion who desires only to acquire the knowledge which is practically useful. One who wishes more than this will find in the treatise by Eichhorst on the *Physical Methods of Investigating Internal Diseases*, enough to gratify curiosity respecting minute and superfluous details.

A practical point of importance pertaining to tympanitic resonance, is its ready conduction for a greater or less distance beyond the limits of the space whence it comes. In this respect it differs notably from the normal vesicular resonance. A gastric tympanitic resonance is often conducted upward over a considerable portion of the thorax on the left side. In like manner, the resonance from the colon may extend as far as, or even above, the upper boundary of hepatic flatness. It follows that this resonance is unreliable for determining with accuracy the lower border of the liver, the boundaries of the spleen, and the space occupied by abdominal tumors.

AMPHORIC AND CRACKED-METAL RESONANCE.

Tympanitic resonance, with either an amphoric or cracked-metal intonation, claims but a passing notice. The familiar illustrations of these varieties by filliping the cheek made more or less tense, and by striking the closed hands upon the knee, cannot be improved upon. The intonations may be produced by percussing India-rubber hollow balls of different sizes. Clinically, the fact that the intonations are sometimes heard on percussing over the solidified upper lobe of the lung in situations over the extra-pulmonary bronchi, is not to be overlooked. And the fact that, with this exception and the rare instances in which in these situations they are found in health, they are invariably cavernous signs, renders them of much value in diagnosis. Another practical fact is perhaps not always appreciated, namely, that these intonations may very often be perceived by the ear close to the open mouth of the patient, when otherwise they escape observation. Still another fact deserves mention. With the pectoral extremity of the binaural stethoscope close to the open mouth of the patient, they may be recognized when they are not readily perceived without this instrument. Finally, it is to be borne in mind that they are found at some times and not at other times, owing to the varying condition of cavities as regard emptiness, and of the bronchial tubes as regards freedom from obstruction.

The last of the four signs is the

VESICULO-TYMPANITIC RESONANCE.

I must hold myself responsible for the name and the description of the characters distinctive of this sign. The name expresses the most diagnostic feature. The vesicular and the tympanitic quality are combined in varying proportions. An essential feature, however, is an increase in intensity. The intensification may be greater or less in degree. The pitch of the resonance is invariably raised. It is raised in proportion as the tympanitic predominates over the vesicular quality. This sign is therefore distinguished from the normal resonance by the presence of more or less of the tympanitic quality of sound, by greater intensity, and by a higher pitch. It is distinguished from the tympanitic resonance by the presence of more or less of the vesicular quality of sound. It is distinguished from dulness by its intensity. The only difficulty in its recognition practically, pertains to its discrimination from tympanitic resonance. The predominance of the tympanitic quality, with a proportionate elevation of pitch, may be so great that it may seem to be purely tympanitic. This error may always be avoided by attention to coexisting physical signs. The sign represents an abnormal accumulation of air within the air-cells. It is, therefore, *par excellence*, the sign of pulmonary emphysema. Its practical value in diagnosis is chiefly in that pathological connection. It occurs, however, in other pathological connections. It is this sign which is obtained above the level of liquid when the quantity is sufficient to fill a third, a half, or even two-thirds of the thoracic space, be the liquid either serous or purulent. It is obtained in cases of pneumonia affecting one lobe of a lung, over the unaffected lobe of the same lung, be the latter either the upper or the lower lobe. I forego discussion of the question, wherefore is the sign present in these two pathological connections, simply stating that I suppose in either instance there is an abnormal accumulation of air and increased tension of the alveolar walls within the lobes which yield the sign.

The vesiculo-tympanitic resonance may be illustrated by means of the human lungs, or those of the calf or sheep, removed from the body; inflated artificially within the limit of a normal inspiration, the resonance represents the normal vesicular. Inflated considerably beyond that limit, the emphysematous condition is produced, and the resonance represents that condition.

There is a liability to error in the non-recognition of this sign in certain cases of pulmonary emphysema; and, consequently, to an unfortunate mistake in diagnosis. As a rule, in emphysema, the upper lobes of both lungs are affected, and the lobe of the left in a greater degree than that of the right lung. Now, under these circumstances, the upper lobe in both lungs yields a vesiculo-tympanitic resonance, but this sign is more marked on the left than on the right side, the difference corresponding to the difference in the degree of emphysema. The error is in regarding the lesser degree of resonance on the right, compared with the greater degree of increased resonance on the left side, as dulness which, taken in connection with the symptoms, would point to a phthisical affection. This error of observation, and consequent mistake in diagnosis, is a not very infrequent occurrence. The relatively lesser degree of resonance on the right side at the summit of the chest, which is supposed to be dulness, is, in fact, a vesiculo-tympanitic resonance, and the intensity is therefore greater than normal. The intensity seems to be diminished because it is relatively less than the still greater intensity on the left side. The error is avoided by attention to the pitch and the quality of the resonance on the two sides. If the disparity in respect of the intensity of resonance be due to a greater amount of emphysema on the left side, the pitch of the sound will be higher on that side than on the right side, and the quality will be distinctly vesiculo-tympanitic. On the other hand, were the disparity due to dulness on the right side, the pitch of sound should be higher on that side than on the left side, and the vesicular quality of the resonance on the left side should be without admixture with a tympanitic quality. A useful practical exercise is to select two patients, one affected moderately with emphysema, and the other with a moderate phthisical affection at the summit of the right lung. In the case of phthisis, the resonance at the summit of the right side of the chest will be less than on the left side, and higher in pitch, the resonance on the left side being vesicular in quality, and lower in pitch. In other words, there is abnormal dulness on the right side. In the case of emphysema, the resonance at the summit of the chest on the right side, as in the other case, will be less intense than on the left side; but the disparity is due, not to a diminished in-

tensity of the resonance on the right side, but to the greater increase of its intensity on the left side; and this increased intensity is accompanied by a vesiculo-tympanitic quality, and a higher pitch than on the right side. That in this case the resonance on the right side is actually increased; in other words, that on the right, as well as on the left side, the resonance is vesiculo-tympanitic, is shown by a comparison of the resonance over the upper with that over the lower lobe. In cases of emphysema, the standard of health, or an approximation thereto, is obtained by percussion over the lower lobes.

ARTIFICIAL ILLUSTRATIONS OF THE SIGNS OBTAINED BY PERCUSSION.

In conclusion, I hope it will not be deemed too trivial a matter for this occasion, nor an unworthy use of the "staff of life," to show how the signs obtained by percussion may be illustrated by imitating, out of the body, simply and roughly, the morbid physical conditions which these signs represent, using for this purpose, chiefly, the bread-loaf. A resonance analogous to the vesicular, as has been stated, may be produced by percussing a loaf of bread. The first of the four abnormal signs, namely, flatness, is easily enough illustrated. Any substance devoid of air suffices for an illustration. If a part of a loaf of bread be immersed in water for a few moments, the interstices become filled, and we have an imitation of pulmonary œdema; over that portion of the loaf there is flatness. If the absorption of water be not sufficient to fill the interstices, there is dulness. A single loaf may thus be made to illustrate flatness, dulness, and the normal resonance. If, for water, a solution of gelatine be substituted, and a part of a loaf be allowed to remain immersed until the gelatine congeals, we obtain a representation of solidification of lung analagous to that in cases of pneumonia. The three above-named signs may in this way be illustrated.

Dulness may be illustrated and compared with an imitation of the normal resonance, by introducing into one-half of a loaf of bread pieces of some solid material. In the present illustration I use sticks of candy. The elevation of the pitch of the dull sound may in this way be shown.

Tympanitic resonance is familiar, of course, from the percussion of the abdomen. The pitch, other things being equal, is higher the smaller the space containing air or gas. Artificially, a bladder, or an India-rubber bag inflated, gives an illustration of a tympanitic resonance. Comparing the resonance of an inflated bag of large size, with the resonance of an inflated lung, the higher pitch of the former may be observed. It is also shown by comparison with resonance from a loaf of bread.

Amphoric and cracked-metal resonance may be illustrated by percussing an India-rubber bulb, such as is used in Davidson's syringe, held down to the ear. It will be seen that the cracked-metal intonation requires a small space with free openings.

Tympanitic resonance within a circumscribed space is shown by removing a portion from the centre of a loaf of bread, leaving only the crust. The resonance over this space may be contrasted with that over the remainder of the loaf. By immersing the loaf for a few moments in water, the tympanitic resonance is brought into contrast with flatness on percussion.

Circumscribed flatness may be shown by filling the space which had given the tympanitic resonance with some solid material. Dough containing no air is a good material for this purpose.

The vesiculo-tympanitic resonance may be artificially illustrated as follows: Take a common loaf of bread. By means of a hollow cylinder remove longitudinal sections in one-half of the loaf. The spaces thus produced yield a tympanitic resonance, and the portions of bread which remain give the vesicular resonance. The vesicular and the tympanitic quality are thus combined with elevation of pitch, the tympanitic quality and the elevation of pitch corresponding to the number of sections removed.

A CASE OF SARCOMATOUS "INFLAMMATORY FUNGOID NEOPLASM."

BY LOUIS A. DUHRING, M.D.,
PROFESSOR OF SKIN DISEASES IN THE UNIVERSITY OF PENNSYLVANIA.

THE following case of this rare and grave disease presented itself at my clinic for diseases of the skin at the University Hospital, on Novemer 14, 1882. The patient was exhibited to the class and the prominent features of the affection pointed out in the course of the lecture. The disease is of such rarity and interest as to entitle the case to a place on record, and I shall therefore, without further preface, briefly describe the most important symptoms. The history (for which I am indebted to Dr. Van Harlingen) states that the man, Charles Coyne by name, is a laborer, fifty-two years of age, and a native of Ireland. He enjoyed good health until he was thirty years old, when he was attacked with eczema of the hands, which gradually invaded the feet and other regions until in a short time almost the whole surface became involved. The eczema was always dry and slightly scaly, and itched severely.

About eight years ago the disease under consideration made its appearance in the form of a pea-sized tubercle situated over the left eyebrow. It was at first the same color as the surrounding normal skin, but afterwards became pale-red, and later somewhat purplish in shade. It, as well as all subsequent lesions, from the beginning, itched violently. It grew gradually, so that by the end of a year it was as large as a hazel-nut, and has since increased to its present size. About a year after the appearance of the tubercle referred to, a similar growth came upon the right eyebrow, which has followed the same course. Later, like formations, symmetrically disposed, manifested themselves behind the ears and the jaws, and several years afterwards they also made their appearance on the chest, and later on other parts of the trunk. On the chest there first appeared a highly inflammatory papular eruption, "resembling prickly heat," which after vanishing was succeeded by the present papular, tubercular, and nodular formations. Latterly, a few of the older lesions have softened and ulcerated superficially, but this tendency is as yet not marked. The hemorrhagic symptoms, seen on some of the patches of the trunk and in places on the extremities, have existed only during the past six months. The general health has been gradually failing, and he has lost weight during the last year. He is now in poor health; is spare and somewhat emaciated, and is weak.

Occupying the eyebrows and forehead are two

perfectly symmetrical, circumscribed, irregularly shaped, lobulated tumors the size of common hen's eggs. They are soft, fleshy, and have a fungoid look, and are of a dusky, dull, pale-red or violaceous color, and have slightly excoriated and scaly, rough surfaces, the result of scratching. They are irregularly ovoidal in shape, and project about an inch beyond the forehead, giving a heavy expression to the face. Upon the surface of either growth there exist several furrows or linear depressions. The color is a dull-red with a purplish tint, —a pale raspberry-red.

Immediately above the tumor on the left side there is a flat, almond-sized and shaped, pale-pinkish formation, which when taken between the fingers is found to be defined in outline and firm in consistence. It is seated in the skin and subcutaneous connective tissue. It illustrates the earliest stage of the tumors

On either side of the head, occupying symmetrically the region in front of and behind the auricles, there exist extensive, highly developed masses of firm infiltration, having the same general character as the tumors of the eyebrows. The disease here extends from the temporal region down to the angles of the lower jaw, and is so pronounced as to cause considerable deformity. Behind the auricles it extends into the scalp as far as the parietal region, and thence on either side to the occipital protuberance. The posterior aspect of the neck is also similarly invaded. The whole mass is considerably raised and is irregularly furrowed, tuberculated, and nodulated, though not to the extent of the prominent tumors, such as those on the face.

In addition to the lesions described, there exist numerous, variously sized, rounded or flat, raised patches of infiltration, of a reddish-purple or brownish-red shade, scattered over the trunk, the most conspicuous of which are seated on the chest. These are five in number, two occupying the region of the nipples, and the others the sternum. They are large and prominent, varying in size from a walnut to an egg, and have a firm, fleshy feel, and a distinctly fungoid appearance. Upon various regions of the trunk, small and large, ill-defined patches of an inflammatory papular eruption (resembling disseminate papular eczema) exist, the seat of violent itching. More or less of this eruption is found over the whole surface, and appears to be eczematous in character, although peculiar in type. The general color of the skin of the trunk is a dusky-red, mottled, and in places violaceous or even bluish (hemorrhagic) in tint.

Upon the arms and forearms are likewise patches of tubercular infiltration, and also of the inflammatory papular manifestation, some of them being distinctly hemorrhagic. Upon the thighs and legs there are no large tumors or nodular formations, but here and there are patches of diffuse and papular infiltration, all of which are markedly hemorrhagic, so much so as to give the picture of purpura. Upon the hard palate, involving the uvula, is an elongate, circumscribed, raised, plate-like patch of infiltration, about half an inch in diameter. The voice is in consequence thick. The cutaneous lesions are all accompanied by intense itching, which is almost constant. The scratch-marks, everywhere visible, attest this statement, and it is chiefly for this symptom that the man now seeks medical advice.

The case represents the same disease that I brought before the American Dermatological Association four years ago, a full report of which case, together with the remarks made by the writer, and by members of the Association, may be found in the *Archives of Dermatology*, January, 1879, and January, 1880, with the provisional title of "inflammatory fungoid neoplasm." The inflammatory nature of the process was more marked in the first case than in the present one, although some of the lesions cannot be interpreted otherwise than as highly inflammatory. We shall find, however, without doubt, in the fully developed tumors the same formation as existed in the first case, viz.: a dense, small, round-cell infiltration involving the cutaneous and subcutaneous tissues, possessing the general features of sarcoma. The disease is liable to be confounded clinically with syphilis and with cancer, although the microscope would at once differentiate it from the latter disease. The prognosis is grave, for although the progress of the disease up to the present time has been slow, it will surely be more rapid within the next few years, and will prove fatal.

On the subject of treatment, I have but little to say. The various anti-pruritic remedies that are found useful in papular eczema, such, for example, as thymol, carbolic acid, and the tarry preparations, will in a measure relieve and control the itching. The larger growths that occasion inconvenience may be removed with the knife, or, where possible, by the galvano-cautery wire, a much better method of operation. The tumors are vascular, and by means of the galvano-cautery the annoyance from hemorrhage is lessened. The wound will probably heal without difficulty, and a recurrence of the growth at the point of the incision need not be feared, this opinion being based on my experience in the other case referred to.

THREE CASES OF DIABETES INSIPIDUS SUCCESSFULLY TREATED BY ERGOT.

BY C. S. LACY, M.D.,
OF MACEDON, N. Y.

WITH the view of adding further evidence in favor of the value of ergot in the treatment of diabetes insipidus, I desire to record the following cases:

CASE I.—J. S., æt. 18, family history good, and he had previously enjoyed good health, consulted me Sept. 10, 1877, "for some trouble with his kidneys." Some four weeks before he had attended a festival, and indulged in ice cream quite freely, and, as he expressed it, "had not been well since," having passed large quantities of urine ever since, being obliged to get up in the night several times to micturate. Urine very light colored, acid reaction, specific gravity 1005, neither albumen nor sugar. The amount voided during twenty-four hours was 180 ounces. Put him upon valerian four times daily.

Sept. 25.—Passed 220 ounces of urine, specific gravity 1008. He had become very much weakened, pale, and emaciated; loss of appetite; pain in the small of the back. In consultation with Dr. B., determined to try bromide of potassium 15 to 20 grains, three times daily.

Oct. 10.—Urine passed, 250 ounces; no traces of albumen or sugar; face and ankles œdematous; great weakness and prostration, shortness of breath; indigestion, with acid eructations. He and his friends had given up all hopes of his recovery.

In looking over my journals with a view of finding some new "points" upon the treatment of this case, I found in the August number for 1875, of the *Monthly Abstract of Medical Sciences*, Dr. Da Costa's account of a case treated by ergot. The 15th of October I put him upon drachm doses of the fluid extract of ergot, three times daily, and increased to two drachms, three times daily. Its effects were marvellous, there being a steady diminution in the daily amount of urine voided, and a marked improvement in the patient's health. He may be said to have been well the first of January, 1878. There was a steady decrease in the amount of urine from the first giving of the ergot. The amount passed at the time I began giving the ergot, Oct. 15th, 240 ounces; Oct. 18th, 195 ounces; Oct. 25th, 130 ounces; Nov. 2d, 100; from this time to the 1st of Jan. the highest amount passed was 80 ounces; Nov. 20th, and from the time I ceased treating him, Jan. 1st, 1878, to the present time, he has been a well man, and, as over four years have elapsed, I think we are warranted in claiming for ergot the credit of the cure.

The history of the other two cases which I have to relate only confirm the efficacy of ergot in the treatment of diabetes insipidus.

CASE II.—Young man, 23 years of age, farmer, of good family history; had been troubled two months when he consulted me. June 15, 1879, he passed on an average 160 ounces of urine daily, slightly acid in its reaction; specific gravity, 1003; no traces of albumen; no sugar. He said that he first noticed the trouble after some heavy work—plowing, etc.; troubled with indigestion; bowels constipated; no disease of heart, lungs, or other organs; temperature normal; and he complained of nothing but a "tired feeling," being very much prostrated; pale and emaciated, having lost some twenty-five pounds in weight during the two months. The amount of urine voided corresponded nearly with the amount of fluids taken. Ordered him to take drachm doses of the fluid extract of ergot four times daily, and gradually increased the quantity to two drachms three times daily. Much improved in a few days. Not obliged to get up at nights to micturate; and, as he expressed it, "felt like a new man." Upon the fifteenth day of treatment the amount of urine passed was 80 ounces; thirtieth day, normal; and from the day I ceased treating him, the 20th of August, 1879, to the present time, he has been a strong, robust man.

CASE III.—J. R., a boy, some twelve years of age. His mother has asthma; otherwise the family history is good; and up to the time of my treating him, March 10, 1880, he had been a very healthy child. His parents had noticed for some time that he passed more urine than seemed natural, having to get up during the night several times to micturate; was becoming pale and emaciated; no life or ambition; complained of weakness in back, loss of appetite, etc. His parents attributed his condition to his growing rapidly; but, finding he did not improve, brought him to me. There was no disease of any of the organs. He passed from eight to ten pints of urine daily, which far exceeded the amount of fluids taken. Specific gravity, 1005. He being very fond of milk, I put him upon a milk diet almost exclusively; gave him ergot, half drachm, four times daily; increased to one drachm; also gave cod-liver oil three times daily; very much improved at the end of the tenth day; did not have to get up during the night; and the amount of urine passed was four pints; and from that time until the middle of May, 1880, he improved. Urine normal; appetite good; gained in flesh, so that he did not look at all like the pale, puny boy that first visited me. He has enjoyed good health up to the present time, with the exception of a severe attack of dysentery, in the fall of 1881, from which he made a good recovery.

I think these three cases will go far to establish the claims of Dr. Da Costa for ergot. In the treatment of diabetes insipidus, like him, I do not contend that it will always cure, but that it merits the fullest confidence in this disease.

HOSPITAL NOTES.

BOSTON CITY HOSPITAL.

(Service of W. C. B. FIFIELD, M D.)

SCIATICA CURED BY STRETCHING THE SCIATIC NERVE.

(Reported by ROYAL WHITMAN, M.D., House Surgeon.)

THE patient, a native of Boston, 39 years of age, entered the hospital October 19, 1882. His history was as follows:

His first attack of sciatica occurred in 1872, and was induced, he thinks, by exposure to wet while working at his trade, that of a piano polisher. Each winter since this time, he has been confined to the house from three to six weeks with attacks of sciatica in the right leg, which have gradually increased in severity. Last July he had an attack of unusual severity, for which he entered the medical side of the hospital. At this time he could not fully extend the leg on account of the stiffness and pain, and was obliged to walk in a stooping position. He remained at the hospital for six weeks, and was then discharged partially relieved, on crutches. He remained at home for five weeks, and then re-entered the hospital. At this time he was unable to dress himself on account of the extreme pain in the leg and stiffness in the back. He remained seven weeks, and was then discharged partially relieved. He continued in about the same condition during the summer, being unable to walk without crutches.

He was then treated at the out-patients' department of the Massachusetts General Hospital, where ether was given, and an attempt made to stretch the nerve by forcibly flexing the leg upon the body. This was, however, followed by no relief, and the operation of

stretching the nerve was advised, and he accordingly entered the hospital. At this time his pain was intense, and the patient, as he expressed it, "longed to have a knife put into his leg." On the following morning ether was given, and Dr. Fifield made an incision six inches in length, commencing at a point two inches below the tuberosity of the ischium, over the biceps muscle. This muscle, with the semitendinosus, was drawn to the outside, and the nerve was exposed. A sound was then passed beneath it, and it was pulled three times with sufficient force to lift the leg from the table. There was no hemorrhage. The wound was united with deep silver sutures. The operation was done under spray, and occupied but a few moments.

Upon the following day the course of the sciatic and its larger branches could be traced by lines of ecchymoses under the skin. The wound healed rapidly, and the patient was discharged well on the nineteenth day after the operation. There has been no pain or stiffness since; and the only abnormal sensation noticed was a slight numbness in the calf of the leg.

MEDICAL PROGRESS.

NERVE-STRETCHING IN LOCOMOTOR ATAXY.—In the *Revue de Médecine* (Nos. 10 and 11) there is a critical review of the results of nerve-stretching in locomotor ataxy and other diseases of the spinal cord. With the latter class of cases we have at present nothing to do, but we think the results of inquiry into the former class of cases ought to be made known. In the review mention is made of 54 cases, published in various parts of the world, where the sciatic nerve was stretched for locomotor ataxy. Of these no fewer than 6 died, and in 3 cases the death was directly attributable to the operation. In 19 instances the patient derived no benefit whatever from the operation. In 18 instances there was either alleviation of one or more symptoms or some temporary benefit, or there was immediate benefit from the operation but the ultimate result was not known. In the remaining 11 cases a lasting improvement was noted. Thus the outcome of this inquiry is that in about 54 per cent. of the cases the operation was followed by permanent or temporary benefit, and in 46 per cent. no good resulted from the operation, death ensuing in 11 per cent. of the cases. We must note the fact that in one instance Langenbuch had twice performed this operation with some benefit when the patient died after the third operation, and Westphal found the spinal cord perfectly healthy. This certainly was not the case in any of the fatal cases referred to above, but we can not help feeling that there is a possibility that some of these successful cases were not really cases of disease of the spinal cord at all. The operation is one which has not found much favor in this country, and in London it has found very few advocates indeed. We think the statistics we have given above will not tend to increase the favor of the operation in the eyes of those who make the welfare of their patients their first consideration.—*Medical Times and Gazette*, December 2, 1882.

CARDIAC FORM OF TYPHOID FEVER.—PROF. BERNHEIM, of Nancy (*Lyon Méd*, Oct. 8, 1882) read a paper before the French Association on this subject. He distinguishes between the cardiac form proper, as he calls it, and those other forms of typhoid in which the symptoms of cardiac disease are simulated, or in which disturbances of the pulmonary circulation are manifested. His cardiac form is marked by an acceleration of the heart's rhythm, without any organic lesion. The increased frequency of the pulse is not accompanied by any proportionate elevation of temperature. The symptoms appear at the beginning of the attack, and are due to a toxic action of the typhoid poison on the motor centres of the heart itself. It is a rare form. Bernheim has only met with six instances among 250 cases. On the other hand, it is a very grave form. No advantage is obtained by administering stimulants like alcohol and ether, and the use of digitalis is dangerous.—*Practitioner*, December, 1882.

TRICUSPID CARDIAC MURMURS HEARD AT THE APEX.—DR. DUROZIEZ has studied a number of cases in which there were tricuspid murmurs, and states that ordinarily tricuspid murmurs can be heard over all the surface of the right ventricle, that is to say, over all the anterior surface of the heart. The points of maximum intensity vary, sometimes being below the sternum, sometimes at its inferior border, and sometimes at the apex. When only heard at the apex, they are often wrongly attributed to the mitral valve; the latter murmurs, however, are also to be heard in the axilla and in the back, while the tricuspid murmur is never to be heard to the left of the apex, in the axilla, or in the back.

Since the right ventricle, equally with the left, contributes to the formation of the apex, there is nothing to prevent tricuspid murmurs being audible at this point. A tricuspid murmur may exist without a venous pulse, and *vice versa*. A humming murmur is more frequently tricuspid than mitral, and indicates a very narrow insufficiency and energetic ventricle.—*L'Union Médicale*, November 26, 1882.

TRACHOMA.—At the recent meeting of the Ophthalmological Congress at Heidelberg, PROF. SATTLER made a communication upon the origin of trachoma, which he believes to be caused by micro organisms. His more recent experiments have fully borne out the results he obtained in 1881, which were read before the Heidelberg Congress in September of that year. He has again succeeded in cultivating the micrococci, and producing positive results by inoculation. The organisms are circular, are never seen with zoöglæa, but always singly or in pairs, separated by a small interspace. Inoculation of the third generation of a cultivation produced trachoma in the human conjunctiva. These micrococci alone produce trachoma; all other substances used failed to do so.

In the discussion which followed, Baumeister and Kerschbaumer advocated the use of iodoform in contagious conjunctival affections. Samelsohn remarked that he had seen the bacillus of tubercle in tuberculosis of the iris, and Leber that he always now finds micrococci in hypopyon keratitis.—*Ophthalmic Review*, December, 1882.

SYPHILITIC ENLARGEMENT OF TONSILS.—An abstract of the conclusions of DR. PAUL HAMONIC is to be found in the *Deutsche Med. Zeitung*, No. 45. Hamonic distinguishes, during the secondary stage of syphilis—1. *Simple hypertrophy*, which is analogous to the swelling of lymphatic glands, is tardy in its development, and as it occasions no symptoms, is often overlooked. Both tonsils are almost always affected, though to a different degree. The enlargement takes place forwards, bulging the anterior pillar of the fauces, and rarely gives rise to deafness. The tonsils are hard and somewhat elastic; the normal depressions on their surfaces are exaggerated. The uvula tends to go over to the larger tonsil. Sometimes the tonsil may be reduced in size by anti-syphilitic treatment. 2. *Hypertrophy associated with angina.* In this there is not so much fever as in ordinary acute angina; the duration is variable, and relapses are very liable to happen. 3. *Hypertrophy complicated with syphilides.* Most fre-

quently the syphilide appears on the tonsil and the anterior pillar of the fauces. When syphilis affects a previously scrofulous tonsil the enlargement is very great, of pale color, often spongy and with large crypts, there is considerable pain, the voice becomes nasal, and the hearing, taste, and smell are altered. The course is generally chronic, and there is a great tendency to recurrence. Ordinary tonsillitis and sore throat may supervene even when the tonsils are syphilitically enlarged, but then, though peritonsillar suppuration may occur, it would appear that the tonsil itself never suppurates. Hamonic states that there is no objection to excision of the syphilitic tonsils if they be very large. —*Medical Times and Gazette*, December 2, 1882.

Gastrotomy in Extra-uterine Pregnancy.—Dr. N. Phenomenon (*Arch. de Tocologie*) reports the case of a peasant woman 22 years of age, who illustrated this accident. She began to menstruate at seventeen years of age, and this function was always performed regularly and normally. She married at eighteen years of age and continued in good health: she came to the author's clinic in January, 1881. Twenty-two months previous to that time the menses first failed to appear. The customary symptoms of pregnancy followed, even to the perception of fœtal movements. Before the expiration of the customary nine months of gestation, the fœtal movements became more feeble, she experienced severe pains in the kidneys and in the lower part of the abdomen, and occasional paroxysms of fever. The time for delivery arrived, but no labor-pains appeared. The abdomen continued to increase in size for a month or two longer, and then remained *in statu quo*. During the first three-fourths of the year which followed she had occasional attacks of fever and in the intervals was able to attend to her household duties and even to work in the field. Then an abscess formed and pointed at the navel, and a quantity of pus was discharged. Extreme weakness followed, and in this condition she appeared at the author's clinic. The tumor presented the following characteristics: 1st. Its contour was very well defined. 2d. It was solid. 3d. It crepitated upon palpation. 4th. It was painful to the touch. 5th. It was immovable, but was not attached to the abdominal walls. A fistula existed at the navel, from which pus exuded. The diagnosis made was that of abdominal pregnancy. The abdomen was opened by M. Horwitz, and the cyst was found to have no adhesions anteriorly of any extent. The putrefied fœtus was removed, and the cyst, which was firmly fixed at its sides, was secured by the sutures which closed the abdominal wound. The operation was performed with antiseptic precautions, and the patient made a good recovery.

As deductions from this case the author observes: 1st. If the pregnancy continues through the customary period without mishap, there is no occasion for interference, providing always that watchfulness against accidents is to be observed. This is contrary to the opinion of Güsserow, who advises operation at the beginning of the eighth month. 2d. In case of the occurrence of some grave, complicating accident, equally dangerous for the fœtus and for the mother, as, for example, rupture of the fœtal sac, or internal hemorrhage, gastrotomy is indicated to be performed at once. This is contrary to Spiegelberg's experience and advice, and Parry estimates that seventy per cent. of the mothers die after such operations. The author replies that statistics are not reliable, for the cases are never identical where the operation has been performed. 3d. If the normal period of pregnancy has passed, the fœtus has died, and the case is presented to us for decision, the course of action must vary in accordance with the pathological process, which differs in every case. Two issues are customary with such pregnancies, petrification or the conversion of the fœtus into calcareous material, and a slow process of suppuration by means of which the contents of the fœtal sac are discharged through fistulous openings. The former is the more desirable end, for it does not tax the vital resources as the latter does. The author does not believe in waiting for the formation of a fistula before operating, especially when the cyst is near the abdominal wall. One must always remember the grave complications which are possible if the cyst is allowed to suppurate. Of the active or the passive modes of treatment, then, the author is decidedly in favor of the former.—*Amer. Journ. of Obstetrics*, December, 1882.

The Diagnosis of Pulmonary Syphilis.—In the *Wiener Medizinische Wochenschrift*, No. 46, an abstract of an alleged case of pulmonary syphilis may be found recorded by Dr. Guntz. The previous history of the man showed that two years after infection an eruption appeared on the skin, and a year later cutaneous ulceration was noted; five years after infection the lung trouble was first noticed. The left lower lobe was affected with a circumscribed infiltration, the symptoms being cough and shivering. The dulness to percussion had not disappeared after a period of eighteen months' good general health, at the end of which the patient began to spit blood. This was soon followed by an increase in the size of the infiltrated area. For six days the expectoration consisted of chocolate-brown lumps; later, muco-purulent sputa were brought up. The pulse was 90; the breathing 26 to 32 per minute; but there was no fever. The physical signs underwent no appreciable change; there were dulness and pectoriloquy with some râles. The sputa were hardened in alcohol, and had become tough and membranous—some, nevertheless, were lighter than water. The microscope revealed a fibrillated stroma, with finely granular *débris*, old and young cells and nuclei, here irregularly scattered, there arranged in groups. No pulmonary tissue or vessels were detected. Some sputa were sent to Lancereaux, who also regarded the microscopic elements as of a gummatous nature.—*Medical Times and Gazette*, December 9, 1882.

Hypodermic Injections of Blood in Gastric Ulcer.—Prof. Bernutz (*Gaz. des Hôp.*, 64, 1882) has successfully treated two patients suffering from simple gastric ulcer with subcutaneous injections of blood. They were both much reduced, owing to incessant vomiting, everything swallowed being at once rejected. The blood, taken from the femoral artery of a large dog, was received in a warm vessel, and at once injected by means of a warmed Dieulafoy syringe. In the first case the blood was promptly absorbed, and sufficed to keep up the strength for two days. As the patient grew strong the vomiting ceased, and milk diet was resumed. Gradually the appetite improved and food of all kinds was well borne and digested. Fowl's blood was once tried, but its good effects seemed less lasting. The second case was similar, but the patient here was even farther gone through simple inanition. Here the first injection was not absorbed, and a phlegmonous inflammation started from the injection wound and spread over the arm. The gastric difficulties seemed however to decline as the inflammation of the arm advanced. The obstinate vomiting ceased, and with it the gastric pain; so that the patient was presently able to enjoy the ordinary hospital diet. In this instance the blood could have little if any nutritive value, as it was not absorbed. Prof. Bernutz is inclined to think the severe local inflammation in the arm may have acted beneficially in some reflex way on the gastric lesion.—*Practitioner*, December, 1882.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

PHILADELPHIA, PA.

SATURDAY, JANUARY 6, 1883.

THE TREATMENT OF SYMPTOMS INDICATING DANGER IN THE ANÆSTHETIC STATE.

THE anæsthetic state is a condition of danger. It means the suspension of the functions of animal life, the organic functions, especially respiration and circulation, continuing. This primal fact, then, indicates the danger to be provided against. *Cæteris paribus*, chloroform endangers the circulation; ether the respiration. The measures of prevention, as well as the remedies, must be directed accordingly. This law is not absolute in its application. Sometimes chloroform paralyzes the respiratory centre; rarely ether paralyzes the heart. However, so uniformly is the rule applicable, that the injunction in administering chloroform is to watch the pulse, and in giving ether to watch the respiration. Disregarding, for the present, exceptional conditions, the treatment of dangerous symptoms in the anæsthetic state resolves itself into the administration of remedies to prevent or relieve the tendency to cardiac paralysis on the one hand, or to respiratory failure on the other.

The first prophylactic measure on which we insist is the relinquishment of chloroform as the ordinary anæsthetic. We do not deny that there may be special conditions justifying the use of chloroform; it may be necessary when operations are to be performed by the light of an ordinary candle or lamp, since ether vapor forms with atmospheric air an explosive mixture; it may be preferable in obstetric practice, as the anæsthetic agent to assuage the pains of labor, and for various obstetrical operations. With these limitations, the rule of practice should be to employ ether to induce the anæsthetic state under the conditions ordinarily requiring it. The next prophylactic measure consists in the use of morphine subcutaneously—before beginning the inhalation, according to Bernard; after the inhalation has proceeded far enough to induce analgesia, according to Nussbaum. The method of Bernard seems to us the better, because the effect of morphine prevents the sudden failure of the heart sometimes induced by a few whiffs of chloroform vapor, facilitates the inhalation by lessening the irritability of the air-passages, and diminishes or prevents the stage of tetanic rigidity, with its stertorous breathing and cyanosis. We do not pretend to affirm that this method of "mixed anæsthesia," as it has been entitled, has received the unanimous assent of surgeons; but our belief is that the experience thus far accumulated is largely in favor of its utility, and we have the high authority of Dr. J. C. Reeve in its support.

To avoid accident, it is in the highest degree important to ascertain the condition of the subject to be anæsthetized. The habits of life, the absence of cerebral, of pulmonary, and of cardiac diseases of a nature experience has proved to contra-indicate the use of anæsthetic agents, should be ascertained before beginning the inhalation. This survey and scrutiny of the patient should not be limited to a casual examination of the organs supposed to be concerned—it is usually satisfied by a superficial examination of the chest; but it should be made a thorough investigation of the life history in its pathological aspects, as well as a minute study of the somatic state at the time.

We have already, in our comments on fatal cases, alluded to the faults of administration which have been responsible in a large degree for the accidents. It would be a waste of our space and of our readers' patience to reiterate those points already set forth with sufficient particularity in respect to the mode in which anæsthetic vapors should be inhaled. The treatment of the danger-symptoms may, however, require a further exposition of our views. As these danger-symptoms are divisible into causes of cardiac paralysis and causes of respiratory failure, we have thus a natural classification for the arrangement of the data. The quickest mode of dying is by arrest of the heart's action. Unfortunately, in a large proportion of cases, the heart is incapable of further action when its embarrassment is ascertained, and hence the wisest measures may be futile. We must, in advance of the expression of our own views, protest against a practice which has become too common: namely, the subcutaneous injection of digitalis. If this agent acts rapidly enough to affect the circulation, the result must be disastrous, since it induces such a rise in the arterial tension as to im-

pose additional work on the heart. A remedy acting in the opposite way—to lower the tension at the periphery and thus diminish the resistance to the propelling power of the heart—seems, *a priori*, to be more suitable, and experience confirms this theoretical view. The subcutaneous injection of amyl nitrite has appeared to be of immense service in some cases of threatened cardiac paralysis. From three to five minims are injected beneath the skin at any point, or, if respiration is going on, the effect can be more speedily procured by inhalation. The good effect consists in the diminution of the peripheral pressure, which permits the heart to distribute the blood more easily, and thus to supply more quickly and fully the centres of organic life.

The intravenous injection of ammonia is, also, a promising expedient to arouse the heart. The Australian experience with this practice has abundantly proved that the intravenous implantation of one drachm of aqua ammoniæ, diluted with two drachms of water, is perfectly safe, and a powerful cardiac stimulant. The time for its administration is when the action of the heart has become weak and fluttering and a stoppage imminent. Any convenient vein may be selected; the needle of the hypodermatic syringe is thrust directly into it, and the ammoniacal solution is promptly, but without violence, delivered in the blood stream. A half-drachm should be administered at a time, the repetition of it being governed by the effect.

Another agent having decided power to increase the heart's movements is atropine. Although this may not act as speedily as the intravenous injection of ammonia, it is next in respect to promptness of effect. As a rule, however, it is preferable to administer atropine in combination with morphine before beginning the inhalation of the anæsthetic vapor.

Acupuncture and electro-puncture of the heart have also been suggested, and, indeed, used in some cases, but after a careful survey of the whole ground we are forced to the conclusion that these expedients are rather injurious than beneficial. To puncture the heart—especially to send a faradic current through a needle inserted into its substance—must cause a more or less severe shock. All the world knows the effect of shock on the cardiac movements. Can such manipulation fail to depress the heart's functions? Again, the exact position of the perforating needle should be known, since the inhibiting ganglia may be stimulated rather than the motor. To stimulate the former, is to stop a heart which is in action.

When the failure is respiratory—the chief danger in ether inhalation—the respiratory centre should be supplied with blood as quickly as possible. The method of Nélaton, of inversion of the body, accomplishes this. The tongue falling back in the throat forces down the epiglottis, and the violent inspiratory efforts increase the danger by converting the epiglottis into a valve. Hence, to draw out the tongue strongly is a most necessary expedient for freeing the entrance to the larynx. It accomplishes more. The strong traction on the basal attachments of the tongue exerts a reflex effect on the respiratory centre, and this, according to some, is the chief use of the practice. Faradization of the chest muscles, inhalation of ammonia, irritation of the Schneiderian mucous membrane by a bit of paper dipped in aqua ammoniæ, are the means resorted to for reflex stimulation of the respiratory centre. Dashing cold water over the chest exposed to cold air from an open window is one of those doubtful measures often resorted to in the excitement of the moment, but which, of little use at the time, is apt to be followed by bronchitis or pneumonia.

Certain stimulants of the respiratory centre may be employed subcutaneously. These are atropine and strychnine—the former generally preferable, because more prompt. The alcoholic stimulants so often used hypodermatically are of doubtful utility, although apparently beneficial in some cases. As ether and chloroform are derivatives of alcohol and act in a similar manner on the centres of organic life, to administer the latter as a remedy for depression or arrest of function produced by the former seems to be an irrational procedure, and may, indeed, in any doubtful case, determine the result unfavorably, but the counter-irritant effect of the injection may, however, possibly exercise a favorable influence.

SYMMETRICAL GANGRENE OF THE EXTREMITIES, WITH ALBUMINURIA.

AT a recent meeting, Oct. 27th, of the Medical Society of Hospitals in Paris, M. ROQUES reported a case of symmetrical gangrene of the hands and feet, accompanied by albuminuria, in a woman who was also the subject of intense congestion of the right lung and dyspnœa. To these symptoms were added enlarged liver, irregular and strong cardiac impulse, and dimness of vision, but there was no retinitis albuminurica. For three months she had at times experienced a decided sensation of coldness of the surface of the hands, the fingers becoming pale and apparently dead; three days before admission the same phenomena appeared on the surface of the great toe of the right foot, and four days later on the same toe of the left foot. The skin of these toes presented a purplish hue, which disappeared upon pressure, returning slowly upon its removal; they were cold, painful, and deficient in tactile sense. There were also on the dorsal surface of the feet, and on the external surface of

the leg and thigh, irregularly mottled patches, but no trace of œdema. These lesions were absolutely symmetrical but more marked upon the left side. There was an evident but feeble pulsation in the two pedal arteries. In the upper extremities the same conditions were present: all the fingers, except the thumb, were cold, insensitive, and purple; the right ear was dry and shrivelled; the hands and arms were mottled with livid patches. Some days later the little finger of the right hand and the right great toe became entirely sphacelated. At times the heat returned in the extremities, the livid patches disappeared and the sensibility returned, but a fresh attack of the "local asphyxia" repeated the same phenomena. The dyspnœa and irregularity of the heart increased, and she died twenty-eight days after admission. At the autopsy there were found splenization of the right lung, hypertrophy of the heart, a circle of soft villous vegetations on the aortic valves, but no mitral disease. There was a nutmeg liver, the spleen was healthy, and the kidneys were the seat of marked interstitial nephritis. *There was no atheroma of the pedal or radial arteries.*

The question naturally arises, Can there be any causal relation between these two conditions? Raynaud and Débove have noted albuminuria in several cases of symmetrical gangrene, and there have been observed in Bright's disease certain phenomena which are apparently due to vaso-motor influences, such as the localized œdemas which come and go suddenly and seem to be associated sometimes with traumatic nephritis of one kidney; such also are the phenomena of the "dead finger" and varied forms of pruritus recently noted by Dieulafoy. M. Roques is inclined to believe that the union of these two conditions is a coincidence, but admits that further observations are required. Such would indeed seem to be the only inference which can be drawn.

DR. M. WEISS of Prague, has recently published in the *Wiener Klinik*, a very interesting monograph on symmetrical gangrene, in which he collates seventeen cases, including a very carefully studied one of his own. The first of these cases was recorded in 1729, the last in 1882, so that it will be seen to be a very rare disease. It is defined by him as an affection of the central nervous system, characterized clinically by numerous vaso-motor, trophic, motor, sensory, and special sense derangements, while it receives its distinctive stamp from a symmetrically occurring gangrene of parts of the hands and feet (phalanges), and more seldom of other parts of the body. The term "symmetrical gangrene" was originally applied to the condition by Raynaud, who first described it in 1862; and although from the fact that the term recognizes but a single, yet the most striking, symptom, Weiss considers the title "neurotic gangrene" more appropriate, he retains Raynaud's title.

That the case described by M. Roques is one which may be properly included in the category of symmetrical gangrene we are by no means certain. In the first place, the disease seems not to have been usually fatal as in the present instance, but is paroxysmal, the paroxysms beginning with pain, which is often extreme, in circumscribed spots on the affected extremities. This is succeeded by a gangrene which may be superficial or may involve an entire phalanx; the separation of the slough being succeeded by a repair which is proportional to the destruction. Along with this are numerous other local and general derangements which we have no space to detail. Such a paroxysm is succeeded by others at intervals of a month or more, in some instances coinciding with the menstrual period. The immediate cause of the gangrene must, however, be the same in each instance. The symmetrical character of the process excludes the usual local causes of gangrene, such as obliteration or obstruction of afferent vessels, embolism, mechanical, chemical or thermic agents, etc., and there was no atheroma or ergotism; so that there remains only the effect of a weak heart or some one of the trophic influences which can alone account for symmetrical gangrene; and a heart so feeble as to be the cause of symmetrical gangrene in the extremities is scarcely likely to be present in a woman of 41, even if there be aortic obstruction, as may have been the case here. From such trophic influences must also be excluded vaso-motor spasm, because striking as are the functional results of such arterial contraction in experiments on animals, gangrene has never been produced by irritation or stimulus of vaso-constrictor nerves. They must, therefore, be trophic in the strictest sense of the term. Now no such slowly operating trophic influences have ever been known to exist in interstitial nephritis, or in any form of Bright's disease, and we, therefore, conclude that the association of the two conditions is a purely accidental one.

FETID BRONCHITIS, AND ITS TREATMENT BY THE HYPOSULPHITE OF SODIUM.

UNDER the above title, DR. E. LANCEREAUX, in a recent issue of the *Bulletin de Thérapeutique*, treats of fetid bronchitis chiefly from the therapeutical point of view. The real causes of the malady are not fully understood. Dilatation of the bronchial tubes, and accumulation in the depôts thus formed, of the muco-purulent secretion, is probably the first step, decomposition of the muco-pus under the agency of atmospherical germs being then produced. Butyric and valerianic acids are amongst the odorous substances thus formed. Dr. Lancereaux regards this a most fatal malady—an opinion

in which all experienced physicians will concur. It is well known that the lesions are not limited to the bronchi, but extend to the peri-bronchial connective tissue, and to the pulmonary parenchyma ultimately. So fatal is it, that all of the subjects of this disease admitted to *la Pitiê*, died, when treated in the orthodox way, with alcohol and quinine. Far different has been the result, when treated with hyposulphite of sodium. His observations are based on twenty cases—fourteen treated by the old method—which proved fatal, and six treated by the hyposulphite, all of which recovered. He gives the details of the latter.

The mode of administering the remedy is very simple. It consists in giving 4 to 5 grammes (about 62 to 80 grains) in an ordinary solution daily for a month to six weeks, after which the amount used will be determined by the conditions present. The digestive functions are improved rather than embarrassed, and no derangements of any kind are to be referred to its action. It does not produce the desired result immediately, but several days, often a week, will elapse before the curative results are manifest. The first effect of a therapeutical kind observed is a diminution in the odor of the sweat and of the muco-pus brought up from the bronchi. The amount of the secretion diminishes, and its character changes, becoming more distinctly mucous and viscid. Following this lessening of the expectoration and disappearance of its fetidity, the appetite improves and the weight lost by the continuance of the disease is regained, and the bodily forces are restored to their wonted activity. The time required to effect these marvellous results varies somewhat, but the rule appears to be that in from six weeks to three months the changes in the condition of these subjects, above described, will have taken place. Sometimes, it is true, in the course of the treatment, there may be a return of the fetidity, but it will be brief, and the evil odor will gradually disappear and permanently.

How is the cure of these cases effected? is the inquiry made by Dr. Lancereaux. There can be, at present, no correct answer made to this question. To offer a satisfactory solution of the problem, it will be necessary to know what changes the alkaline hyposulphites undergo in the system, and the mode of their elimination. To effect the cure of such a condition, they must act, not only on the process of decomposition in the muco-pus, but on the organic changes to which the pathological exudate owes its origin. It is, however, of comparatively inferior consequence how the medicament acts.

Does it cure? If so, we are put in possession of a most valuable agent, able to cure a malady hitherto beyond the resources of art. We need now further clinical experience. If Dr. Lancereaux's observations are confirmed by others, if new facts of corresponding significance are brought forward, we may safely postpone the consideration of the *modus operandi* to a more convenient season.

IN the December number of the Brooklyn *Annals of Anatomy and Surgery* the editors indulge in some personal reflections not inappropriate to the successful close of the third year of its publication.

The *Annals* began as a modest record of the work of the young but vigorous Anatomical and Surgical Society of Brooklyn, whose example we commend most heartily to other less enterprising communities. But it has now, as it were, cut the umbilical cord, and becomes an entirely independent journal, for which the editors alone will be responsible.

The announcement for 1883 is very attractive in the list of names of those from whom papers are expected, and Dr. Geo. J. Fisher, we are glad to see, will continue his delightful and scholarly sketches of the "old masters." We notice with pleasure, also, that the proceedings of the New York Surgical Society will appear in the *Annals* as well as in THE NEWS. This cosmopolitan publication of their proceedings by the various medical societies, we are happy to observe, is becoming very common. Certainly it bears good fruit in the stimulus to writers, who find that their papers appear promptly, and that their circle of readers is increased tenfold. By the ancient method they quietly slept for weeks or months till the "Proceedings" appeared in the glory of a bound volume—which, in most instances, was immediately put upon the shelf—or were seen solely by the readers of the local journal that had the exclusive right to their publication.

THE New York State Board of Health has officially declared: "That the use of privy-vaults, privy-pits, and cesspools, is seriously affecting the public health;" and further, "That all excreta should be removed from the neighborhood of human dwellings, instead of being stored up near them in pits, vaults, or pools, to poison the water, earth, and air." In some European cities the abandonment of the old cesspool system has already been accomplished, and in others the measure is being seriously contemplated. A Commission of Inquiry is now endeavoring to solve the problem of providing Paris with a system of sewerage which shall take the place of the older plan, in which the excreta are detained in permanent cesspools, generally under the houses, and the more modern system in which movable reservoirs are made use of for catching the solids while the liquids escape into the sewer. Dr. E. Vallin, Professor of Hygiene at Val de Grâce, says that every one is agreed, at least in principle, upon one point,

namely, that permanent cesspools, as forming a structural portion of dwelling-houses, should be superseded. The question upon which there is still a difference of opinion, relates to the choice in the modifications of the water-carriage system which is to form the substitute. In this country this much-needed reform is likewise being agitated, and its accomplishment is only a question of time.

PROFS. SCHÜTZ and LOEFFLER have just succeeded, we learn from the *Deutsche Medicinische Wochenschrift* for Dec. 16, in isolating a micro-organism in subjects affected with farcy; they have succeeded in growing several generations in culture fluids, and in transmitting the disease by inoculation to healthy horses. The details of this discovery, which has just been made in the *Kaiserlich Deutsche Gesundheits Amt*, in Berlin, have not yet been published.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting December 12, 1882.

THE PRESIDENT, DR. T. M. MARKOE, IN THE CHAIR.

EMPYEMA; PERFORATION OF THE BRONCHI AND DIAPHRAGM; RECOVERY.

DR. F. LANGE presented a male patient, 19 years of age, with the following history. He was a healthy member of a healthy family, and a student. After repeated attacks of gastric disturbance in the summer of 1881, he was taken, September 2, with severe gastro-intestinal catarrh, which became so obstinate that he was confined to the bed from the eighth to the fifteenth of that month, and was under the care of Dr. Henkel. He had only a moderate fever, but gradually lost flesh and strength. Very soon after this, a deep-seated abscess developed in the inner aspect of the arm, and it seemed to take its origin in the muscular substance of the biceps. Dr. Lange opened the abscess in the presence of Dr. Henkel on the 26th of September, and the wound healed without further trouble, but the patient did not rally entirely. On the 7th of October he was taken quite suddenly with severe pain in the lower part of the thorax on the right side, and went to bed again. Very soon afterwards the physical signs of pleuritic effusion became apparent, and, in a comparatively short time, the level of the fluid was as high as the middle of the scapula. The presence of crepitus and near bronchial breathing above the line of dulness made it probable that the inflammatory process, to some extent, affected the lung tissue. The area of dulness was considerably smaller in the axillary region than behind, and was almost absent in front. There was continued fever with exacerbations at night, and the patient had no appetite and lost flesh and strength rapidly.

On the night of the 19th of October, perforation of the bronchi occurred and large quantities of pus were expectorated. On the following day the patient felt much relieved, although he was very exhausted. Dr. Henkel then found the physical signs of pyo-pneumothorax, especially the metallic sounds. The patient did not rally as had been expected, the fever did not cease, and the debility increased. It was impossible to make a thorough examination of the chest on account of the extreme weakness of the patient, but it was ascertained that the respiratory murmur could be heard from above, downwards to the fourth intercostal space in front, and to the middle of the scapula behind. At the latter point the breathing was amphoric in character. The level of the fluid was considerably lower down; succussion sound could be obtained distinctly. Dr. Lange saw the patient again in consultation, on the 23d of October, and from the history of the case felt certain that there was pus in the pleural cavity, but aspiration gave a negative result. Puncture was made at four different places, but only a few drops of blood mixed with air were obtained. Assuming that the collection of pus might be near the centre of the lung, deep punctures were made. Dr. Lange had already determined to desist from further surgical interference, when he discovered at the lowest part of the thorax, toward the lumbar region and against the lateral border of the sacro-lumbalis, air under his fingers on pressure upon the deep tissues. He punctured at that point, found pus, and then opened the cavity by a free incision. There was an abscess below the diaphragm, along the under surface of which the finger could be passed after being introduced through the incision. Apparently the empyema had perforated the diaphragm. The expectoration very soon ceased, and the patient made a rapid recovery. With the exception of slight retraction of the lower and front part of the right side of the chest, with diminished respiratory murmur in that region, there was scarcely any difference to be noticed when the two sides were compared. Dr. Lange thought that the point at which perforation of the diaphragm occurred was possibly at the gap between the vertebral and costal part of that muscle, which is sometimes very large. He was unable to make out whether the abscess was intra- or extra-peritoneal, but thought it was probably the latter. The kidney, on account of swelling and infiltration of tissues around it, could not be felt distinctly. The outline of the liver was recognizable by palpation. Last summer, Dr. Lange was shown, at Professor Thiersch's clinic in Leipzig, a patient who had sought admission because of a freely discharging fistula over the anterior aspect of the right femur. The etiology of the abscess became apparent when purulent expectoration began simultaneously with the cessation of discharge of pus from the fistula. The patient stated that this had occurred several times, and examination of the chest upon the right side gave evidence of an encapsulated empyema, for which thoracentesis with resection of a rib was performed. Recovery followed rapidly. Dr. Lange was inclined to believe, although unable to prove it, that there was a causal relation between the abscess in the biceps and the empyema, the latter being the result of an embolic process. In reply to a question, he stated that the largest collection of pus was above the diaphragm, probably a pint being in the cavity below it.

THE PRESIDENT remarked that, in a similar case, he found the accumulation of pus much larger below than above the diaphragm, pressing into and upon the abdominal cavity.

DR. POST asked which occurs most frequently, abscess originating in the thoracic cavity with perforation downwards, or abscess beginning in or near the liver with perforation upwards?

DR. BRIDDON replied that he thought perforation upwards occurred most frequently. In a similar case admitted to the Presbyterian Hospital, probably a year ago, the cavity of the chest had been aspirated and a large quantity of pus removed. There was dulness on percussion up to the spine of the scapula, behind and to a line nearly upon the same level in the

axillary region, and there was a large area of dulness in front. There was also a marked bulging in the neighborhood of the liver, which was mapped out quite accurately by the area occupied by an enlarged liver. Fluctuation was detected by palpation over this large swelling, and the sensation could be distinctly felt carried through to the lumbar region. Dr. McBride, one of the visiting physicians, examined the patient, and regarded it as a case of perinephritic abscess, which had pressed the diaphragm upwards, developing a condition simulating empyema. Dr. Briddon attempted to aspirate from behind, and passed the needle three or four inches deep without obtaining anything. He then aspirated in front and removed a large quantity of bloody serum. There was no appearance of pus to the naked eye in the fluid, but the microscope revealed a certain number of pus corpuscles. He aspirated several times subsequently, and obtained the same kind of fluid, but never at any time fluid which had the usual appearance of pus. The patient subsequently came under Dr. L. A. Stimson's care, who made an incision behind into the cavity of the chest, and gave exit to a large quantity of pus. The patient subsequently expectorated large quantities of pus, and it was noticed that when the expectoration was obstructed or defi ient in quantity, that the subdiaphragmatic swelling would increase in size. At the time he had some doubt as to whether the abscess was sub-diaphragmatic or not.

DR. YALE added an item in the clinical history which filled up an interspace between the service of Dr. Briddon and that of Dr. Stimson. He saw the patient soon after Dr. Briddon first saw him. The man came into the hospital one afternoon greatly oppressed in breathing, and Dr. Yale aspirated his thorax, and drew away a little more than ten pints of pus. This was followed by the operation already alluded to, and performed by Dr. Stimson. As he recollected, Dr. Stimson was not quite sure where the cavity was even after the operation had been performed. Dr. Yale thought, however, that the opinion of the majority of the visiting surgeons was that the case was one of perinephritic abscess which had worked its way upwards.

DR. LANGE then read a paper entitled

ANATOMICAL AND CLINICAL CONSIDERATIONS CONCERNING THE RETRO-PERITONEAL SPACE IN THE REGION OF THE LAST RIB.

DR. HALSTED asked Dr. Lange if he believed that the lower limit of the pleural cavity was lower than that which had been given by Dr. Hull.

DR. LANGE replied that in some cases it was much lower, and in other cases it was higher. On the average, however, he should say that it was lower.

DR. WEIR remarked that it was not often he had the opportunity of testing upon the living subject the accuracy of the remarks made by Dr. Lange. Recently, however, he had had the opportunity of cutting down upon the tissues in that region which were tolerably normal. The operation was one for making fast or anchoring a movable kidney. In that instance he found that the kidney fat, in a patient only moderately stout, was, on being incised, or torn through, capable of being readily separated, and in that manner enabling him to expose the kidney, and by traction on the investing tissue to raise the organ towards the surface quite satisfactorily. However, even in this case of movable kidney, there was considerable difficulty in reaching and appreciating the pelvis of the organ. He put his finger in for the purpose of education, because one or two years ago he had placed upon record the view that in those cases in which there has been for years previous signs of obstruction of one ureter, and then signs of obstruction in the other ureter developed, one might proceed to a lumbar incision, and by opening the pelvis of the kidney or ureter, above the site of obstruction, with a view to saving the patient's life; an operation which had recently, he said, been performed by Bardenheur with success.

DR. LANGE remarked that the position of the kidney could be changed considerably in a lateral direction. He had also found that if the lower part of the kidney was pulled upwards and laterally, the entire organ would be pulled not only laterally, but at the same time its lower edge would be upwards and made to perform a sort of torsion.

DR. BRIDDON asked Dr. Lange what incision he would make in nephrectomy.

DR. LANGE replied that he would make an incision extending from the apex of the last rib, if that could be felt; in other words, make Czerny's incision. If the rib could not be felt, he would take the line of the sacro-lumbalis, or the quadratus lumborum muscle. In reply to a question by Dr. Halstead, he remarked that counting from the spines could hardly be depended upon as giving proper directions for making the incision.

VESICAL CALCULUS.

DR. H. B. SANDS presented five small vesical calculi, the largest being one-half of an inch and the smallest about one-third of an inch in diameter, which he had removed thirteen days previously by lateral lithotomy. The interest of the case consisted in the fact that this operation had to be performed in the place of the crushing operation, which would have naturally been selected for the removal of stones of this size. The patient was a man fifty-seven years of age, who had suffered from symptoms of stone for three years. He was seen by Dr. Van Buren between two and three years ago, when it was discovered that his prostate gland was unusually large. On that occasion a sound was introduced into the bladder, but a stone was not detected. Some doubt seemed to have been felt by Dr. Van Buren as to whether or not a stone was present, for he told the patient that he wished him to return for another examination. Considerable irritation following this exploration, the patient did not return to have it repeated. He continued to suffer more or less from cystitis and irritable bladder, and about two months previous to the time when Dr. Sands first saw him, his symptoms became very severe. The patient suffered from spasmodic contraction of the bladder accompanied with great pain. Owing to prostatic hypertrophy, he had for nearly three months been unable to evacuate the bladder except by means of a catheter, which, however, was readily introduced. Previous to Dr. Sands' visit, the patient had been seen by Dr. Doughty, who had sounded him upon three occasions. At the first examination a calculus was detected, but it was observed that the sound, a Thompson's searcher, could not be moved as freely as usual in the bladder. The second and third examinations failed to detect any stone. When Dr. Sands visited the patient he administered ether, and made a careful exploration of the bladder and rectum. An instrument with a large curve passed readily into the bladder, but one having the curve of Thompson's sound, could not be made to enter. This fact had been previously noticed by Dr. Doughty. The prostate when examined by the rectum, was found to be exceedingly large. The urethra was measured, and was ascertained to be nine and a half or ten inches in length. When the Thompson's searcher was introduced it would pass the entire length of the instrument, which was nine and a half inches, and still its point did not enter the bladder.

The instrument seemed to be arrested by some bar of prostatic tissue. Introducing the instrument as far as it would go, Dr. Sands endeavored to move it, but the point remained nearly stationary, apparently grating against a rough surface of prostatic tissue. A stone was detected situated upon the patient's left side, and apparently just at the neck.

DR. SANDS decided to perform lateral lithotomy, and thirteen days ago he removed the five calculi presented; four were whole, and the fifth one was in fragments. Each calculus consisted of a uric acid nucleus, covered with concentric layers of phosphates. The patient, a few hours after the operation, had a chill and began to suffer from retention of urine. Dr. J. C. Hutchison, who had assisted at the operation, was called and succeeded in introducing an instrument into the bladder through the penis. Using this as a guide, he introduced a Nélaton's catheter through the perineal wound into the bladder and tied it in position. This gave the patient complete relief, and through the instrument remaining in the wound the urine was allowed to trickle for eleven days. About two days after the catheter was introduced it was noticed that the point of the instrument tended to escape from the bladder into the deeper part of the urethra; believing that it would be better to let the instrument lie there in the wound than in the bladder, thus preventing the liability to incrustation, it was allowed to do so, and every two or three hours it was introduced far enough to allow the urine to escape. Two days ago the catheter was removed from the wound, and has since been introduced through the penis, whenever necessary.

DR. SANDS regarded the case as interesting in two respects. In the first place, it afforded an illustration of the fact that even when the stone was small all cases of vesical calculi could not be treated by the crushing operation. A similar case came under his observation about six weeks ago, in which he was obliged to perform lithotomy and remove a stone, not larger than an almond, because he failed after repeated attempts to seize the calculus with the lithotrite. In this case there was no difficulty in inserting the instrument into the bladder, but it could not be made to seize the stone, which lay in a pouch behind the prostate. This cavity, which was apparently bounded behind by a muscular band extending between the orifices of the ureters formed a cavity which was not more than one inch in its longest diameter, large enough to contain a stone, but not large enough to allow the blades of the lithotrite to open and seize it.

The second point of interest was the occurrence of retention after the operation of lateral lithotomy, in which a pretty free incision was made. This was the second case in which this rare complication had followed lateral lithotomy in his practice. Usually the urine flows freely from the wound, and catheterism is not necessary. In the other case, as in this, the prostate gland was considerably enlarged, and he inferred from his experience that when lateral lithotomy is performed in such circumstances, especially where the bladder is weak, the proper course would be, after extraction of the stone, to wash out the bladder, insert a flexible catheter and allow it to remain in position. In addition, he believed it to be advisable to allow the point of the instrument to recede from within the bladder and subsequently to push it forward at regular intervals to permit the escape of the urine.

DR. POST referred to a case in which he assisted the late Dr. Buck in the performance of lateral lithotomy, and retention followed the operation. On introducing the catheter the next day, a large quantity of urine was drawn off. In that instance a fatal result occurred. There had not been retention during the operation.

DR. WEIR referred to a case in which Dr. Buck operated, and in which retention followed the operation, but in that instance another calculus was found in the bladder.

DR. POST remarked that Mr. Liston, of Edinburgh, once remarked to him that he was in the habit of introducing a catheter, and allowing it to remain after performing lithotomy, because he believed that the safety of the patient was promoted by it.

PTOSIS WITHOUT STRABISMUS, AND AMAUROSIS WITHOUT A DILATED OR SENSITIVE PUPIL.

DR. POST narrated a case as follows: A boy, fifteen years of age, was brought to his clinic last Saturday, who had been in the enjoyment of fair health, except that he had suffered from headache during the last two years to a considerable extent. About five days before he was brought to Dr. Post, the patient was suddenly attacked with ptosis of one eye, and there was almost absolute loss of vision attending it. There was bare perception of light. There was no strabismus, and the pupils of the two eyes corresponded with each other, and both were sensitive to light. The occurrence of ptosis without strabismus, and amaurosis without dilatation or sensitiveness of the pupil, seemed to him to be unusual.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 21, 1882.

THE PRESIDENT, FORDYCE BARKER, M.D., LL.D., IN THE CHAIR.

AFTER the report of the Secretary, the CORRESPONDING SECRETARY reported the death of Sir James Alderson, who died at an advanced age in London, in December of the present year; also that of Sir Thomas Watson, Fellow of the Royal College of Surgeons, who died in London, December 11, 1882. He was best known to the American profession through his lectures on the practice of medicine.

The STATISTICAL SECRETARY reported the death of Michael Hagan, a Fellow of the Academy, who died at the age of sixty-seven, on the 8th of December,

The SECRETARY read a letter from the Secretary of the Northwestern Medical and Surgical Society of New York, enclosing a check for one hundred dollars as a gift to the Journal Department of the Academy. Upon motion of Dr. White, the Academy extended to the above Society a vote of thanks for its kind and generous donation.

The next business was the presentation of a marble BUST OF THE LATE PROF. JAMES P. WHITE, OF BUFFALO, by Dr. Austin Flint, Sr. This was the gift of the late Prof White's son, Mr. James P. White. The sculptor was Mr. J. G. Mitchell, of Rochester.

DR. FLINT moved that the Academy extend a vote of thanks to James P. White for his generosity in presenting to it a marble bust of his father.

THE PRESIDENT called upon Dr. Thomas to second the motion, who responded in a few graceful and well-timed remarks, saying that he thought it eminently proper that the bust of our late honored Fellow should have a place in the hall of the Academy opposite that of the greatest of living ovariotomists, Mr. Spencer Wells, of London.

The motion was unanimously carried.

The next business was the scientific work of the evening.

DR. T. GAILLARD THOMAS presented

A CONTRIBUTION TO THE SUBJECT OF THE REMOVAL OF THE UTERINE APPENDAGES (TAIT'S OPERATION) FOR PROLONGED MENSTRUAL TROUBLES WITH RECURRENT PELVIC INFLAMMATIONS, WITH SPECIMENS.

In the issue of the *British Medical Journal* for July 29, 1882, appeared a remarkable essay by Mr. Law-

son Tait, of Birmingham, England, enunciating views entirely at variance with those heretofore held by the medical profession, advocating pathological tenets which were altogether new, and recommending a plan of treatment which is at once original and bold. This article was entitled, "Remarks on the Diagnosis and Treatment of Chronic Inflammation of the Ovary."

Dr. Thomas referred to the article at some length, first, because his own paper was based upon its suggestions; second, because he felt sure that the positions which it assumed would interest the Fellows of the Academy, even if they denied their validity; and third, because he himself was convinced that this bold and original surgeon had advanced views which were destined to open a new field for gynecological surgery in the future, and to exert upon this department of medicine an enduring influence.

While the speaker did not feel warranted from his own experience and observations in accepting all the conclusions of Mr. Tait, he believed that there was a sufficient amount of truth in some of them to make the essay above referred to one of the most valuable that this decade had produced for the gynecologist.

Since that period, which constituted so remarkable an era in the history of gynecology, when Henry Bennet, Simpson, and Marion Sims brought their eminent labors to bear upon this department of medicine, until the present time, a vast deal of attention had been directed to the uterus, vagina, the uterine ligaments, and the pelvic peritoneum, and the areolar tissue, while the diseases of the ovaries and Fallopian tubes have been left enveloped in a cloud of ignorance and uncertainty which few have endeavored to penetrate and dispel. Tilt, of London, the firm, persistent, and able advocate of the claims of ovarian pathology, has, during this time, stood almost alone, steadily and consistently enunciating views with which few sympathize and still fewer endeavor to sustain. At the present time, however, it seemed that a wholesome revolution was occurring in this respect; that reflective men, devoted to gynecology, were now recognizing the fact that a very large proportion of cases of menstrual disorder, pelvic neuralgia, and difficult locomotion, which were formerly attributed to the uterus, its ligaments, or the pelvic areolar tissue, are entirely due to ovarian disease, and that hundreds of cases in which this devoted organ was cut, cauterized, and leeched, had the same pathological origin.

Mr. Tait assumed: *First*, that the view formerly held that laparotomy operations should be postponed until absolute risk to the life of the patient rendered them necessary, should now be abandoned; and that in the hands of an expert they are at present so free from danger as to be practicable even when life is not jeopardized. *Second*, that the usually accepted doctrine of the dependence of menstruation upon the ovarium is wholly erroneous. *Third*, that the ovaries have nothing whatever to do with menstruation, and that this phenomenon is dependent upon the Fallopian tubes. *Fourth*, that the many cases of abnormal menstruation are justifiably treated, and are relievable in no other way than by extirpation of the ovaries and tubes. *Fifth*, that in chronic ovarian disease the tubes are invariably involved, and that in most cases it is the tubes which are chiefly at fault. *Sixth*, that the mortality in his last thirty-five operations having been only one, even this slight loss of life is susceptible of diminution in the future. *Seventh*, that many of those cases heretofore regarded as instances of menstrual or recurrent pelvic peritonitis or cellulitis are really due to tubal dropsy and ovarian disease; an occasional discharge of the purulent accumulation of the former giving rise to slight and passing attacks of these affections.

Dr. Thomas stated that the removal of the uterine appendages, as it concerned his remarks, had nothing whatever to do with the subject of ovariotomy. The latter operation was resorted to for the removal of large and increasing tumors, which, if not removed, almost invariably destroy life within a few years. The former was performed for severe menstrual disorders and nervous troubles having their origin in the uterine annexæ, which, while they do not jeopardize life, render it utterly miserable and intolerable.

Dr. Thomas's contribution was merely a report of four cases in which very grave menstrual trouble accompanied by all the symptoms of recurrent pelvic peritonitis and cellulitis were found due to tubal dropsy existing coincidentally with chronic ovaritis, exactly as Mr. Tait had described it.

Case I. was a colored woman, 30 years of age, who commenced to menstruate at fourteen; she had been married nine years, and was the mother of one child, eight years old. Her menstruation was perfectly normal up to the period of weaning her child, eighteen months after delivery. At that time she was taken with very sudden symptoms resembling those of cellulitis or peritonitis, accompanied with slight bloody discharges from the vagina. She was confined to bed for about a week, since which time she has been a confirmed invalid, her menstrual periods being painful, scanty, and irregular. Upon making an incision in the mesial line and passing two fingers into the iliac fossa, Dr. Thomas drew up an ovary about as large as an English walnut, distended by a multitude of small cysts, and the Fallopian tube resembling closely in size an ordinary sausage, and giving to the touch very much the feeling of a loop of intestine. Tube, ovary, and ovarian ligament were ligated with an aseptic banjo string and removed; the same condition was found to exist on the other side, and the same procedure was adopted. The operation was performed under the strictest antiseptic precautions, except that the spray was not used during the operation. On the thirteenth day after the operation the patient was sitting up in bed, having recovered completely, without a bad symptom. The time of one menstrual period had passed, and as yet no sanguineous discharge had occurred.

Case II. was a lady 25 years of age, who had been married three years, and was the mother of one child, eighteen months old. Her menstrual periods began at the age of seventeen, and before her marriage gave her no trouble whatever. Nine months after confinement she was taken with an attack of pelvic inflammation, which seemed to have been unquestionably one of slight cellulitis or peritonitis. Since the birth of her child she had never been well, and suffered from constant pelvic pain, with occasional accessions of inflammation. She menstruated irregularly and painfully, and suffered from leucorrhœa and difficulty of locomotion. At the operation the ovaries were found very slightly diseased, but the tubes were distended by large accumulations of pus. Both ovaries and tubes were removed. The patient recovered without any remarkable rise of either pulse or temperature.

Case III. was that of an unmarried lady aged 22 years, who began to menstruate at fourteen, from which time she had suffered from most dreadful dysmenorrhœa until a year ago. Pain was confined to the menstrual period, and was agonizing for thirty-six or forty-eight hours. Both ovaries and tubes were removed. The ovaries were found filled with small cysts and the membrane lining the tubes inflamed and bathed with pus, which was, however, not confined within them so as to create dropsical enlargement. The patient recovered without unfavorable symptoms.

Case IV. was a maiden lady 27 years of age, who began to menstruate at fourteen. This was accom-

panied with severe pain until two years ago. Her case would have been classed as one of those very common ones of exceedingly severe dysmenorrhœa. At this time she had a short attack of pelvic peritonitis, and had ever since been a most wretched invalid, having become greatly emaciated, suffering constantly, and being almost continually confined to bed.

An operation being decided upon, owing to her low vital condition, an attempt was made to get her into a more favorable condition for the operation. This, however, proved ineffectual after a fair trial, and it was decided to operate at once, which was done on the 11th of the present month. The ovaries were not very much diseased, but they contained a number of small cysts. The Fallopian tubes were dropsical, and throughout their whole extent firmly bound down by false membrane, which had to be torn with considerable force. The operation was tedious and difficult, and at its conclusion no one who witnessed it could avoid making an unfavorable prognosis as to the result. Twenty-four hours afterwards one of those insidious attacks of peritonitis, with low temperature and slight pain, which so often develop after laparotomy, declared itself, and on the sixth day destroyed the patient's life.

The ovaries and tubes that were removed from the first, second, and fourth cases were presented to the Academy, those of the third having accidentally been lost. The tubes were greatly enlarged and characteristic of the condition described by Tait.

Dr. Thomas called attention to the fact that the results from Mr. Tait's oöphorectomy operations had, like those of Keith, Wells, and several other European surgeons from ovariotomy, been exceedingly gratifying. In this country we could present no such glowing accounts of the results of these operations. It was true that surgeons might lull their misgivings to rest by listening to the kindly suggestions of a superior physique on the part of patients, a more advantageous climate, and the concentration of cases in the hands of experts on the other side of the Atlantic, but it was unlike the genius of our land to accept such placebos. He suggested, therefore, that we look the disagreeable truth boldly in the face, and recognize the fact that, so far at least, our European brethren in this field of surgery were for some unknown reason ahead of us. The discrepancy which existed between our statistics today could not be met by argument; it must be abolished by results.

THE PRESIDENT announced that the paper of Dr. Thomas would not be discussed independently.

The next paper was a

COMPARISON BETWEEN GASTRO-ELYTROTOMY (THOMAS'S OPERATION) AND OÖPHORO-HYSTERECTOMY (PORRO'S OPERATION),

by DR. HENRY J. GARRIGUES.

The paper consisted of a critical comparison, from the surgical standpoint, of the two operations, the aim of the author evidently being to make a strong plea in favor of Thomas's operation. He considered that the latter had various advantages over the Porro or the Porro-Müller operation, and argued that it should, at least, be given a fair trial. By operating early, or refusing to operate upon dying subjects, there could be no doubt but that the danger of the operation would be shown to be much less than the present statistics would seem to indicate. Though the Porro operation had an advantage from the standpoint of antiseptic surgery, it was nevertheless possible to enforce antiseptic precautions to a considerable extent in Thomas's operation. One advantage of the Porro-Müller operation was that it could be commenced before the commencement of labor.

DR. POLK being called upon to open the discussion, remarked that there was very little to be said upon the operation beyond what was contained in the paper, except, perhaps, to place the operation, and to disabuse the minds of its opponents as to its difficulties. He thought, in placing the operation, it was a mistake to put it in competition with Cæsarean section and its modifications. There were cases in which the Cæsarean operation was the only one that could be performed. In certain cases, he thought, the operation of embryotomy might well give way to gastro-elytrotomy. The latter operation rested between Cæsarean section and its modifications on the one hand, and embryotomy on the other. The laceration incidental to embryotomy was infinitely more detrimental than that produced by gastro-elytrotomy. This remark referred only to cases where there was the minimum limit to the deformity. Dr. Polk went on, and described, step by step, in detail the anatomical points in the two operations, and thought the evidence thus adduced showed that Thomas's operation was the simpler of the two.

DR. TAYLOR spoke in favor of oöphoro-hysterectomy, and was followed by DR. SKENE, of Brooklyn, who argued in favor of Thomas's operation.

DR. LUSK thought that when there was a dilated cervix, no operation was better than gastro-elytrotomy. It was also the only operation to be thought of in cases where there was a contracted pelvis over the head. He was not prepared, however, to say that gastro-elytrotomy would supersede all other operations.

Further remarks were made by DRS. GILLETTE and EMMET, and the discussion was closed by DR. GARRIGUES.

RHODE ISLAND MEDICAL SOCIETY.

Semi-annual Meeting held at Providence, December 21, 1882.

(Specially reported for THE MEDICAL NEWS.)

THE semi-annual meeting of the Rhode Island Medical Society was held in Providence, on December 21st, The PRESIDENT, DR. JOB KENYON, in the chair. The attendance was large.

The SECRETARY, DR. GEORGE D. HERSEY, read the records of the last quarterly meeting, which were approved.

DR. M. FIFIELD, of Centreville, presented a report of the following

CASE OF INTRA UTERINE TUMOR.

The patient is a woman 39 years of age, whose menstruation, beginning at 13 years of age, continued very profuse and frequent up to six years ago, the periods recurring every two or three weeks during the whole time. During the past six years there has been no menstruation, but very severe uterine hemorrhages have occurred at irregular intervals. One of these took place last July and was with great difficulty checked by the use of ergot and viburnum.

An examination at that time showed the abdomen to be greatly enlarged, the tumefaction extending above the umbilicus, its upper left side being distinctly rounded and hard on palpation. On examination per vaginam the cervix uteri was found shortened and softer than normal, with the os so patulous as to readily admit the tip of the finger which immediately encountered a firm, hard mass completely filling the uterine cavity. Since July there had been no recurrence of the hemorrhage until last week, when there was a profuse and alarming loss of blood. Walking is painful to the patient, but she can ride in an easy carriage in comfort.

The question is asked, Is the intra-uterine mass a fi-

broid tumor, and if so, what treatment is indicated? Is Battey's operation justifiable in the case?

DR. LUCY R. WEAVER said, regarding a case operated on by Dr. A. E. Tyng, and reported two years ago that a fibroid existed in that case, and Battey's operation was done; that almost immediately the tumor began to diminish in size and could now scarcely be felt at all and that the woman regarded herself as being now in perfect health.

DR. J. H. MORGAN, of Westerly, read the report of a case of

ANEURISM OF THE DESCENDING AORTA,

occurring in a Scotch stone-cutter, 38 years old, who was first seen by the writer April 19, 1882, soon after coming from Vancouver Island. Formerly in vigorous health, he had then become weak and emaciated. For fifteen months he had suffered from neuralgic pains in the right thigh and leg. A well-marked prominence existed in the lower dorsal portion of the spinal region, in which severe pain was caused by allowing his weight to come down forcibly on his heels. Percussion and auscultation gave only negative results. Caries of the vertebræ being diagnosticated, it was proposed to put on a plaster-of-Paris jacket, but to this measure the patient himself objected. The case went on without marked change until May 18th, when, after a day of less suffering than usual, death occurred suddenly. The autopsy showed the diaphragm to be prolapsed, the liver pushed downward and to the left, the stomach contracted, the spleen and pancreas normal, the heart crowded to the left, and the right lung compressed and adherent. On the right side of the spinal column and behind the kidney was found a ruptured aneurismal sac, communicating by a small orifice with the descending aorta. The sac had ruptured into the right pleural cavity. The writer emphasized the need of caution in the application of the plaster jacket, in face of the possibility that, as in this case, the spinal disease may have been caused by the pressure of an undiscovered aneurism.

DR. F. B. FULLER exhibited a specimen of

ENCEPHALOID OF THE TESTICLE.

At 12 years of age the man had received a blow in the scrotal region which immediately caused acute orchitis. This subsided, but the right testicle soon began to enlarge, and became painful. The condition changed but little for several years when the trouble increased rapidly for four months until the growth became so burdensome and painful that it was excised February 10, 1882. The tumor, which was the specimen shown, was the size of a fœtal head at term; its upper two-thirds were fibrous and contained cysts and enchondromatous masses; the lower third was encephaloid carcinoma. The patient recovered well from the operation, but very soon began to have severe pain in the abdomen which was from time to time relieved by the escape per rectum of large quantities of clots, blood, and pus. Death occurred in ten months, and post mortem there was found in the abdominal cavity a mass of encephaloid cancer the size of a man's head.

DR. W. H. PALMER, of Providence, read a paper on

CORONERS AND THEIR DUTIES.

The ancient origin of the system of investigation through the office of coroner was alluded to as dating back as early as the year 908 in England, in which country the officer, variously termed "coroner," "crowner," and "coronator"—either title signifying a direct representative of the crown—enjoyed uncommon authority and privileges, which the writer described. The establishment of the coroner system was said to be one of the earliest concessions made by the crown to the people—the coroner having first summoned a jury from the ranks of the common people.

In those early days the appointment of coroners was naturally hedged with due precaution, and it was directed that none but loyal and discreet knights should fill the position. In 1640 there was published in England a long and explicit summary of the coroner's duties.

Our advancing civilization is unable to dispense with the coroner system or its equivalent, notwithstanding, from time to time, public disapproval demands the abolition of the coroner entirely.

The coroner's office, organized to make inquiry into the cause of death, is one of special interest to the medical profession.

The different methods employed in some of the countries of continental Europe, where the office of coroner does not exist, were described.

Although the method of appointing coroners differs in the various States in this country, there is agreement in one direction, viz., coroners are almost universally appointed without special qualifications for the position.

It would be as rational to hand a stopped watch to a lawyer for him to investigate the cause of the trouble as to expect a non-medical coroner to properly and intelligently seek for the cause of the stopping of a human life, a machine so manifold more intricate and delicate. Now, in England, the office is filled almost entirely by medical men.

The writer claimed that in Rhode Island the authority and work of the coroner are neither merely supplementary nor inefficient, as has been alleged in the public press. He alone has authority to take charge of dead bodies in suspicious cases, to order exhumations, examinations, and analyses; to enter houses to investigate, to summon juries and witnesses, impose fines, etc.

The system at present employed in Massachusetts, whereby the office of coroner is supplanted by that of medical examiner, was reviewed in detail, and the following mentioned as among the most important features of that system:

1. The best element is that only medical men are appointed.

2. An inquest is held without the intervention of a jury, the opinion of *one* man prevailing instead of *six*.

3. At the option of the trial justice, the inquest *may* be held in private.

In the opinion of the writer, however, it did not seem probable that the Massachusetts system would take the place of the coroner.

The coroner system, *at its best*, is *the best*, and the defects charged against it are not *inherent* in the system, but arise from the carrying out of the application of the system.

DR. A. BALLOU thought the medical profession were not alive to the importance of having suitable men appointed coroners. He expressed his approval of the paper just read, and also his belief that the legislation in Rhode Island bearing on the subject is not inferior to that of other States. The system employed in Pennsylvania is very expensive, and, as managed, is far inferior to our own.

DR. CASWELL expressed his interest in and approval of the paper. He had thought, however, that the Massachusetts system was excellent and entirely successful.

DR. O'LEARY asked Dr. Palmer if it was within the province of a Rhode Island coroner to inquire beyond the *proximate* cause of death, *e. g.*, in case of drowning on board ship, shall the coroner investigate as to the seaworthiness of the ship, etc.

DR. PALMER replied that the jury should not be re-

stricted, and might seek for remote and contributory causes of death.

THE CENSORS' REPORT

was next in order, and was presented by Dr. S. S. Keene for the Board. It simply recommended that the applications for fellowship of Dr. Jean Antoine Baptiste Tanguay and Dr. George Reuben Smith, which were received at the last quarterly meeting, be referred to the next meeting. This report was accepted.

DR. ROBERT F. NOYES, of Providence, then read a paper on

PERITYPHLITIS AND PERITYPHLITIC ABSCESS.

The cæcum, covered in front and laterally by peritoneum, and posteriorly by cellular tissue, has functions that are peculiar and distinct. Its contents pass slowly and in a direction opposed to gravitation; hence the liability of the lodgement of fruit seeds and stones, bits of epithelial and fibrous tissue from the ingesta, etc. It may become enormously distended—even to the capacity of a gallon, and its walls greatly hypertrophied. The symptoms of inflammation of the cæcum and its appendages are pain in the right iliac fossa, vomiting, pain and numbness in the thigh, frequent and painful micturition, and the presence of regional swelling.

Regarding the appendix vermiformis cæci, it was said that it exists in the ourang and ape alone of the lower animals; that its non-uniformity anatomically, and in its investments, complicates the diagnosis; its orifice sometimes becomes occluded, causing atrophy; calculi may form in it; ulceration in the appendix is less apt to be followed by cicatrization than in case of ulceration of the cæcum, but perforation is more common in the appendix. Perforation may occur without the previous existence of symptoms severe enough to attract the attention of the patient.

The softening of the cæcum renders caution necessary in the use of copious injections, especially when the rectal tube is introduced. In the great majority of cases perforation of the vermiform appendix is caused by foreign bodies. Reference was made to Dr. Bartholow's description of cases of idiopathic perforation of the appendix.

Regarding the symptoms in perityphlitis, the dull pain is due to cellulitis, the sharp pain to peritonitis, the pain and numbness of the thigh to pressure on the lumbar plexus; the vomiting is due to obstruction of the intestine. The tumefaction is at first hard, and afterwards becomes softer. To diagnosticate perityphlitic abscess may be very difficult, but it is very important. Examine for swelling, pain, and fluctuation, and employ the aspirator needle in doubtful cases. In diagnosis the following must be considered in differentiating: Tumors due to fecal accumulation; psoas abscess; malignant disease; inflammation of right ovary; perinephritic abscess; movable kidney, with suppuration; abscess of the abdominal wall; in children hip-joint disease; and invagination, especially if at the ileo-cæcal region, when it may be very difficult to determine the diagnosis.

The prognosis in perityphlitis depends largely upon the etiology. It is more favorable when the cause is exposure to cold or traumatism. In case of abscess, the course taken by the pus largely influences the result. If it escapes into the intestine or bladder, it is more favorable than through the abdominal wall or upward through the diaphragm.

The writer had collected notes on 100 cases, of which 15 were fatal. Perforation of the appendix is almost always fatal, though a few cases have recovered.

In the treatment of perityphlitis, saline laxatives should be used, with enough opium to relieve pain and control peristalsis; turpentine fomentations; leeches may be applied to the ileo-cæcal region. There should be frequent examinations for abscess, and when found it should be opened by an incision parallel to Poupart's ligament. When pus is suspected, but fluctuation is not present, the exploring needle may be used. The needle is valuable in diagnosis, but can not supersede the knife. Out of 100 cases of abscess 31 were due to presence of foreign bodies, and in this class of cases the knife is far better than the needle. When an incision is made it should be carried down to the fascia transversalis, when deep-lying pus is suspected. Several authorities were quoted as to the proper time for opening the abscess. The sac of the abscess on percussion may give a tympanitic sound as though the intestine lay in front, but the writer had never found this condition present. The treatment in case of perforation of the appendix vermiformis should include opium, fomentations, and perhaps the application of the ice-bag in the iliac region.

DR. A. BALLOU cited three fatal cases in point:

1. The case was seen during the acute inflammatory stage. Opium and fomentations were used. A portion of the cæcum became gangrenous and was thrown off per rectum. The specimen was preserved.

2. The case of a woman of 200 pounds weight and seven months pregnant. There was no movement from the bowels and death occurred from inflammation. There was no tendency to abortion. The autopsy showed that two inches of the ileum had become invaginated by the cæcum, strangulated and gangrenous.

3. This case was similar to the second, the ileum being invaginated within the cæcum and gangrenous.

DR. WM. SHAW BOWEN, of Providence, then read a paper on a case of

ULCERATION OF THE LARYNX.

The patient, Mr. H., is 39 years old, of spare build, regular habits, and in comfortable circumstances. Six years ago he fell down stairs, striking his face on an open door, causing fracture of the nasal bones, and displacement of the vomer. A few months later a hard pimple appeared near the right ala nasi. It broke down and refused to heal. The disease extended up the nostril on the mucous membrane, destroying a portion of the vomer and middle turbinated bone. There was but slight involvement of the skin outside the nostril. A course of hot-iron treatment, in Boston, was followed by an apparent cure.

In December, 1881, he began to have slight soreness of the throat, cough, and hoarseness; swallowing was painful, especially of condiments; soon no solid food could be swallowed. A physician pronounced it to be laryngeal phthisis, and tried the usual remedies, with no avail. When first seen by Dr. Bowen the ulcerative disease had so far advanced that there had been extensive destruction of bone; œdema and cicatricial bands had left only a small orifice between the pharynx and the post-nasal space, so small as only to admit a fine bougie. There was a mass of mucous polypi in the nose, attached to the middle turbinated bone. The left tonsil was enlarged. The epiglottis was bare, somewhat rigid, and sensitive to the touch. There were a few nodular masses on its dorsum. It was very difficult to obtain a view of the vocal chords. There was harassing cough, and the voice was gone. Except in carcinoma or throat phthisis, a worse condition of the throat is rarely seen.

No syphilitic history was acknowledged, but it was decided to try the mixed anti-syphilitic treatment. Mercury, iodide of potassium, cod-liver oil, and sea-water baths were employed. Morphia and powdered starch were dusted over the raw surfaces, together with

the application of olive oil. This treatment was continued three weeks without marked change in the local condition. The diagnosis of laryngeal lupus was then made. The arytenoideus was involved in the ulceration, some of the small nodular masses existing on its surface.

The treatment was now changed. A solution of nitrate of silver (480 grains to the ounce) was carefully brushed over the ulcerated surface. The first two applications caused severe laryngeal spasm, and no marked improvement followed the first twenty applications. The voice then became a hoarse whisper, and the cough was much less troublesome. The treatment was continued six weeks, resulting in marked improvement in all the local conditions. The tincture of the chloride of iron and iodoform were also used locally. In November, the voice had improved to a hoarse tone, and the dysphagia was gone. The silver and iodoform treatment was then stopped, and a stimulating inhalation of benzoin used instead.

DR. DANIEL O. KING, of Pontiac, reported

A CASE OF PERITYPHLITIC ABSCESS,

which recently occurred in his practice, in a boy 4½ years old. The first symptoms were pain in the right iliac region, tympanitis, and vomiting. An injection relieved the symptoms, which returned the next day, however. Laudanum and chloric ether were given internally. The case went on for a week, when the writer was discharged. He was recalled to the case ten days later, and found the patient in a most critical condition, apparently very near death. A soft boggy swelling the size of an egg was now found in the right iliac space. The swelling was tympanitic on percussion and gave no distinct fluctuation. The patient was etherized, and by means of a hypodermic syringe a few drops of pus, having a fecal odor, were withdrawn. An incision, two inches long, was then made parallel to Poupart's ligament and carried down to the fascia transversalis. The fascia was punctured by the needle, letting out a fluid which the microscope showed to be purulent. A warm carbolized dressing was applied. The patient improved. Fecal matter oozed through the incision for some days, and some fragments of apple pie, eaten by the boy contrary to directions, also oozed out. The boy is now strong and well.

In this case the writer thought the abscess was caused by perforation of the vermiform appendix, for if the abscess had been primary it would have pointed into the intestine at once.

THE APPOINTMENTS OF DELEGATES

to the annual meetings of other State Societies were then named by the Chair, as follows:

Connecticut.—Drs. O'Leary and Browning.
New York.—Drs. Ely and W. O. Brown.
Vermont.—Drs. Robbins and O. C. Wiggin.
New Hampshire.—Drs. A. Ballou and W. R. White.
Massachusetts.—Drs. Miller and Swarts.
New Jersey.—Drs. Parks and Bullock.
Maine.—Drs. Anthony and Bowen.

DR. CASWELL reported two more

LITHOLAPAXIES.

The first was a secondary operation on a patient in whose bladder a few fragments remained after the first operation. The secondary operation was done in October last, occupied forty minutes, and resulted in the washing out of ninety grains of stone.

Case second, that of a man forty-seven years old, who was operated on, in 1876, by the old lithotrity method, eleven sessions having been required to free the bladder from fragments. He began to suffer again last spring. At the recent operation Dr. Caswell, believing the stone to be small, made a preliminary washing before introducing the lithotrite at all. A small stone was at once drawn into the eye of the instrument by suction, and was removed while so engaged without difficulty. The stone was round, $\frac{7}{16}$ of an inch in diameter, flattened into a disk shape, and perfectly whole and symmetrical. It was formed of urates and weighed 10 grains. Further examination revealed the presence of a second stone in the bladder, which was crushed and washed out at once, making 31 grains in all removed. The entire operation lasted half an hour. The patient was up and about his room the next day, and attending to business in a week.

Dr. Caswell emphasized the great advantages and superiority of litholapaxy over all other stone operations, and compared it with the far more dangerous lithotomy, especially in such a case as he had just reported.

He then exhibited Dr. Bigelow's modified evacuating apparatus, and explained its application.

DR. W. E. ANTHONY, of Providence, read

AN OBITUARY NOTICE OF DR. GEO. CAPRON,

who died September 21, 1882. It was mentioned that in a practice covering sixty years, Dr. Capron had attended more than ten thousand confinement cases, a branch of practice in which he excelled.

PRESIDENT KENYON announced the death on November 28th, of Dr. George E. Mason, of Providence, a Fellow of the Society, and appointed Dr. J. W. Mitchell to present an obituary at the next meeting.

DR. E. M. SNOW said there had been 109 deaths from typhoid fever, in Providence, since September 1st.

Adjourned.

OBITUARY.

GEORGE FOX, M.D.

DR. GEORGE FOX died in this city on Wednesday, the twenty-seventh day of December, in the seventy-seventh year of his age. Although Dr. Fox relinquished his private practice and his professional appointments almost thirty years ago—*grande mortalis ævi spatium*—his death will still be felt in the medical community of which he was a well-known and distinguished *confrère*.

Dr. Fox belonged to a family in the Society of Friends, of high social position and extended influence, in the city of Philadelphia. He was graduated from the University of Pennsylvania, Bachelor of Arts, in 1825, dividing the second honor in his class with the late Adolphe E. Borie. The same year he began the study of medicine under his brother, Dr. Samuel M. Fox and Dr. Joseph Parrish, and received the degree of Doctor of Medicine from the University, in the spring of 1828.

During the two following years he was resident physician in the Pennsylvania Hospital; Dr. James A. Washington being his colleague the first year, and Dr. Ralph Hamersly the second. During his term of service as resident he devised the apparatus for fractured clavicle, still known as the *Fox apparatus*, and of which Sargent well says in his *Minor Surgery*, "No one who has employed it will be disposed to use any other as a substitute." In 1848, Dr. Fox was elected one of the visiting surgeons to the Hospital, and fulfilled all the duties of that position with the greatest fidelity so long as he remained in the city. On the organization of the Wills Hospital for the indigent blind, and lame, Dr. Fox with Drs. Hays, Littell, and Isaac Parrish, were elected surgeons, and he diligently served that institution until his election to the Pennsylvania Hospital, when he resigned his position at the

Wills. After resigning from the Wills Hospital as surgeon, Dr. Fox was elected one of the Board of Managers, and acted as such until his removal to the country.

In 1831, Dr. Fox was elected a Fellow of the College of Physicians, and always showed great interest in its affairs. He was an active member of its Building Committee, and took a leading part in the selection and purchase of the site of the present hall of the College and in its erection. He possessed, it may be said, peculiar and special qualifications, which enabled him to be of great assistance to the College in these transactions.

At the time of the formation of the American Medical Association, and for several years afterwards, Dr. Fox was very prominent in advancing its interests and furthering its objects. He attended the meetings as one of the delegates from the College of Physicians.

In the practice of his profession Dr. Fox was eminently successful in *curing his patients;* or, if such phraseology be not acceptable, patients were very apt to get well under the means he used. As an instance of this, of all the cases in which he was forced to amputate a limb at the Pennsylvania Hospital, some twenty in number, only one died. He was distinguished for good judgment, and he was prompt, energetic, and not sparing of himself when his patients needed him. Moreover, to use a frank phrase, *il avait les opinions tranchus;* he was not habitually indifferent as to which course to pursue, but he was decided in believing one certain thing was the one thing to do, and that he did.

Dr. Fox was happily married on September 25, 1850, to Sarah D. Valentine, of Bellefonte, by whom he had six children, four sons and two daughters, all of whom survive him. One of his sons, Joseph M. Fox, has graduated in medicine, and been resident in the Pennsylvania Hospital; thus far following in his father's footsteps. *Dos magna, virtus parentum;* this is true in our profession as elsewhere.

NEWS ITEMS.

WASHINGTON.

(From our Special Correspondent.)

SPECIAL LEGISLATION TO CONTINUE THE IMMIGRANT INSPECTION SERVICE TO THE NATIONAL BOARD OF HEALTH.—At the semi-annual meeting of the National Board of Health held in Washington, D.C., December 12–14, the following communication was submitted:

WASHINGTON, D. C., December 12, 1882.

At a meeting of representatives of State and other boards of health, who have come here to place before the National Board of Health the importance of continuing the sanitary inspection of immigrants for the prevention of the introduction of contagious diseases into this country, and their spread throughout the country, W. M. Smith, M.D., Health Officer of the port of New York, was chosen chairman, and Dr. Henry B. Baker, Secretary of the Michigan State Board of Health, was chosen secretary.

The subject having been verbally presented to the National Board of Health, at its meeting this day, and the Board having requested a summary statement in writing of the views of those present, the subject was discussed at some length, and a communication to the National Board of Health was formulated as follows:

To the National Board of Health:

GENTLEMEN: The undersigned respectfully represent that the maintenance, at the principal ports of entry in the United States, of an efficient sanitary inspection of immigrants as to their protection from smallpox, and as to their liability to communicate that disease, is necessary to prevent the frequent introduction of smallpox and other contagious diseases among the people of this country; and that such inspection is necessary to secure efficient action at ports of departure and on board ships on the part of the transatlantic steamship lines engaged in the transportation of immigrants.

There is also urgent need for constant watchfulness to detect contagious disease occurring in immigrants after they have passed the ports of entry—the disease not having appeared when they were examined at the port of entry.

We therefore urge upon you the necessity for continuing such inspections as have been established.

This inspection service is such that its benefits have no relations to State boundaries, but its protective influences extend widely throughout this country, consequently expenses therefor should not properly be borne by any local or State board of health. We believe that it is the duty, and one of the highest duties, of the national government to maintain this inspection service whenever needed in this country.

In our opinion, the sum of $25,000 will be sufficient for this service during the remaining months of this fiscal year.

Wm. M. Smith, Health Officer, Port of New York. John H. Rauch, Secretary State Board of Health of Illinois. H. R. Mills, M.D., Henry B. Baker, M.D., Secretary Michigan State Board of Health.

This report and the recommendations were concurred in by a large number of representatives of State and city boards of health who were present.

This communication was transmitted by the Board to Congress, and was referred to the committee on Epidemic Diseases, and on the Public Health in the Senate and House of Representatives.

Senator Conger and Mr. Roch, of Michigan, have since introduced bills into the two Houses appropriating $25,000 to enable the National Board to continue the service during the remainder of the fiscal year.

NEW ORLEANS.

(From our Special Correspondent.)

PRESENT PREVALENCE OF MALARIA, AND ITS CLINICAL HISTORY.—The weather here has been exceptionally beautiful. Frosty nights have been followed by cloudless days and a bracing atmosphere. Notwithstanding this fact, the admissions to the Charity Hospital have been unusually large—averaging nearly fifty a day. Almost the whole of these new admissions are persons suffering from malarious affections. Although the first range of temperature arrests at once the further development of the malarial poison, there can be no question that it is liable to determine attacks in the persons of those previously exposed to its influence.

After more than two score years of study of the phenomena of this class of diseases, your correspondent can declare that the most remarkable feature that they present to his mind is the difference in symptoms which they present in some seasons as compared with other seasons. During the present year, diarrhœa and malarial coma have been the most common and dangerous symptoms. In some former years hæmaturia and congestive chills have been the principal sources of danger. This year he has not met with a case of either of these forms of pernicious fever.

Why should these differences obtain in the effects of a poison which is commonly looked upon as isomorphous?

There appears to be no way of explaining the fact, except by admitting differences in toxic qualities of

different crops, or by claiming that the systems of those exposed undergo some unknown changes which determine the variations in the effects of the poison. The former appears to be the more rational theory.

The mortality rate from this class of diseases has not been great. The diarrhœas have in many instances been cured by cinchonism. Where this has failed, small doses of sulphate of soda and morphia have ordinarily accomplished a cure.

Quite a number of cases have been complicated by cardiac troubles. The most common of these has been dilatation caused by undue physical exertion in that state of innutrition and muscular atony caused by chronic malarial toxæmia. These cases recover with surprising certainty and rapidity as repair in the nutritive processes and restitution of degraded fluids are effected. Of course, rest from physical exertion is a *sine quâ non* to recovery.

Inflammations of cardiac structures have also complicated several malarial fever cases.

Your correspondent has now under observation a case of endocarditis associated with intense malarial cachexia, and a hypertrophied spleen, but with no history of rheumatism.

We are well satisfied that the malarial cachexia, like that of Bright's disease, invites inflammations of both mucous and serous structures.

We had one patient die of symptoms which he attributed to ante-mortem vascular clot. A previously strong man had two attacks of malarial fever during two months preceding the first observation. At this date he presented the appearance of alarming deterioration of the systemic fluids, but he was encouraged to hope for a reasonably prompt restitution. During a violent fit of vomiting he complained of sudden pain at the upper part of the sternum and in the præcordial region. At our next visit we found a very intermittent heart, with cool extremities and surface and anxious countenance. A peculiar systolic murmur was heard over the heart and quite as distinctly over the upper part of the sternum. Death ensued about forty-eight hours afterwards, but no autopsy was permitted.

BOSTON.

(*From our Special Correspondent.*)

Dr. Carpenter's Fifth Lecture on Human Automatism.—The first subject discussed was the automatism of those perceptive processes, by which are determined the distance, direction, and notably the solid form of external objects. In us this is acquired instead of being congenital as in the lower animals. Many observations of infants and of adults who have recovered sight by means of the removal of the lens (cataract) prove the truth of this statement, and show that a combination of the impressions received from several senses is necessary in order to create the ideas we possess of external objects. A person blind from birth, upon obtaining vision, will not recognize forms like the cube, sphere, and pyramid, notwithstanding the sense of touch has long since made them familiar. Locke doubted this and the question, then unanswerable, since his time has received repeated answer. For example, a young man whose sight was restored in one eye, was unable by vision to distinguish a cat from a dog, both of which he was accustomed to fondle. He finally taught himself to know the cat by handling her frequently, meanwhile looking at her intently. A remarkable case was that of a child aged 4 years, blind from birth, who recovered sight by the operation for cataract. He gave evidence of his ability to see. The operation had occurred in a house with which the boy had become familiar by feeling his way about. After the operation, while going over the house, he at first felt and looked as he went, but for some time evidently preferred the guidance of touch, and eventually began to find his way by sight alone. Upon returning to his home, however, he was quite unable to discover his way by sight among objects perfectly familiar to him and for a long time closed his eyes in going from place to place. But when taken to a place entirely strange to him he used his sight without embarrassment, and finally overcame the difficulty in using sight at home.

In a third case a blind seamstress obtained her sight, and when shown a pair of scissors could not recognize without touching them. These examples indicate the amount of education necessary in the training of our automaton, which, once disciplined, subsequently makes no mistake unless something is wrong in the mechanism.

Our perception of solid form is the result of a union of the effects of two modes of perception, as is proved by the stereoscope. In looking through this instrument two slightly dissimilar pictures, such as are thrown upon the retina of the two eyes, when the observed object is near, by their difference in direction form an object in relief and the mind thus perceives one solid object instead of two flat ones. This conversion is an automatic process the result of education. Sir Charles Wheatstone, who invented the stereoscope, also investigated the singular fact that a body first held at a distance, and then closer to the eyes, always presents the same size to the mind, although the image on the retina is much larger. By bringing the pictures in the stereoscope nearer together, thus causing the eyes to converge, the object shown seemed to diminish in size, although the images on the retinæ were not changed in dimension. In a similar manner, if the pictures were separated until the direction of the eyes was made parallel, the size of the object was made apparently to increase in size. This proves that the idea of the size of near objects and the relative distance of their posts depends upon an automatic comparison of the size of the image on the retinæ and the degree of convergence of the eyes. (Dr. Carpenter discussed these phenomena more at length in the *Edinburgh Review* about 1860.)

At distances which make the direction of the eyes sensibly parallel, we no longer possess this muscular aid in determining size and relief, and our perceptions, depending mainly upon light and shade, are accordingly less distinct. At a distance we cannot distinguish objects actually in relief from carefully painted flat surfaces. This is really due to the absence of convergence, as proved by the fact that a photograph, the mountings being concealed, if seen with one eye alone appears to be an object in relief.

Passing to the automatisms of the higher intellectual processes, the lecturer discussed those uniformities which, some being general in the race, others being the result of special training, and already studied under the name of "laws of thought," markedly illustrate the doctrine of automatism as well as the power of the will to devote itself to such processes as may be chosen. Wordsworth has testified that his best poetry was created by allowing his mind to direct itself intently upon all the phases of his subject, and then waiting for a spontaneous outflow of poetical imagery from his mental mechanism. Mozart, whose musical faculty had from childhood been trained with most assiduous care, had only to think out the general plan of a composition, deciding as to the place to be given to solo, recitation, duet, quartette, etc., and then allow his thought to work of itself and evolve its own results. In the same way trained mathematicians solve difficult problems. But most instructive of all is the action of

memory. We endeavor to recall some half-forgotten fact, name, or date. After fixing the attention upon the subject for a certain length of time, and recalling every accessible circumstance, we find it better to withdraw the attention, to "hang up" the subject, and leave the matter to time. The general result will be a sudden return of the missing fact to the consciousness. In all these cases of "unconscious cerebration," it is noteworthy that we must first give direction to the process, and, moreover, that in order to obtain results we must previously train the automata. Other instances were given.

Evolutions of the judgment are also common under the same conditions of a previous training, antecedent fixing of the attention, and, as far as possible, a voluntary development of the process. Thus an executor unable to decide as to the best solution of a difficult provision in a will, arranged a plan which, though unsatisfactory, seemed the most feasible, and then dismissed the matter from his mind. Some days later, on waking from a sound sleep, a perfect plan flashed into his consciousness and was accepted without change. Experience has shown that these automata, once trained, work far better when left alone than when the attention is fixed upon them. When we apply the theory of automatism to our beliefs, there arises the question as to whether we are responsible for them, and whether we can believe what we wish to believe. The reply is that if we have accustomed ourselves to give due weight to all the evidence which may affect our conclusions, we are not responsible for our belief. We may, however, close our mental eyes to certain aspects of the case, just as an unjust judge may refuse to admit evidence on one side and unduly admit it on the other. In such case we are directly responsible for what we believe.

THE PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE.—It is proposed to establish in this city a Polyclinic, and the faculty, so far as arranged, is constituted as follows: Dr. Chas. H. Burnett, Diseases of the Ear; Dr. J Solis Cohen, Diseases of the Throat and Nose; Dr. Henry Leffman, Clinical Chemistry and Toxicology; Dr. Richard H. Levis, Operative and Clinical Surgery; Dr. Morris Longstreth, Pathology and Post-mortem Examinations; Dr. Chas. K. Mills, Diseases of the Mind and Nervous System; Dr. Thos. G. Morton, Orthopædic and General Surgery; Dr. John B. Roberts, Applied Anatomy and Practical Surgery; Dr. Wm. Thomson, Diseases of the Eye; Dr. Jas. C. Wilson, Diseases of the Chest and General Medicine; Dr. John B. Roberts, Secretary. It is proposed to have a large building devoted solely to the purposes of the school. Dispensaries will be conducted in connection with each department, and instruction will be clinical and demonstrative, in series of short courses of from six to eight weeks; studies may be pursued in all branches or on special subjects. Demonstrators and assistants, with the professors, will give clinical lessons in each department daily. It is also proposed to furnish hospital accommodations for cases which require it.

ANNUAL ADDRESS BEFORE THE PHILADELPHIA ACADEMY OF SURGERY.—Dr. William Hunt will deliver the Annual Address before the Philadelphia Academy of Surgery on Monday evening, January 8th, at 8 o'clock, in the Hall of the College of Physicians —subject, Esmarch and Antisepsis.

COMPLIMENTARY DINNER TO PROF. AUSTIN FLINT, SR.—A number of prominent members of the medical profession of Philadelphia will entertain Prof. Flint at a dinner on next Friday evening. The chair will be occupied by Prof. Alfred Stillé.

SEMI-CENTENNIAL OF THE UNIVERSITY OF ZURICH.—The University of Zurich will, at the end of the current winter term, celebrate the fiftieth anniversary of its foundation.

LUMLEIAN, CROONIAN, AND GULSTONIAN LECTURES.—The Lumleian Lectures for 1883, at the Royal College of Physicians, will be delivered by Dr. A. B. Garrod, on "Uric Acid; its Relations to Renal Calculi and Gravel." The Croonian Lectures will be delivered by Dr. J. E. Pollock, the subject being "Modern Theories and Treatment of Phthisis;" and the Gulstonian Lectures, on the "Nature, Causes, and Treatment of Sterility in Woman," by Dr. Matthews Duncan.

STRAFFORD DISTRICT (N. H.) MEDICAL SOCIETY.—The 75th annual meeting of the Strafford District, New Hampshire, Medical Society was held at Dover, on December 19th, with Dr. S. C. Whittier, of Portsmouth, Chairman, and Dr. C. A. Fairbanks of Dover, Secretary. The following officers were elected for the ensuing year:

President.—Dr. John R. Ham, of Dover.
Secretary.—Dr. Charles A. Fairbanks, of Dover.
Treasurer.—Dr. Charles A. Tufts.

PORRO'S OPERATION.—On Nov. 27, DR. C. GODSON, Assistant Physician-Accoucheur to St. Bartholomew's Hospital, performed Porro's operation on a dwarf, aged 24, whose pelvis was distorted to an extreme degree. The patient was returned to her bed one hour after the commencement of the operation; the child was a girl, twenty inches in length, and eight pounds and a half in weight; the mother being but fifty-two inches in height. Up till November 29, the case was reported as doing well; the temperature had not risen above a maximum of 99.4° Fahr., and the pulse had never exceeded 80 beats per minute.—*British Medical Journal*, Dec. 2, 1882. Later accounts report steady progress toward cure.

THE PUBLIC HEALTH IN CONNECTICUT.—Dr. C. M. Chamberlain, Secretary of the State Board of Health, has just submitted his report for November, from which we learn that the record for November is in general more favorable than that for several preceding months. The prevalence of *scarlet fever* and of *diphtheria* increases the death-rates in several places. The probability of an increase in the frequency and malignancy of scarlet fever, stated in the last report, has become a certainty in repeated instances.

Measles is not reported in the mortality list, nor from any part of the State. Its prevalence for the last few years would indicate that there were few children left that had not had this disease, and in one or two instances its recurrence for the third time was mentioned.

Whooping-cough is reported more frequently than it has been for several months. Cases are stated to be in Simsbury, South Manchester, Haddam, and in the southern part of the State.

Diphtheria is reported from Avon, Hampton, Watertown, and Manchester—a few cases in each place.

The same general tendencies in *typhoid* and *malarial fevers* that have been noted the last few months continue. There is not any alarming prevalence of typhoid fever, nor has there been any degree of prevalence that would have been noticeable in former years, except in certain localities where there have been localized epidemics. The cases of typhoid fever are peculiarly interesting, because they are happening in localities where a case has not been reported for years, or where there have been very few cases. There has not yet been reported, taking the State as a whole, as

many cases as occurred each year on an average before the appearance of malaria, although this year approaches it.

There was in many places, and in general everywhere, as far as reports are received, an unusual amount of sickness during the autumn months, more marked where the local unsanitary conditions were worst. There is no occasion for a panic over the appearance of scarlet fever, but it is the part of wisdom to prevent its spread as much as possible. The utility of a hospital for contagious diseases suggests itself strongly when we see child after child in a poor man's family attacked by contagion from which he might have been saved could the first case have been isolated, as has been done with success again and again by means of such institutions. The idea is not a popular one at first, but others less so have proved their claims for recognition.

Lung fever appears early, and apparently the mortality corresponds with that of last year. Above the average cases are reported from North Manchester, Watertown, Hampton, and Avon, and one fatal case from Guilford.

Review of the Situation.—In comparison with preceding months this has been quite a healthful one. But the large percentage of zymotic diseases, and the amount of sickness indicated, show plainly that there were many agencies at work that could have been prevented.

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending December 23, 1882, indicate that cholera morbus, diarrhœa, typhoid fever, and diphtheria have increased, and that intermittent fever, pneumonia, dysentery, and remittent fever have decreased in area of prevalence. Including reports by regular observers and by others, diphtheria was reported present during the week ending December 23, or since, at 16 places, scarlet fever at 10 places, and measles at 4 places. Smallpox was reported at Richmond, Osceola County, December 27.

PRECAUTIONS AGAINST CHOLERA.—Dr. Hampshire, the Senior Medical Officer of Penang, India, in his report for the month of September, intimates that the spread of cholera in the East and around the Straits, and its gradual extension in a westerly direction have caused considerable anxiety to the health authorities. To prevent its spread, when it occurs periodically, all measures have been taken so far as the legal powers permit, but native prejudices do not allow of their being carried out as effectually as in European countries. Doubts are entertained by the public, under the at present necessarily imperfect verification and registration of disease, as to whether all cases of cholera that have occurred have really been registered as such; but during the past few months the death registers at the different town and suburban police stations have been frequently examined, with the view of detecting any local increase in the mortality, should such occur. And in the case of doubtful entries, further inquiries have been made at the house of the deceased, among relatives and friends, in order to verify the diagnosis.

Among Chinese, who bury their dead in coffins hermetically sealed, with free disinfection as a preliminary, no great danger is involved in the burial rites; but among Hindoos and Mahommedans the body is retained in a room, crowded with relatives and friends, for a period varying from twelve to thirty-six hours, no disinfectants being used in the meanwhile. It is urged that, as Hindoos and Mahommedans, many of whom are aliens, constitute less than fifty per cent. of the population, some concession on their part is due to the majority of the population.

OBITUARY RECORD.—Died in Munich, on Dec. 5th, PROF. VON BISCHOFF in the 75th year of his age. Prof. v. B. was born in Hanover, Oct. 28, 1807, and studied natural science and medicine in Bonn and Heidelberg. After having served as an assistant in Berlin and Bonn, he was called in 1836 to Heidelberg to the chair of Comparative and Pathological Anatomy; in 1843 he was called to Giessen to the chair of Anatomy and Physiology, and 1855 to the same position in Munich, which he filled up to the time of his death.

His reputation rests on his numerous and valuable contributions to the embryology of mammals.

NOTES AND QUERIES.

MEDICINÆ SPECIALIS MAGISTER.

To the Editor of THE MEDICAL NEWS.

SIR: I see it stated in a recent journal that the Faculty of Medicine in Paris proposes creating "a higher doctorate than the simple M.D. It is proposed to confer the degree of "Doctor of Medical Sciences," after special examinations, and perhaps only after original work. The same journal goes on to say that America rapidly adopts European ideas, and that we may perhaps soon hear of a similar degree in this country. It has been rumored in the recently published accounts of the New York Post-graduate Medical School that there is a possibility of a degree higher than M.D. being conferred by that institution. If this or similar colleges for graduates, hereafter established, confer a degree, nothing appears to me so appropriate as "Master of Special Medicine." Such colleges are especially designed to give instruction in the specialties; hence the title "Medicinæ Specialis Magister" (M.S.M.) seems a proper designation for one who has passed an examination in such branches. It corresponds with the present custom of conferring the higher degrees in arts and surgery, as, for example, Artium Magister, Scientiæ Magister, Chirurgiæ Magister, and is, I think, preferable to "Doctor of Special Medicine," or "Doctor of Medical Specialties," which might also be suggested with a considerable degree of propriety.

Yours respectfully,

JOHN B. ROBERTS.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 25, 1882, TO JANUARY 1, 1883.

PERIN, GLOVER, *Lieutenant-Colonel and Surgeon.*—Granted leave of absence for one month, from the 19th inst.—*S. O. 217 Department of Dakota, December* 20, 1882.

BILL, JOSEPH H., *Major and Surgeon.*—Will report to the commanding officer, Fort Omaha, Neb., for duty.—*Par. 4, S. O. 134, Department of the Platte, December* 21, 1882.

KILBOURNE, H. S., *Captain and Assistant Surgeon.*—Granted leave of absence for one month, with permission to apply through Headquarters Military Division of the Missouri for an extension of two months.—*S. O. 218, Department of Dakota, December* 21, 1882.

REED, WALTER, *Captain and Assistant Surgeon.*—Relieved from duty as attending surgeon, headquarters Department of the Platte, and will report in person to the commanding officer Fort Omaha, Neb., for duty.—*S. O. 134, Department of the Platte, December* 21, 1882.

TURRILL, H. S., *Captain and Assistant Surgeon.*—Upon being relieved from duty at Fort Omaha, Neb., will proceed to Fort Fred. Steele, Wyoming, and report to the commanding officer of that post for duty thereat.—*Par. 5, S. O. 134, Department of the Platte, December* 21, 1882.

HOPKINS, WM. E., *Assistant Surgeon.*—Granted leave of absence for two months, to commence January 1, 1883, with permission to apply for an extension of two months.—*Par. 1, S. O. 88, Military Division of the Atlantic, December* 28, 1882.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

ORIGINAL LECTURES.

PHILADELPHIA COUNTY MEDICAL SOCIETY LECTURES.

ON THE PHYSICAL EXPLORATION OF THE LUNGS BY MEANS OF AUSCULTATION AND PERCUSSION.

A course of three lectures delivered by invitation before the Philadelphia County Medical Society.

BY AUSTIN FLINT, M.D.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

LECTURE II.

AUSCULTATION.

Delivered December 16, 1882.

THE exploration of the lungs by means of auscultation divides itself into the study: *First*, of the normal respiratory sounds and their abnormal modifications; *second*, of adventitious sounds, or râles; and, *third*, of vocal sounds, the latter including, with the loud or laryngeal, the whispered voice.

STETHOSCOPES.

The question whether auscultation should be mediate or immediate, is easily disposed of. It should be practised in both ways, according to the circumstances in particular cases. Laennec, as is well known, employed only mediate auscultation. He probably failed to recognize the value of immediate auscultation, because all his observations were made exclusively with the stethoscope. Some of those present may be interested in seeing the kind of stethoscope which Laennec employed. His first instrument was a cylinder of paper, consisting of three quires rolled together and kept in place by paste. He then tried instruments made of metal, glass, and wood, instead of the paper cylinder. Quoting his words, "In consequence of these various experiments, I now employ a cylinder of wood an inch and a half in diameter and a foot long, perforated longitudinally by a bore three lines wide, and hollowed out into a funnel shape to the depth of an inch and a half at one of its extremities. It is divided into two portions, partly for the convenience of carriage and partly to permit its being used of half the usual length. The instrument in this form—that is, with the funnel-shaped extremity—is used in exploring the respiration and the râles; when applied to the exploration of the heart and the voice, it is converted into a simple tube with thick sides, by inserting into its excavated extremity a stopper or plug traversed by a small aperture, and accurately adjusted to the excavation. This instrument I have denominated the *stethoscope*."

The stethoscope which I exhibit has an interest aside from the illustration of the kind which Laennec used. It not only belonged to Laennec himself, but was undoubtedly made with his own hands. Its authenticity, as having belonged to Laennec, is indubitable. It was given to me by a former colleague, the late Professor Choppin, of New Orleans, and it was given to him in Paris, by an old physician, who was Laennec's *interne* in the Hospital Necker, and who received it from Laennec himself. Laennec, as is known, was accustomed to make stethoscopes for his own use and for his friends. Moreover, the instrument bears intrinsic evidence of having been made by an amateur mechanic. When in the possession of the *interne* referred to (whose name I have forgotten), it was evidently not regarded with the same respect which it now claims, for the aural end has the traces of a penknife, showing that this sort of petty vandalism is not exclusively an American trait.

In connection with the stethoscope made by Laennec, I exhibit another, which is of interest, as having belonged to Valentine Mott, who obtained it in Paris, when the stethoscope devised by Laennec was in common use. This instrument, as you perceive, was made by a true mechanic. It is nicely polished and the ends are encircled with ivory.

In a recent lecture on the "Evolution of the Stethoscope," Samuel Wilks, of London, says, "I know not who invented the instruments with flexible tubes, but I have no doubt that a search into medical history would tell us." The stethoscope, with a single flexible tube, was devised by Carter Nestor Pennock. It was a great improvement on the wooden cylinders of every variety of shape devised by auscultators in different countries. Pennock's stethoscope consisted of a bell-shaped pectoral portion of metal, connected by a hollow flexible tube with a metallic ear-piece, the latter being introduced within the meatus auditorius. A still greater improvement was the binaural stethoscope devised by Cammann, in 1854. The advantages of this stethoscope are so great that, after a fair trial by any one, it is sure to supersede any other at present in use. After nearly thirty years from the date of its introduction by Cammann, it has come into considerable, but not as yet general, use throughout our own country, and it is but little used in other countries. I can speak of this instrument after ample experience, inasmuch as I have used it almost daily since 1855.

In my work on *Physical Exploration*, published in 1856, I stated that it was more difficult to judge of the quality and pitch of sound transmitted by Cammann's stethoscope, than with the wooden cylinder. This was an error, arising from my not then having used that stethoscope sufficiently to appreciate it fully. I corrected the error in a subsequent edition, but the error was quoted by Walshe, and appears in all the subsequent editions of his work on diseases of the lungs. Much to my regret, therefore, I may unwittingly have done something toward retarding the adoption of the instrument by our British brethren. Wilks, however, in his recent lecture, already referred to, appears to consider the binaural instrument as the result of the "evolution of the stethoscope" up to the present time, on the "principle of selection and the survival of the fittest," and he remarks that "the primitive instruments are indeed only to be found amongst the fossilized curiosities—the relics of former ages—on the antiquated shelves of some very old medical practitioner." The advantages of the binaural stethoscope relate to a conduction of sounds far better than by any uniaural instrument, and to greater facility in its employment. But there are certain obstacles to be overcome in the way of the appreciation of the first of these advantages. Want of knowledge of these obstacles is, I am persuaded, a reason for the fact that, after nearly thirty years, this stethoscope, except in some parts of our own country, is not in common use. In the first place, many stethoscopes, sold as the binaural stethoscope of Cammann, are essentially defective in their construction. Let me

indicate the points which are often overlooked by instrument makers. Cammann arranged the curves at the aural extremities so that when the terminating bulb is inserted into the ear, the opening in the bulb should have the direction of the external auditory canal. The conduction of sound is chiefly by the column of air within the instrument. This fact is readily demonstrated by obstructing one of the tubes leading to the pectoral end; the sound is prevented from reaching the ear on the side of the obstructed tube.

Another point in the construction is the size of the terminating bulb. This should not be too large to enter the meatus readily; and, on the other hand, if too small, passing too far into the meatus, it occasions discomfort and even pain. If these points be not properly attended to in the construction, the instrument is almost useless, and many instruments which have come under my notice have been defective therein. The flexible tubes should not be stiff. If they be so, every movement of the pectoral extremity acts within the ear as a lever, and occasions discomfort. The flexible tubes should move noiselessly. Sometimes the tubing used gives rise to a creaking sound which obscures other sounds. The elastic or the spring which is to hold the ends of the instrument within the ear should be neither too weak nor too strong. All these are minute points, but they are essential. It is proper to state that they are attended to by the instrument makers who made the first stethoscope under the personal direction of Cammann, Messrs. Tiemann & Co., and I have seen stethoscopes made by Ford, of New York, with which no fault could be found. I am afraid it is not safe to trust to the majority of instrument makers, and yet I hesitate to make a sweeping assertion of this kind.

Another obstacle applies to all perfectly constructed stethoscopes, namely, a humming sound belongs to the instrument, and this, for a time, confuses the attention. After a little use this obstacle disappears, the humming ceases to be observed, and the attention is free for the chest sounds. Before this, however, the instrument is often thrown aside as unsatisfactory. I have had much experience in giving practical instruction in auscultation to classes, and I have always found that at the commencement of a course most members of a class appreciate thoracic sounds better with the ear applied directly to the chest than by the use of the binaural stethoscope, but after a short time the stethoscope becomes so attractive that it is difficult to enforce sufficient exercise of the ear in immediate auscultation.

Wilks, in his interesting lecture on stethoscopes, refers to a fact first pointed out to him by Andrew Clark, which relates to a peculiarity of the binaural instrument in the objective appreciation of sounds. It is as follows: "If each ear-piece be separately used, and any sound be made near the mouth-piece, it is heard in the ear itself; but if the two pieces are employed together, the sound is heard at the spot where it is produced." "This fact," he adds, "corroborates the theory as to the value of a double set of senses, ... the two ears listening to the same sound more thoroughly appreciate its objectivity." This fact is easily verified.

I should, perhaps, refer to Alison's differential stethoscope, which I exhibit. It is a binaural stethoscope, but with a double pectoral extremity. Sounds from two situations are received simultaneously, but from each situation, into one ear. The theory is that the sounds from the two situations can in this way be best compared with each other. The theory is fallacious. If we wish to bring into comparison two sounds which are not musical, or if we wish to compare the quality of two musical notes, we do not desire to listen to both at the same instant, but to each in succession. The increased conduction of sounds by means of a binaural conductor is not obtained by Alison's stethoscope, and a little practice will render it evident that with Cammann's instrument sounds in different situations, listened to consecutively, are much better compared than by the so-called differential stethoscope.

THE NORMAL VESICULAR MURMUR OF RESPIRATION.

Auscultatory sounds, like those obtained by percussion, are to be studied analytically with reference to their differential characters. They are to be studied with special reference to differences in pitch, quality, and intensity; but the other points of distinction which have been mentioned already are to be considered; namely, the duration of respiratory sounds, the rhythmical succession of the sounds of inspiration and expiration, and the apparent nearness to or distance from the ear, especially of vocal sounds. It is needless to say that in the study of auscultation, as of percussion, the analysis of the normal sound should precede and be the point of departure for determining the differential characters of the abnormal sounds which are signs of disease. Entering upon the consideration of respiratory sounds, the normal pulmonary murmur of respiration is to be first considered.

Seeking naturally to give an idea of this murmur by likening it to something familiar, Laennec found no better comparison than to the sound of a person breathing tranquilly in sleep. Feeble as is this comparison, a better has not been suggested. The comparison by Skoda to the sound of air sucked in by the lips, is quite as indefinite. It has been compared to the sound of the wind passing through foliage. This is not an improvement on the comparison by Laennec, except that it has something of a poetic savor. From this comparison the quality of the murmur has sometimes been called breezy. Analyzed with reference to its component characters, the intensity varies so much in different healthy persons that nothing distinctive is to be derived from this source. The pitch, as compared with that of the more important of the morbid respiratory sounds, is low. Here is one distinctive feature. The quality, like that of the normal resonance on percussion, is *sui generis*. It cannot be described by words which give any definite idea of it. It has no close analogy to any other sound produced outside of the body. It can only be correctly appreciated by direct observation. The quality may be called vesicular for the same reason that the quality of the normal resonance on percussion is so called; in each of these normal signs the quality is incident to the vesicular structure of the lungs. This structure is so peculiar that it cannot be fully represented by any artificial contrivance by which the movements of air within the structure may be imitated; hence, the fact that the quality of the respiratory murmur, as well as that of the normal resonance on percussion, is *sui generis*. These characters of pitch and quality relate to the inspiratory sound. The relative characters of the expiratory sound are of importance in distinguishing the normal murmur from certain morbid respiratory signs. The expiratory sound is much shorter than the inspiratory, and also much weaker. It has no vesicular quality. I know of no better way of expressing the quality than by calling it simply blowing. It is not unlike the sound of the expired breath from the open mouth.

Laennec's explanation of the vesicular respiration was that it is due to the friction of the air in the pulmonary alveoli. I need not take time to show that this explanation is unsatisfactory. To say, as does Skoda, that the murmur is due to the resistance which the cells offer to the air, is simply to state a fact without any explanation. Other explanations, alike un-

satisfactory, are, that it is due to contraction of the bronchial muscular fibres in the act of inspiration, as held by Blakiston and Leaning; and, as held by Zamminer and Seitz, that it is produced at the mouths of the infundibula, in the same way as sounds by blowing over the opening of a hollow key. Eichhorst, author of a German treatise on *The Methods of Physical Investigation in Internal Diseases*, (1881), after citing these explanations, assumes that it is a physical impossibility for the respiratory sounds to be produced by the currents of air within the pulmonary air passages, and he considers, therefore, that their source must be within the larynx, being there produced by the projection of the vocal cords, and conducted downward by the air tubes. This is a revival of the doctrine of M. Beau, author of a work on *Auscultation* (1856); an author whose fantastic theories were deemed of sufficient consequence to be always quoted by contemporaneous writers, but almost invariably quoted in order to dissent from them. This glottic theory of the mechanism of the vesicular murmur of respiration is readily disposed of by a very simple experiment. Remove the lungs from the body and separate them from the trachea. Now, if respiration be imitated by means of the bellows, the nozzle being introduced into a primary bronchus, or by means of one of the flexible tubes connected with Davidson's syringe, and the lung be auscultated, either by immediate auscultation or the stethoscope, the vesicular murmur is reproduced, much intensified as compared with the murmur in life. This experiment, assuredly, disproves the physical impossibility of the production of respiratory sounds within the pulmonary air passages, and, consequently, the glottic theory of the production of the vesicular murmur.

For the true explanation (as it seems to me) of the vesicular murmur I am unable to give credit to any writer. In my work on *Physical Exploration*, published in 1856, I submitted the following inquiry: "May not the peculiar quality be owing to the separation of the sides of the cells and the capillary tubes which, to a greater or less extent, come into contact, and, owing to the moisture of the tissues, are slightly adherent during the collapse of the lung incident to expiration?" And I added, "We shall see hereafter that this is the most rational explanation of an important and highly distinctive physical sign of disease." Allusion in the latter sentence was made to the crepitant râle. It is noteworthy that Laennec, in describing the differences between the vesicular murmur and bronchial respiration, says that the latter loses the "slight crepitation" which belongs to the former. The expression "slight crepitation" distinguishes more accurately than any other term the peculiar quality of the vesicular murmur, and, at the same time, it denotes the mechanism. The explanation which, more than a quarter of a century ago, I submitted in the form of an inquiry, I have ever since taught as the true explanation. As corroborative of its truth, I submit the following experiment:

Take the lungs of any animal of sufficient size (a sheep or a calf), twelve or twenty-four hours after the animal has been killed, and introduce the nozzle of a pair of bellows into either the trachea or one of the primary bronchi. Imitate respiratory acts by means of the bellows. If the stethoscope be placed directly upon the lungs, or with a folded napkin intervening, with each inflation a crepitating character of the sound is apparent. The inflation of portions which contained but little or no air, *i. e.*, collapsed portions, gives a perfect representation of the crepitant râle. Now if the intervening folds of cloth between the stethoscope and the chest be sufficiently increased in thickness, the crepitating character is modified, and the quality becomes hyper-vesicular; in other words, we obtain an intensified representation of the vesicular respiration. The lungs from the human body will, of course, answer as well as those of the calf or sheep. The crepitation may disappear after the inflations by means of the bellows have been continued for some time. The expression by Laennec, "slight crepitation," therefore, expresses not only the character of the murmur, but the mechanism of its production.

I refer to an experiment made by Penzoldt, and cited by Eichhorst, in his work[1] on the methods of physical exploration, as exemplifying either the disadvantage of not having studied respiratory sounds analytically with reference to pitch and quality, or the influence of the imagination on the observation of sounds, or, perhaps, of both these two sources of error. It is stated that if a portion of a solid organ, the liver, for example, be placed over the larynx of a healthy subject, the laryngeal respiration is transmitted to the ear of the auscultator without change; but if a portion of inflated lung be so placed, the laryngeal respiration becomes changed, by its transmission, into a vesicular respiration. This latter statement is adduced by that author to show that the vesicular murmur of respiration is not produced within the pulmonary alveoli, but that it is the laryngeal respiration conducted through air vesicles. Let any observer, not biased by theoretical expectations, and familiar with the distinctive characters of the vesicular and the laryngeal respiration as determined by analytical study, repeat this simple experiment, and it will be found that there is no essential difference between the sounds as transmitted through the solid organ and the inflated lung. The inspiratory sound does not lose its tubularity, acquiring in its place the vesicular quality; and the relative pitch of the inspiratory as compared with the expiratory sound, is the same as when the stethoscope is placed immediately upon the integument covering the larynx. I make this statement after having repeatedly made the experiment. Whether this statement or that of Penzoldt is correct, can be readily determined by any one who will take the little trouble requisite for repeating the experiment, and comparing the sounds analytically and impartially.

BRONCHIAL RESPIRATION.

Of the morbid respiratory signs, the one which offers, in its distinctive characters, the strongest contrast to those of the normal vesicular murmur, is the *bronchial respiration*, and there is an advantage, therefore, in considering first this sign. Let me enumerate the distinctive characters of the bronchial respiration, as determined by analytical study, although, doubtless, they are familiar to those whom I now address. The intensity of both the inspiratory and the expiratory sound is often greater than that of the vesicular respiration; but this is not an essential feature. The inspiratory sound has no vesicular quality, but, in place thereof, a quality expressed by the term tubular. It is identical with the sound of a current of air through a tube. The pitch is high. The expiratory sound, usually more intense than the inspiratory, has a tubular instead of the simple blowing quality of the expiratory sound in the normal vesicular respiration; it is higher in pitch than the inspiratory sound; it is prolonged to the length of, or more, of the inspiratory sound, and, instead of being continuous with the latter, as is the case with the inspiratory and the expiratory sound in the normal vesicular respiration, the two sounds are separated by a brief interval of time. The latter char-

[1] Lehrbuch der Physikalischen Untersuchungsmethoden innerer Krankheiten, von Dr. Hermann Eichhorst, Braunschweig, 1881.

acter is due to the fact that the inspiratory sound ceases a little before the cessation of the inspiratory act.

No one doubts that the sign having the characters just enumerated is heard over solidified lung. It occurs, therefore, in the second stage of pneumonia, over lung compressed into a solid mass by the pressure of liquid or air within the pleural space; also, in cases of phthisical exudation and induration, as well as in other affections which solidify the pulmonary structure. That the sign represents exclusively solidification of lung, however, is not universally acknowledged. The opinion is held by many that it represents, also, pulmonary cavities. When I come to consider the cavernous respiration, I shall undertake to demonstrate that this opinion is erroneous. I believe the bronchial respiration to be the respiratory sign of complete or considerable solidification of lung, and of no other morbid physical condition. The only room for doubt as regards this limitation of the significance of the sign, is afforded by cases of dilatation of the intra-pulmonary bronchi. In these cases, as it seems to me, the presence of this sign is due, not to the bronchial dilatation, but to the condensation of lung surrounding the dilated tubes. The artificial illustration of this sign is easy with Davidson's syringe. If the tube conducting from the central bulb be placed close to the ear, and covered with the hand, in order to exclude extraneous noises, the current of air produced by compression of the bulb causes a well-marked tubular sound. A similar sound is heard when the tube conducting to the bulb is placed close to the ear, the sound in this instance being caused by an expansion of the bulb. If we attach to the tube conducting from the central bulb other tubes of more or less length, and varying in size, the tubular sound is heard at any point with an equal force of the current of air, and the pitch is found to be somewhat higher the smaller the size of the tube. Blowing into the tube with the mouth will answer as well as Davidson's syringe; and it is not necessary that the current be strong in order to produce a tubular sound. I oppose this simple experiment to the statement by Eichhorst that it is a physical impossibility for the movement of air in the bronchial tubes to produce a sound. It seems surprising that an author should make this statement when it may be disproved by an experiment which can be made at any moment.

The mechanism of the bronchial respiration, of course, involves the passage of air in tubes; but it is a question in what tubes is the sound produced when this sign is heard over the chest. Laennec's explanation was simple, and, in the main, it has not been disproved. He referred the sound chiefly to the passage of a current of air in the larynx, trachea, and the large bronchi at the root of the lungs. He accounted for the absence of the sign over the healthy chest, first, by the presence of the vesicular murmur, which drowns the bronchial sound; and, second, by supposing that the air vesicles containing air conduct sounds less readily than solidified lung. The better conduction of sounds by solidified lung than by the normal inflated lung was denied by Skoda. Skoda based his denial on physical principles and on certain experiments relating to the conduction of the voice. I shall refer to these experiments in connection with vocal signs. I will simply say here that I have repeated them, and with a result the same as stated by Skoda. Another experiment by Skoda is easily repeated; namely, placing successively over the larynx portions of solidified lung and of inflated lung, equal in volume, and comparing the transmission, through each of these media, of the laryngeal respiration. This experiment shows, according to my observations, that Laennec was in error in supposing that solidified lung is a better conductor of sound than healthy lung. It has been asserted that if a watch be placed alternately beneath portions of solidified and of healthy lung, of equal volume, auscultation shows the solidified lung to be the better conductor of sound. This experiment I have repeatedly made, and with a result the reverse of the assertion that the solidified lung is a better conductor. I may add that up to a recent date I had believed, in accordance with the general belief at the present time, that sounds were better conducted by solidified than by healthy lung containing air.

Laennec supposed that a current of air within the intra-pulmonary bronchi, and even in those of small size, coöperated in producing the bronchial respiration. This supposition has been deemed improbable, at least when an entire lobe is solidified, as in cases of lobar pneumonia. Skoda and others have maintained that a current of air cannot take place within a solidified lobe. This view seems not irrational, considering that the lobe is enlarged to the limit of a full inspiration, that its volume diminishes very little with expiration, and enlarges as little with inspiration, and that the respiratory movements of the chest on the affected side are more or less restricted. Experiment, however, shows that air passes freely through the bronchial tubes within a lobe solidified by pneumonia. In a lung removed from the body, the upper lobe completely solidified and the upper two-thirds of the lower lobe solidified, the unsolidified portion of the lower lobe was readily inflated either by the bellows, or by the breath, the current being inserted either into the trachea or the primary bronchus. Moreover, in the condition just stated, a vesicular respiratory murmur was appreciable over the lower third of the lower lobe during life, as well as by inflation after death, a fact showing the free passage of a current of air within the intra-pulmonary bronchi of the solidified upper two-thirds of the lobe. I assume, therefore, that it is incorrect to say that air does not pass into the bronchial tubes within a lobe which is completely solidified. Assuming this, the question then is, what part does the air in the intra-pulmonary bronchi have in the production of the bronchial respiration? That Laennec was right in supposing a tubular sound to be produced by a current of air in these tubes is not irrational. Such a sound, in fact, may be produced after death by a current of air from the bellows or the mouth directed into the bronchus connected with a solidified lobe.

But there are grounds for attributing the bronchial respiration, chiefly, if not exclusively, to the larynx and trachea. The fact that in essential characters relating to pitch and quality, the normal laryngeal and the tracheal respiration are identical with those of the bronchial respiration, is perhaps sufficient in itself to prove that the latter is in reality the former conducted into the solidified lung. How can this be, if solidified lung be not a good conductor of sound? The answer to this question is, the conduction is not by the solidified lung, but by air within the intra-pulmonary bronchi. This, as it seems to me, enters into the explanation of the bronchial respiration. The air in the intra-pulmonary bronchi is the conducting medium, as it is in the stethoscope. The explanation does not conflict with the fact that solidified lung is a poorer conductor of sound than healthy lung. For good conduction of sound it is not necessary that the conducting column of air be large. The space containing air within the tubes of the binaural stethoscope, is not larger than that in the medium sized bronchi. The explanation is consistent with the absence of bronchial respiration when the bronchial tubes are obstructed by either an accumulation of morbid products, or by pressure from without. The following experiment illustrates the conduction by the air within the intra-pulmo-

nary bronchi: In a lung from a body dead with acute pneumonia, the upper lobe was completely solidified. When a current of air from the mouth was directed into the trachea, and the stethoscope applied to the solidified lobe, a well-marked bronchial respiration was appreciable. By compressing with the fingers the bronchus leading to the solidified lobe, a very feeble and distinct respiratory sound only was perceived. A well-marked bronchial respiration returned when the compression was suspended. Dr. Powell, of London, cites an experiment made by MM. Boudet and Chaveau, as demonstrating the conduction from the larynx and trachea of the bronchial respiration. On a horse affected with pneumonia, well-marked bronchial respiration over the solidified lung was ascertained. Tracheotomy was then performed, and when the wound in the trachea was held widely open, the bronchial respiration disappeared, while exaggerated vesicular respiration over the other lung continued. On introducing a tube within the wound the bronchial respiration over the solidified lung returned. This experiment illustrates not only the fact of the conduction from the larynx and the trachea, but also that the conducting medium is the air within the bronchial tubes.

Experimental observations thus appear to prove conclusively that suppression of the vesicular murmur and conduction of the tracheal and laryngeal respiration are the two factors in the mechanism of bronchial respiration, admitting that solidification does not render the lung a better conductor of sound. This admission, however, will be found to be not easily accorded with certain clinical facts. To some of these reference will be made in connection with vocal signs. One difficulty relates to bronchial respiration. If lung containing air within the alveoli be a better conductor of sound than solidified lung, why is it that we do not have bronchial respiration when the vesicular murmur is suppressed by emphysema? Here is an evident inconsistency. If, however, the explanation which has been given of the bronchial respiration be proven, it is not disproved by apparently conflicting facts. The proper course to pursue is to seek to reconcile these with the explanation. I am not prepared to say how this is to be done in the instance just cited.

The higher pitch of the expiratory, as compared with the inspiratory, sound in the bronchial respiration accords with what is observed when the stethoscope is placed upon the larynx or trachea. The explanation is the narrowed orifice at the glottis by an approximation of the vocal cords in the act of expiration, when compared with the separation of the cords which takes place in the inspiratory act.

CAVERNOUS RESPIRATION.

From the bronchial I pass to the *cavernous respiration*. Laennec recognized the existence of a cavernous respiration, but he regards it as having the same characters as the bronchial respiration, its distinctive feature being a perception as if the air entered a space larger than that of the bronchial tubes. He described two modifications, in one the air seeming to enter and emerge from the ear of the auscultator, and in the other the sound giving the idea of a movable veil between the cavity and the ear. He called the former of these modifications, a blowing respiration, and the latter veiled blowing. It must be admitted that Laennec's account of cavernous respiration is indefinite and unsatisfactory. The criticisms of Skoda are undoubtedly just. But Skoda fell into an error greater than that of Laennec, with regard to this sign, for he denied *in toto* the existence of a cavernous, as distinct from bronchial respiration. He says (quoting his language), "I consider Laennec's bronchial and cavernous respiration to be one and the same murmur; his blowing bronchial to be a loud bronchial murmur, and his *souffle voilé* to be an unimportant modification of the bronchial respiration." So great has been the influence of Skoda's teachings, that the most recent German writers hold to the identity of the characters of the bronchial and the cavernous respiration. The individuality of cavernous respiration has been, and is acknowledged by English and French authors, but its differential characters were not distinctly indicated prior to 1852. I believe that I do not assume too much in saying that these characters were first fully pointed out in the prize essay published in that year, to which I have already referred, and in my work on *Physical Exploration*, published in 1856. My description of cavernous respiration was based on the analytical study of respiratory sounds with reference to pitch and quality, conjoined with autopsical examinations. In the instances given in my essay, the examinations after death were made, and written reports furnished, by Prof. John C. Dalton.

With reference to its distinctive characters, the cavernous respiration is to be contrasted, on the one hand, with the bronchial respiration, and, on the other hand, with the normal vesicular murmur. Contrasted with the bronchial respiration, the points of difference are not less marked than those which distinguish the bronchial respiration and the normal vesicular murmur. The cavernous inspiratory sound has no tubular quality, and is low in pitch; the expiratory sound is usually more feeble than the inspiratory, its duration or length variable, and its pitch is lower. With an appreciation of these differential characters, the cavernous and the bronchial respiration cannot possibly be confounded. The quality of the sound in both the cavernous inspiratory and expiratory sound may be called blowing, in distinction from a tubular quality. The quality is like that of the expiratory sound in the normal vesicular murmur. The contrast of the cavernous respiration with the normal vesicular murmur is less strong than with bronchial respiration. In both the cavernous respiration and the normal vesicular murmur, the pitch of the inspiratory and of the expiratory sound is low, and the expiratory is lower in pitch than the inspiratory sound. The essential point of difference relates to quality. The vesicular quality is wanting in the cavernous respiration. Given a respiratory sign in which the inspiration is non-vesicular and non-tubular, with lowness of pitch, the expiration having the same quality but still lower in pitch, the sign can be no other than cavernous respiration. In confirmation of the presence of this sign, clinically, circumstances other than its distinctive characters may be taken into account. It is limited to a circumscribed space; around this space the respiratory sound is either vesicular or the signs of more or less consolidation are present, the latter being true in a large proportion of instances; the coexisting vocal signs and those obtained by percussion are indicative of cavity, and evidence is sometimes obtained by inspection.

Artificially the cavernous respiration may be illustrated by the following simple experiment: The cavity is represented by an India-rubber balloon of the size of a large orange, with thin walls, and two openings connected with a tube of greater or less length. Attaching to one of the tubes a pair of bellows, or, what answers equally well, using the breath from the mouth, the balloon is inflated and the air withdrawn in imitation of the respiratory acts. Placing a binaural stethoscope over the balloon, or listening with it close to the ear, the movement of the air into it and out of it gives rise to a low-pitched blowing sound, the outward lower in pitch than the inward current. These observations, identical with those of the cavernous respiration, may

be contrasted with tubular breathing produced artificially in the manner already stated.[1]

The sign may also be reproduced within a cavity with flaccid walls in a lung removed from the body. I had recently under observation a hospital case in which there was well-marked cavernous respiration at the summit of the chest. After death, in that situation was found a cavity of the size of a large orange, the anterior wall of which consisted of only thickened pleura, and collapsed when the lung was removed from the body. The cavity was readily and largely inflated by the breath directed into the trachea. With the stethoscope applied upon the lung, over the cavity, a loud, low-pitched, blowing sound was perceived when the air entered and when it escaped from the cavity. It is not difficult for those connected with large hospitals to obtain this demonstration of the distinctive characters of the cavernous respiration.

AMPHORIC RESPIRATION.

Amphoric respiration is to be regarded as a variety of the cavernous, and claims but a few words. As is well known, it is a sign *par excellence* of perforation of lung and pneumothorax; but it is not a very infrequent sign of a pulmonary cavity. Whenever present, if pneumothorax be excluded, it is diagnostic proof of a cavity with rigid walls, that is, walls which do not expand notably with inspiration, and collapse with expiration. As produced in cases of pneumothorax, it may be represented artificially by blowing through a small tube into an inflated India-rubber bag of considerable size. As produced in a pulmonary cavity, it is represented by directing a current of air from the mouth or a pair of bellows over the opening into an India-rubber ball of the size of an egg or an orange. It may be demonstrated to be a sign of a cavity with rigid walls in a lung removed from the body. In the specimen just referred to, of a cavity with flaccid walls, which furnished a cavernous respiration after death and during life, a little below this cavity the lung was solidified; but within a circumscribed space well-marked amphoric respiration was perceived when a current of air from the mouth was directed into the lung. An incision revealed a cavity of about the size of an English walnut, surrounded on all sides by solidified lung.

BRONCHO-VESICULAR RESPIRATION.

The three signs which have been considered, namely, the normal vesicular murmur, the bronchial respiration, and the cavernous respiration (the first of these, a normal sign, and the two others abnormal signs), may be said to constitute the simple types of the respiratory sounds heard over the chest. Other signs consist of the characters of these in combination, and may, therefore, be distinguished as compound types. Of these signs, the one which is of most importance I shall consider under the name *broncho vesicular respiration*. This name was proposed in my work on *Physical Exploration*, published in 1856. It has been adopted, to some extent, by writers in this country. Prof. Da Costa prefers the term *vesiculo-bronchial*. The pressing need of a term expressive of certain morbid auscultatory sounds must, as it seems to me, be evident to any one who has given attention to the study of these sounds. The morbid physical conditions represented by the sounds referred to are the varying degrees of solidification of lung, falling short of a degree sufficient to give rise to a purely bronchial respiration. In a purely bronchial respiration, the inspiratory sound is devoid of any vesicular quality; the quality is entirely tubular. In the broncho-vesicular respiration, the inspiratory sound is both tubular and vesicular; that is, it consists of these two qualities combined. The tubular and the vesicular quality may be combined in different proportions; in some instances the vesicular, and in other instances the tubular, quality predominates. The predominance of the one or of the other of these qualities depends on the degree of solidification; if the solidification be but slight, the vesicular quality exceeds the tubular, and, *per contra*, if the solidification be nearly sufficient for the purely bronchial respiration, there is but little of the vesicular quality, the tubular being in excess. The broncho-vesicular respiration, thus, as a representative sign, covers all the modifications of respiratory sounds, denoting solidification, between the normal vesicular murmur and a purely bronchial respiration. And by means of this sign it is practicable, not only to recognize the existence of solidification which is insufficient in degree to give rise to the bronchial respiration, but to judge of the degree of solidification, that is, whether it be very slight, slight, moderate, or closely approximating to that requisite for a purely bronchial respiration. The combination of the vesicular and the tubular qualities carries with it other characters which correspond to the different proportions in which the two qualities are combined. In proportion as the vesicular quality predominates in the sound of inspiration, the pitch of the sound is low; and, conversely, the pitch is raised in proportion as the tubular quality predominates. The expiratory sound is prolonged, high in pitch, and tubular in quality, in proportion as the inspiratory sound is high in pitch and tubular in quality; in other words, in proportion to the degree of solidification; and, conversely, the expiratory sound is less prolonged, less high, and less tubular in proportion as the vesicular quality in the inspiratory sound predominates; in other words, in proportion as the degree of solidification is small.

The name broncho-vesicular is intended to supersede such terms as rude, rough, and harsh respiration. These terms are not only inappropriate, but they lead to error. An exaggerated vesicular respiration without solidification of lung may be ruder or more harsh than the sound which represents the latter condition. An imperfectly developed dry bronchial râle may give roughness to the respiratory murmur. These terms, thus, do not denote any fixed, definite, morbid physical condition, and erroneous inferences are liable to be drawn from them in cases of disease. Still more unsatisfactory is the name *indeterminate respiratory murmurs* introduced by Skoda, which embraces the abnormal sounds expressed by the term broncho-vesicular. Under the name indeterminate Skoda includes, quoting his language, "Respiratory murmurs having neither the character of vesicular nor of bronchial respiration." He admits that "No distinct indication can in any particular case be drawn from such a murmur," and he adds, "All respiratory murmurs which give us no information as to the state of the parenchyma of the lungs I call indeterminate respiratory murmurs, and any subdivision of them appears to me to be useless." The name "indeterminate" with the meaning as defined by Skoda, is still in vogue with German writers. The name is applied to sounds due to simple bronchitis, as well as to phthisis and other affections. It must be sufficiently obvious that with the confused idea of the sign, a confusion implied in the name "indeterminate," it cannot be of much practical value in diagnosis. It is far otherwise with the broncho-vesicular respiration, its characters having been determined by analytical study. The sign is of great practical value in the diagnosis of phthisis, in

[1] The sign is not produced by blowing into a balloon with but one opening. I infer, therefore, that for the cavernous respiration in life, cavities must have openings for the exit as well as the ingress of air.

the early stage of pneumonia, and the stage of resolution, and in other pulmonary affections involving partial solidification of lung. The sign represents the latter condition, and nothing else. It cannot be produced by a simple bronchial affection. It is not less determinate as regards its distinctive characters and its pathological significance, than any of the respiratory signs.

A case of pneumonia during the stage of resolution affords illustrations of all the gradations of this sign. The sign is present as soon as absorption has removed the contents of a sufficient number of air vesicles for a vesicular quality to be perceived in the sound of inspiration. The tubular quality now predominates, and the respiratory sound is still prolonged, high, and tubular. With each successive day, as absorption progresses, the vesicular quality in the inspiratory sound increases, and the tubular quality diminishes. With these changes in the inspiratory sound, the expiratory sound on each successive day is less prolonged, less intense, less high in pitch, and less tubular in quality. At length, resolution being complete, the vesicular quality becomes, for a time, more marked than in health, all the characters of the broncho-vesicular respiration having disappeared.

The characters of the broncho-vesicular respiration may be studied as illustrated in the healthy chest. In the infra-clavicular region, especially the sternal portion, and in the interscapular region, the respiratory murmur, as compared with that over other parts of the chest, is broncho-vesicular; that is, owing to the proximity of the larger bronchi, the characters of the bronchial and of the vesicular respiration are combined. This is more apparent on the right than on the left side. The respiration in these situations has been called the *normal bronchial respiration*. This expression is inexact, inasmuch as the respiratory sounds are not purely bronchial. It is more correct to say that in these situations there is a *normal broncho-vesicular respiration*. This normal broncho-vesicular respiration may be still better observed by auscultation of the lungs removed from the chest. With the human lungs or those of the calf or sheep, if the nozzle of a pair of bellows be introduced into the trachea, the respiratory acts imitated, and the stethoscope placed either on the lung, or a thin layer of cloth only interposed, the mixture of the characters of the bronchial and the vesicular respiration at and near the apex of the lungs, will be rendered very marked by contrast with the respiratory sounds over other portions.

BRONCHO-CAVERNOUS RESPIRATION.

The combination of the characters of the bronchial with those of the cavernous respiration, and of the cavernous with the vesicular murmur, constitute other compound types. Seitz, the editor of the later editions of Niemeyer's work on the *Practice of Medicine*, has described a respiratory sign which he calls a "*metamorphosizing respiratory sound*." The metamorphosis is in the inspiratory sound. The sound at its beginning is described as rude, and the last two-thirds as bronchial. Bearing in mind that with German writers there is no cavernous, as distinguished from bronchial, respiration, I infer the latter part of the respiratory sound to be cavernous. Such a metamorphosis was described by me in my prize essay, published in 1852, together with the physical conditions found after death. This is one variety of a broncho-cavernous respiration. The first part of the inspiratory sound is a bronchial respiration. It takes place before the air has entered freely into a cavity. One of the characters of the cavernous inspiration is that it is evolved slowly. When the air enters freely into the cavity, the bronchial is superseded by the cavernous respiration. The sign thus denotes a cavity, with proximate solidification of lung. Another variety is an association of a bronchial expiration with a cavernous inspiration. This variety is not infrequently met with. The explanation is simple. In bronchial respiration, the expiratory sound, as a rule, is more intense than the inspiratory. The inspiratory sound may be relatively quite feeble, and it is sometimes wanting. On the other hand, the expiratory sound in cavernous respiration, as a rule, is feeble, and may be quite so, or it may be wanting. Now, it is easy to understand that when a cavity is situated near a portion of solidified lung, the auscultator may obtain over the cavity an inspiratory sound which is cavernous, that is, low in pitch and blowing in quality, associated with an expiratory sound which is bronchial, that is, high in pitch and tubular in quality.

VESICULO-CAVERNOUS RESPIRATION.

The characters of the vesicular and of the bronchial respiration are combined when the pulmonary structure surrounding a cavity remains intact, or but little affected. The vesicular quality is then derived from the surrounding lung. The recognition of this compound type may seem a refinement in auscultation, but that in certain cases it is readily recognized, clinically, I am well satisfied. It may be called a *vesiculo-cavernous respiration*.

DIMINISHED AND SUPPRESSED VESICULAR MURMUR, AND INTERRUPTED RESPIRATION.

Diminished vesicular murmur, without change in pitch and quality, and suppression of the murmur, which are physical signs of much value, taken in connection with other signs and with symptoms, do not here claim consideration. Of the sign called interrupted, wavy, and cog-wheeled respiration, I will only remark that, as an isolated sign, it has but little clinical importance; it derives whatever value belongs to it from its association with other signs. I shall conclude this discourse with some remarks on prolonged expiratory sound, either existing without an inspiratory sound, or when the latter is too weak in its character to be distinctly appreciable.

PROLONGED EXPIRATION.

It is remarkable that Laennec should have given so little attention to the study of the sound of expiration. James Jackson, the younger, was the first to appreciate the clinical value of a prolonged expiratory sound. As early as 1832 he called attention to the significance of a prolonged expiratory sound at the summit of the chest in the diagnosis of pulmonary phthisis. He noticed not only the prolongation, but its resemblance in character to the prolonged expiration in bronchial respiration. Since his observations this sign has been included in the group of signs to be sought after in the diagnosis of phthisis. It may or may not have significance in relation to that disease. A prolonged expiration which may be more or less high in pitch and tubular in quality, is not very infrequently observed in healthy subjects at the summit of the chest on the right side. It belongs to the normal broncho-vesicular respiration, and may be present when the characters of this sign, owing to feebleness of the inspiratory sound, are not appreciable. I have known a prolonged high-pitched expiration to exist on both sides at the summit of the chest, no other morbid signs being therewith associated. Absence of other signs of disease is the fact to be relied upon in judging that the prolonged expiration is a normal peculiarity. But, as a morbid sign, prolongation of the expiratory sound is not always evidence of phthisis nor of any affection involving solidification of lung. It is a sign in cases of pulmonary emphysema, and may occur whenever the expiratory act is increased in force and length, or whenever

there is an obstacle to the free exit of air from the smaller to the larger bronchial tubes. How is this difference in the significance of the sign to be recognized clinically? This question can be definitely answered. If the prolonged expiratory sound be high in pitch and tubular in quality, exclusive of the instances in which it has these characters as a normal peculiarity at the summit of the chest on the right side, the sign denotes lung solidified by a phthisical or some other solidifying morbid process. It has precisely the same significance as when it is associated with a high-pitched tubular inspiratory sound in the bronchial respiration. If, on the other hand, the prolonged expiratory sound have characters, as regards pitch and quality, the same as in the normal vesicular murmur, differing only in length and intensity, it is not a sign of phthisis, nor of any other affection involving solidification of lung. This variety of prolonged expiratory sound, associated with other signs, is diagnostic of pulmonary emphysema.

These differential characters pertaining to the sign, the difference in its significance being correspondingly marked, exemplify the importance of the analytical study of auscultatory phenomena. With few exceptions in works treating of auscultation at the present time, a prolonged expiratory sound, as a morbid sign, is considered without reference to the differences in pitch and quality on which depend its diagnostic significance. If these differences be not taken into account, the sign is as likely to lead to error as to a correct diagnosis.

ORIGINAL ARTICLES.

AMPUTATIONS, AND THEIR ANTISEPTIC DRESSINGS.

BY J. HENRY C. SIMES, M.D.,
ASSISTANT SURGEON TO THE EPISCOPAL HOSPITAL, PHILADELPHIA.

ANY experience in any method of treatment, whether the result proves favorable or unfavorable, is, if carefully noted, a means of assisting the treatment in similar cases which may occur at a future period. More especially is this a fact when applied to those methods which from their novelty or theoretical claims are urged by their discoverers.

Antiseptic surgery, at the present time, can scarcely be considered as a new method of treatment in surgical operations, nor are its claims now based entirely upon theoretical grounds; yet it is far from being accepted as a general method of treatment; more particularly is this true of American surgeons. In this city I know of no hospital in which its surgeons have fully and thoroughly carried out the details necessary to give their treatment the name of antiseptic; that is to say, they have not attended to the minute directions, and in many cases the principal features have been omitted in their operations. For these reasons I have thought a brief outline of my experience, during the past summer while on duty at the Episcopal Hospital, would perhaps aid in assisting to form some conclusions as to the value of antiseptic dressings when applied to amputations.

My reasons for not continuing the usual mode of treatment, viz., non-antiseptic, and adopting the antiseptic, was that upon beginning my term of service it was found that there had been for the previous spring and winter months, an almost uninterrupted series of secondary complications (erysipelas, cellulitis, etc.) following the amputations which had been performed in the hospital; these complications were not limited to this hospital alone, but upon further investigation it was ascertained that in most of the hospitals throughout the city, similar sequelæ to operations had prevailed. Therefore, it seemed to me a change of some kind was justifiable, in order to endeavor to check the unfavorable course taken by the process of healing after amputations. The antiseptic dressing had not been, during this year, employed in the hospital. The opportunity to test its usefulness or not, as the case might be, here presented itself, and a trial was determined upon.

The procedure followed, in the cases coming under my care, was essentially that recommended by Lister, and consisted, in outline, of the carbolized spray; catgut ligatures; close apposition of the wound by means of silver sutures; thorough drainage, obtained by the use of rubber drainage-tubes of large calibre (one-fourth of an inch); washing the wound with carbolized water; oil-silk protective over the line of incision; carbolized gauze wet with carbolized water; dry carbolized gauze; rubber cloth, which was securely kept in close relation to the parts by the employment of a narrow elastic bandage at its margin; and, finally, the whole held in position by a muslin roller. The instruments used during the operation were placed in a tray of carbolized water.

The results obtained by the employment of the above dressing were very satisfactory, as may be seen from the following cases. These cases, seven in number, are not given in full, but they may be summarized by stating that they consisted of two amputations of the forearm, two amputations of the arm, one amputation at the knee-joint, one resection of the knee, and one amputation of the female breast. In none of the cases was there any secondary complication, no erysipelas, no cellulitis, no abscess. Certainly here was a change for the better, since only a month previous one or all these complications accompanied similar operations, and the questions which naturally presented themselves were: Was the favorable change owing to a change in the manner of dressing? Was it due to a change in the time of the year? or, Was it dependent upon any other outside influence?

These were all very satisfactorily answered to my mind, and convinced me that there was but one cause to account for the results which so very markedly differed from those previously obtained. The, to me, convincing circumstance exists in the progress of other operations performed in the same hospital, at the same time and treated in the same wards, but under a different method of treatment; the dressing was not antiseptic, and the results were not so favorable. These cases were one amputation of the forearm, three amputations of fingers, one amputation of thumb, and one amputation of toe. In all of the above cases there occurred either a complication of erysipelas, cellulitis, abscesses, or all three. When contrasted with the former cases—those dressed antiseptically, there are observed very evi-

dent and important differences. Here are two series of cases, both placed under the same surrounding influences, both receiving the same care and attention, yet each following a different course. A cause for such a distinct and marked difference in the course of the two series is to be expected and naturally sought after, and the only appreciable one is found in the different methods employed in dressing the cases. In nothing was there any known variation made in treating the two series, except in that of the different dressings—the one antiseptic, the other not; and it would seem only reasonable to conclude that this difference was the one which influenced the ultimate results.

Not only were these differences of secondary complications following the operations noticeable, but there was also a great variation in the symptoms which followed as a result of operative interference; and when comparing the two series one with another, it was found that the cases dressed antiseptically presented a much more favorable record than those cases in which this method of treatment had not been employed.

A symptom common to both series, but one in which the difference was most decidedly marked, was that of *pain*. In the cases in which the non-antiseptic dressing was used this symptom was always present, and habitually demanded anodynes for its relief; while, on the contrary, with the antiseptically dressed cases, the pain was so slight—indeed it may be said absent—that in none were anodynes indicated, and their administration was omitted during treatment.

The amount of *traumatic fever*, in the two series of cases, differed in a very appreciable degree. In the cases in which the antiseptic dressing was used, this symptom was generally very poorly defined, and its presence only indicated by the employment of the thermometer; while in the non-antiseptic dressed cases, there was no exception: each case had a distinct and quite evident attack of surgical fever. This variation in the relative amount of fever was very apparent when the temperature records taken during the progress of healing of the wounds were contrasted. Thus, the average maximum temperature in the antiseptic dressed cases was 99 6° Fahr., while in the non-antiseptic it was 102.5° Fahr.

The *aspect* of the wounds in the two series of cases was very different. The cases in which the antiseptic dressing was used presented a perfectly normal appearance of the surrounding parts; there was an entire absence of all redness and tumefaction, only a very faint red blush was observed along the line of incision and surrounding the punctures produced by the wire sutures. In the cases not treated antiseptically, there were seen, on the contrary, a marked diffused redness and considerable œdema of the neighboring tissues.

The symptom of *tenderness* upon pressure, in the two category of cases, was singularly unlike. In the one—the antiseptic dressed, it was so slight as scarcely to merit a place as a symptom; while in the other it was a very prominent and always present feature.

The *length of time* necessary to complete the healing of the wounds in the two series of cases varied very much. Those cases in which the antiseptic dressing was used healed much sooner than those in which it was not. This circumstance was, undoubtedly due to the secondary complications which interfered with the process of healing in the latter cases.

There is one point more I wish to speak of, and it is in reference to the application of the antiseptic dressing. In reading over the directions given by the advocates of this method of treatment, it does appear a very formidable and extremely tedious one. But in its practical application, however, I am quite satisfied, from my experience with it, that these seeming drawbacks to its use do not exist. It is something out of the usual routine, and the first trials made with it may, and indeed do, call for a little more time and attention on the part of the surgeon; yet with a little experience, and the assistants and nurses becoming familiar with its application, the dressing can be applied with as great facility as that ordinarily employed. A circumstance not to be overlooked, and it also bears upon the question of time occupied in applying this method of treatment, is that the renewal of this dressing is not required as often as the non-antiseptic. Most of the cases which were dressed antiseptically had the dressing renewed two or three times in the course of a week, frequently the interval was longer —once in four or five days. In the non-antiseptic dressed cases, it was generally necessary to renew the dressings daily, and they never remained longer than two days without renewal. Therefore, it is seen that the time actually occupied in dressing these two series of cases was much longer in the non-antiseptic than in the antiseptic.

TOTAL LOSS, BY SLOUGHING, OF BOTH PAROTID GLANDS.

BY C. M. RAMSDELL, A.M., M.D.,
OF LAMPASAS, TEXAS.

ON the 26th of August, 1882, my brother, Dr. F. R. Ramsdell, was called into the country to see a case of fever. The patient was Mr. Lewis C., white, carpenter, æt. 29, native of Michigan; height, 5 ft. 11 in.; weight, 150 pounds; family history, consumption on the side of the father, whom he resembles. For several weeks he had been working among the cedar brakes on the Colorado river, where he contracted chills and fever, which soon compelled him to quit work.

When seen, Aug. 26th, he was delirious, very restless, with marked opisthotonos, and complained of constant and severe pain in the back part of the head and neck. His temperature in the axilla was 106° F., pulse 120, resp. 32, spasmodic. He was given potassii brom. gr. x, tr. aconit. gtt. iij, spt. æth. nit. f3ss, every two hours until fever abated; then cinchonia alkaloid gr. xx, in four doses, one to be taken every four hours. On the following day I saw the patient, and from that time on the case was treated by my brother and myself in company.

During the night of the 26th, the fever left him

and returned on the afternoon of the 27th; the temperature reached 105°, but there was no opisthotonos and but little delirium. The urine was scanty and very dark, coffee-colored, and much pain was felt in the lumbar region. He was given spt. æth. nit. a teaspoonful every three hours for two days, and the same amount every six hours for several days longer, the urine gradually becoming normal in quantity and color. During the night of the 27th he took quinine gr. xxx, with pulv. doveri gr. x.

There was no return of the fever, but the patient was greatly prostrated so that he could scarcely sit up in bed. He was stupid, and talked incoherently much of the time during the 28th, still complaining of pain in the head. On the morning of the 29th his left jaw began to swell, and by noon the whole left side of the face and neck was much swollen and very painful, especially in the parotid region. There was also intense pain in the left ear, and the patient was continually turning from side to side and crying out. Morphine in doses of gr. ¾ to gr. j, every four hours, and local applications of vinegar and hot fomentations, gave only slight relief. On the 30th, the right parotid region became inflamed, and the swelling on that side was soon as great as on the left, reaching an enormous extent on both sides, extending down the neck to the shoulders and backwards beyond the mastoid region, so that the auricles were thrust upwards and forwards, giving a very grotesque appearance to the sufferer's countenance.

The prostration was so great, and the rigidity of the jaws such, that food was administered with difficulty. He was given half an ounce of brandy in egg-nog or milk-punch every two hours for three days, and at longer intervals, alternating with animal broths, for about two weeks. Quinine gr. v was also given night and morning from Aug. 28 to Sept. 8. His tongue was enlarged and heavily coated, mouth very dry, and hearing much impaired. On Sept. 1st there was a discharge of thin, ichorous pus from the left meatus auditorius externus. On the 2d, a similar discharge took place from the right, and fluctuation was noticeable just back of the lobe of each ear. He also had a slight chill, and night sweats set in, for which he was given 20 drops of aromatic sulphuric acid three times a day for four days.

On Sept. 3d, the abscess on the left side was lanced at a point half an inch below and behind the lobe of the ear, and the day following that on the right was opened at a corresponding point, in both cases giving exit to a large quantity—an ounce or more—of thick yellow pus mixed with a substance resembling the white of egg. From this time on the pain was much less severe, and the morphine was discontinued, but, as the patient kept calling for it at frequent intervals, to pacify him a number of powders were made out, consisting only of wheat flour, labelled "morphine," and after taking one of these he always seemed to be greatly relieved. His bowels were inclined to be constipated, but an action was procured about once in two days by the use of small doses of sulphate of magnesia.

On the 8th, he was put upon the following tonic which he continued to use for three weeks.

℞.—Tr. nucis vomicæ, . . . fʒiiss.
Tr. cinchonæ, . . q. s. ad. fʒiv.—M.
S. A teaspoonful four times a day after eating.

An attempt was made to apply compresses to the sides of the neck in order to secure thorough evacuation of the abscesses and prevent burrowing of the pus, but the patient would not tolerate any kind of dressing, pulling them off as fast as they could be applied.

On the morning of the 10th, the openings made by the lancet, which had become considerably enlarged by sloughing, were found occluded by what the attendants thought to be "proud flesh." This was removed by pulling it out with forceps, and was found to be the parotid glands almost entire, the superficial portions having sloughed away so that only a few fibres of tissue held them in place. The left gland came out easily, the right required a little cutting to detach it from its connections. Both presented a similiar appearance, being somewhat spongy and having deep sulci, apparently where large bloodvessels or nerve-trunks had passed through their substance, and the right gland still showed something like the outlines of the natural shape, but the left was not larger than the first joint of the thumb, and its true character could be made out only by its position and its internal structure.

After the removal of the glands as much as three fluidounces of thick pus escaped from each cavity. There was no hemorrhage nor has there been any paralysis, so that no important nerves or bloodvessels could have been involved. No other glands were implicated nor was there any burrowing of pus. The discharge from the ears ceased in a few days after the glands came away, the only treatment directed to them having been a daily syringing out with warm water.

On September 13th, he was given sixty granules containing one-tenth of a grain of calcium sulphide each, of which he took three per diem until all were used. He recovered strength slowly, the wounds remaining open until about the middle of October.

By the 10th of November he was entirely well, except slight stiffness of the jaws. He then complained of having more "heart-burn" than he used to have, and said that his mouth seemed dryer than natural. A careful examination with a fine probe showed Steno's duct to be entirely closed on the left side, and to consist only of a *cul-de-sac* about one-fourth of an inch deep on the right.

At the present time, November 25th, his gastric trouble has disappeared and his mouth has regained its natural amount of moisture, doubtless through an increased activity in the remaining salivary glands. The loss of the parotid glands has caused no deformity beyond a slight depression and cicatrix at the site of the openings made by the lancet. The hearing is normal.

This case seems to be unique. Flint, *Practice of Medicine*, p. 401, says that parotiditis is an occasional complication of typhus and typhoid fever, and that in such cases considerable sloughing of the

areolar tissue frequently occurs, but neither he nor any other writer, so far as I know, mentions loss of the gland as a possible result.

MEDICAL PROGRESS.

CUTANEOUS MANIFESTATIONS OF MALARIA.—PROF. VERNEUIL and DR. A. MERKLEN give the following conclusions in a paper with the above title:

1. Herpes is a frequent manifestation of malaria.

2. It may precede the access of the intermittent fever, occur during any one of the three stages of the attack, or after the sweat. There is consequently no etiological correlation between herpes and the fever, in spite of their frequent coincidence.

3. Malarial herpes possesses no special characteristics. Its most frequent seat of occurrence is on the face, and while usually discrete, it may occasionally become confluent.

4. The black crusts and vesicles of herpes are associated with the grave and pernicious forms of malarial fever.

5. Exceptionally, malarial herpes occurs under the form of zona.

6. In all forms, malarial herpes may be preceded or accompanied by vaso-motor troubles, disturbances of the sensibility of the skin in its neighborhood, and may perhaps indicate a nervous origin of the complication.—*Ann. de Dermatol. et de Syphitog.*, November 25, 1882.

THE COMPLICATION OF LABOR WITH OVARIAN TUMORS.—DR. R. LOMER, of Leipzig, contributes a paper on the above subject to a recent number of the *Archiv für Gynäkologie*. His conclusions are based upon the collections of cases made by Playfair and by Jetter. We shall only quote those which relate to treatment. But we may remark, first, that the tumors in the cases in question are always small, for the reason that large tumors are commonly found out before labor begins; and it is obvious that only a tumor small enough to be contained in the pelvic cavity can obstruct labor. Dr. Lomer's first practical rule is one of which the wisdom is obvious. It is, that in labors complicated with ovarian tumor, interference should not be too long delayed. 2. In all cases an attempt should be made to push the tumor out of the way, above the pelvic brim. 3. If this cannot be done, the puncture of the cyst should be the next alternative. 4. Should the contents of the tumor be too viscid to flow through a canula, a free incision should be made into the cyst-wall. Dr. Lomer remarks that from this measure to the pulling down of the cyst, ligature of its pedicle, and removal of the tumor—that is, vaginal ovariotomy—would seem but a step. Nevertheless, the latter operation has never yet been done, lack of time usually having been a sufficient obstacle. When the cyst has once been emptied, vigorous pains have forced down the child, and so put a stop to the operator's further proceedings. 5. All further attempts at emptying the tumor are dangerous, and should not be attempted. 6. When the tumor can neither be pushed up nor diminished in size, the choice must be made, according to the peculiarities of each case, between perforation and Cæsarean section.—*Medical Times and Gazette*, December 16, 1882.

A DOUBLE SUPERIOR VENA CAVA.—DR. H. REX reports such a case in which the right superior vena cava was formed by the union of the right common jugular and axillary vein, and was joined at the angle of union of these two vessels by the right vertebral vein. It passed in front of the trunk of the innominate artery and pulmonary vessels into the right auricle. The left superior vena cava could clearly be separated into a vertical and a horizontal portion; the vertical portion was formed by the union of the left common jugular, axillary, and vertebral veins, and passed backwards in front of the carotid and subclavian arteries, and in front of the ligamentum arteriosum and pulmonary vessels to the left side to reach a position behind the left auricle. The transverse portion was then bent on itself in the left auriculo-ventricular furrow, and entered the right auricle below the left pulmonary veins.—*Centralbl. f. die med. Wissen.*, November 18, 1882.

CHOREA AND RHEUMATISM.—DR. THOMAS R. FRAZER, F.R.S., narrates a case of chorea which shows in a most marked manner the relations between chorea and rheumatism. This relationship has long been recognized. First referred to by Bouteille and Berndt, it was afterwards acknowledged by Copland, Scudamore, Abercrombie, and more recently stated in the exact form of statistical enumeration by Hughes, Kirkes, Sée, Roger, and many other physicians. Its existence is now generally admitted, although occasionally it is regarded as a mere coincidence, the relationship being relegated even to the trivial bond which connects any depressing agent with the production of a disease. A case such as that which he at this time described, undoubtedly affords very strong support in favor of a causal relationship. It affords supports from two aspects of the case—from its time of occurrence, and from the results of the treatment. The former is so significant, in the first occurrence of the choreic disease as well as in its subsequent appearance during a relapse of the rheumatic fever, that it is impossible to overlook it. The latter has, in addition to its equally clear significance, the further value that it constitutes a description of evidence, the quantity of which, so far as he knew, was very limited. He referred for evidence of probably a similar description to the fact that some cases of chorea have been treated with success by Dr. Weir Mitchell and Dresch with the same remedy that produced such striking results in his patient. The details of these cases he has not learned, and he therefore cannot tell if they illustrate in so clear a manner the relationship between rheumatism and chorea by showing that the most certain remedies for the former disease with which we are acquainted—the several compounds of salicyl—may exert a like curative action upon chorea. It would be important to still further test this point by treating a number of cases of chorea by salicyl compounds, and especially cases where the chorea does not present so close a relationship to the rheumatic affection as to suggest the possibility of its being a mere symptom of rheumatism. This view is, indeed, one that has been already adopted. Its existence led Dr. Frazer to dwell upon the importance of avoiding any all-pervading opinion in regard to this disease. Nothing will appear more obvious, when the known facts in regard to chorea are considered, than that it is far from being the product of any single pathological condition. There is now much evidence to show that, at times, it is accompanied by a lesion of the corpus striatum, at others of the medulla oblongata, at others of the medulla spinalis, at others of some part of the peripheral nervous system, at others of the heart, and at others by no lesion that can be discovered in any of these situations.

Dr. Frazer can scarcely hazard an opinion as to its production in the present case. The embolic theory is here entirely inapplicable, because of the rapidity

with which the disease disappeared on two separate occasions. The mere existence of cardiac disease, of rheumatic origin, seems equally insufficient to afford an explanation. It existed before the chorea, it has persisted after its disappearance; and, further, the chorea was rapidly cured by salicylates, whereas salicylates do not directly affect the occurrence or the course of cardiac disease in acute rheumatism. A reflex influence, originating from the inflamed joints, cannot account for the chorea, as it often appears in rheumatic patients, while no inflammation of joints is present; and, in our case, the joints were on several occasions acutely inflamed, without a reappearance or an exacerbation of the chorea. Such a case would almost indicate that chorea may be a mere manifestation of acute rheumatism, in the same sense as the joint or heart affections, a mere complication of that disease, produced, it may be, a rheumatic inflammation of some portions of the central nervous system, whether true nerve-substance or surrounding media.—*British Medical Journal*, December 9, 1882.

TREATMENT OF DIPHTHERITIC SORE THROAT.—DR. W. ALLAN JAMIESON has used M. Barff's boro-glyceride in conjunction with salicylic acid, in the treatment of this disease, and the results of this combined treatment have been highly satisfactory. The saturated solution of boro-glyceride in glycerine causes no pain when painted on the inflamed, ulcerated, or sloughy mucous membrane, but its use is immediately followed by relief to the symptoms. The disease, however, causes blood-poisoning, evidenced by the fever and the albuminuria, and against this the salicylate of sodium acts energetically, as has been seen in the recorded cases, which are but examples of what occurred in many others. With this treatment there have been no recurrences, no formation of abscesses; recovery has in all been rapid and satisfactory. In conclusion, he recommends a trial of the boro-glyceride in glycerine in ulcers of the mucous surfaces, as of the cervix uteri. The treatment has another advantage over any form of gargle, that by painting the inflamed surface we keep it at rest, instead of, as in the act of gargling, causing painful and injurious movement by the unavoidable contraction of the muscles of the palate and pharynx. In the case of children, even, little difficulty was experienced when they found not pain, but comfort, followed its use.—*Edinburgh Medical Journal*, December, 1882.

A NEW MOXA.—Under the name of "*crayon-feu*," DR. MOSES describes a preparation made as follows: Charcoal powder, 30 grammes; nitrate of potash, 4 grammes; pulverized iron, 5 grammes; benzoin, 1 gramme. The whole to be made up, with some adhesive substance, into forty crayons. He so obtains a hard preparation, which is easily inflamed by a match, and which he proposes for the cauterization of poisoned wounds, and when the actual cautery is required.—*Gaz. Hebdomadaire*, Dec. 1, 1882.

MYOSITIS OSSIFICANS.—At a recent meeting of the Vienna Medical Society, Prof. Podrazki exhibited a soldier affected with the rare condition which has been termed myositis ossificans. Four weeks previously the man had applied for treatment, on account of an intense inflammation of the muscles on the front of the right upper arm, apparently set up by severe gymnastic exercise. The muscles were large, hard, and uneven, and the elbow-joint was fixed in flexion. The hardness was removed, and some increased mobility was obtained, by massage and the application of cold. At the end of two weeks a hard, round, movable tumor developed in the flexor of the elbow, which was evidently due to an ossification of the brachialis anticus. At first it was movable, the upper part appeared to be cartilaginous, and it was evidently not connected with the periosteum. Podrazki has seen, in the course of nineteen years, two cases in the practice of Pitha quite similar to this in their characters. In those two cases neither iodide of potassium, nor any other treatment adopted, had any influence. In a discussion which followed, Prof. Weinlechner stated that he had twice seen similar small spots of ossification in the muscles on the front of the leg, due, in each case, to a traumatic cause. Kundrat expressed the opinion that some supposed exostoses on the thigh proceed from muscles. Their form and seat correspond to certain muscles. Their greater frequency in men, and especially in muscular individuals, suggests that their origin is traumatic. They constantly become adherent to bone in the course of their growth, and hence are commonly thought to be primary exostoses.—*Lancet*, December 16, 1882.

MALIGNANT ŒDEMA.—BRIEGER and EHRLICH, working in Frerichs' clinic, have recorded (*Berliner klin. Wochen.*, No. 44) two cases of an affection associated with typhoid fever in which they recognize a disease that in animals has been called "malignant œdema." This malady is an infectious one, and dependent on, or at all events associated with, a bacterium which has sufficiently well defined characters. The exciting cause of the malignant œdema in the authors' cases was a hypodermic injection of a musk solution administered as a stimulant to overcome the state of profound collapse into which both patients had fallen. Much swelling of the subcutaneous tissue, with emphysematous crackling and discoloration of skin at the site of the former injection (in the thigh in both examples), coming on in forty-eight hours, were the features descriptive of the malignant œdema. The authors remember to have met with another example of the affection in a case of diphtheria, but here there was no obvious exciting cause, and the emphysematous and œdematous conditions developed about the front of the chest. Inoculations of some of the fluid from the diseased thigh of the typhoid patients, performed on rabbits and guinea-pigs, brought about the usual characters of malignant œdema at the focus of vaccination, and the animals died in a few days. The existence of the septic vibrios was proved by the microscope (after the usual method of preparation), both in the fluids of the patient and in those of the animals experimented upon. Brieger and Ehrlich regarded their patients as suffering from a *mixed infection*, the virus of enteric fever and that of malignant œdema being both present at the same time. There are many facts in medicine which might be looked upon as demonstrating the predisposition which one complaint establishes for another—noma following measles and other acute specific diseases, tuberculosis after measles and whooping-cough, joint-suppurations after typhus, septicæmia after scarlatina, and many other examples. In the language of bacterial pathology, the human garden, by the action of one bacillus, is prepared and fitted for the growth and development of another micro-organism, which in the normal state of health would not have found so suitable a nidus.—*Medical Times and Gazette*, December 16, 1882.

TREATMENT OF FETID BRONCHITIS.—DR. E. LANCEREAUX recommends the hyposulphite of sodium in the treatment of fetid bronchitis; he combines it with the syrup of eucalyptus, 4 grammes of the hyposulphite to 30 of the latter. He has seen the greatest improvement in five cases treated on this plan.—*Bull. Gén. de Thér.*, November 30, 1882.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JANUARY 13, 1883.

THE EXISTING STATE OF OUR KNOWLEDGE CONCERNING THE BACILLUS MALARIÆ.

HOWEVER erroneous and ill founded were the conclusions of Dr. Salisbury, in the matter of the micro-organism he announced as the cause of malaria, his observations must be acknowledged to have become a part of the history of a subject which promises to be of vastly greater interest and importance than was for a long time anticipated. The names of other observers since Salisbury, but before the announcement in 1879 of the discovery by Klebs and Tommasi-Crudeli of a bacillus which is the cause of malarial disease, have been more or less associated with a micro-organism of similar properties, but no decided impression was made until the last-named published their results.

These observers found in the earth of malarial districts, in Italy, numerous shining oval and mobile spores, .95 of a micro-millimetre in the longer diameter. They were able to cultivate these spores in the animal body as well as in culture experiments, and the animals infected by them exhibited not only the clinical course of malarial disease as seen in man, but also the post-mortem appearances; while the bacillus was also found in the blood of such animals, taken after death. The spores develop in the animal body, as well as in culture experiments, into long threads, which are at first homogeneous, but later divide, while new spores develop in the interior of the segments. The position of the spores which are found either at the poles, or in the middle of the segment, serves as a mark of distinction between this and other pathological bacilli.

Following Klebs and Tommasi-Crudeli, Marchiafava and Cuboni, in Italy (*Archiv für Experimentelle Pathologie*, vol. xiii.), studied the blood of men ill with malaria. In this they found spores and bacilli which they declared to be identical with those described by the former. The spores included in the white blood-corpuscles were sometimes so numerous as to seem to fill them completely. Similar studies on malarial patients by Lanzi, and again by Peroncito, led to the same conclusions.

Succeeding these, Marchand published in Virchow's *Archiv*, vol. lxxxviii., p. 104, April, 1882, some observations really made in 1876, whence he concluded that there exists in the blood, in the cold stage of intermittent fever, mobile and flexible rods presenting slight swellings at their ends, and sometimes also at the middle. These end swellings he thought also might be of the nature of spores.

More recent still are the elaborate experiments of Prof. Ceri, of Camereno, Italy, published in the *Archiv für Experimentelle Pathologie*, vols. xv. and xvi., 1882. These consisted of culture experiments with organisms found in malarial and other soils, of experiments on animals, and culture experiments with quinine. They resulted in proving that the spores could be cultivated—Ceri applying the term *natural germs* to those found in the atmosphere and soil, and *artificial germs* to those which result from their culture; that animals could be infected by their injection into the blood, though to a less degree by the cultivated than by the natural germs, the former growing weaker in successive generations; and that the infecting properties could be retarded by the application of heat to culture fluids, and the introduction of quinine into them, certain degrees of the former, and strengths (1:800) of the latter making the culture of the spores impossible and arresting the putrid fermentation induced by them. The practical application of these facts is self-evident.

Finally the opportunity has recently been presented to Dr. Franz Ziehl to test these results clinically (*Deutsche Medizinische Wochenschrift*, Nov. 25, 1882) in three typical cases of malaria, in all of which the spleen was enlarged. In all three the bacilli above described were found in the blood taken from any part of the body by the prick of a needle, and examined in the fresh state, or dried in a thin layer upon a cover glass, by simply passing the latter over a flame. These have been preserved by Dr. Ziehl for three months without undergoing any change.

The bacilli thus observed were of different lengths, but usually were from one-fourth to the entire diameter of a red corpuscle. The majority of those measured were about 4 micro-millimetres long and .7 broad. Their ends were swollen and round-h.

The ratio of the diameter of the former to the latter varied, being sometimes as 1 to 2, sometimes more and sometimes less. They presented active flexions and movements among the red corpuscles, their motion being so slow that they often remained for half an hour in the field of view afforded by a Zeiss's objective F, and ocular I (about 410 diameters). With the same amplification there was present for the most part but a single bacillus in one field, and never more than three. In two of these cases *the use of quinine was followed by prompt relief and the disappearance of the bacilli from the blood in seven and nine days* respectively. The third case improved under the use of Fowler's solution but, unfortunately, no further examination of the blood was made.

Subsequently, Dr. Ziehl examined the blood of twenty-five persons, healthy or ill of other conditions than malaria. In *only one of these twenty-five* did he find bacilli, and these in considerable numbers. The man was a diabetic, in whom the disease clearly succeeded upon exposure. There was no history of malaria, but Dr. Ziehl, remembering that diabetes mellitus has been occasionally traced to malaria, put his patient upon quinine. The daily excretion of sugar, which had been reduced by opium and diet to one-half the quantity noted on admission, was not further reduced, but the *bacilli disappeared from the blood in eleven days* after the treatment was instituted. It would seem, therefore, that quinine acts as a parasiticide, in some way destroying the bacillus, or, at least, interfering with its development.

Should these observations be confirmed, and it must be admitted that the whole chain of evidence is much more conclusive than that adduced in favor of a *bacillus tuberculosis*, the whole mystery of the efficacy of quinine in the treatment of malaria would be solved. It is evident, also, that the question is one of much easier solution than that of the bacillus tuberculosis, and we predict a speedy settlement of it.

With a view of completing the presentation of the matter, we must mention a microbe claimed to have been discovered in the blood of persons suffering from malarial fever by Richard (*Comptes Rendus*, vol. xciv. p. 49), a French investigator, and named by Laveran *oscillaria malariæ*. This infests the red-blood disk, and its development is said to be analogous to that of a parasite in the lentil. We condense from our contemporary, the *Philadelphia Medical Times*, the annexed description of the microbe. In the blood of malarial subjects will be found some corpuscles presenting on their periphery a minute light and perfectly round spot, but which are otherwise exactly like the normal corpuscles. In a further stage of development the spot is larger and surrounded by a wreath of fine black nodules; around them hæmoglobin—recognized by its yellowish-green color—is deposited in the form of a ring, which diminishes as the microbe grows, until nothing is left of the cell except a marginal zone, whence the hæmoglobin is completely absent. Thus the microbe completely occupies the corpuscle, being still surrounded by the ring of black nodules. Finally, the fully developed oscillaria, which possesses several scarcely visible prolongations, perforates the membrane and escapes into the liquor sanguinis. Occasionally the prolongations, or fibres, which have a power of motion, alone perforate the membrane, and the microbe itself remains within the cell wall. Sometimes, also, the fully-grown microzyme is seen to move, and its fibres oscillate rhythmically, as "thin twigs would when held by their thicker ends and rapidly shaken." This movement continues about an hour, when it ceases, and only the dead body of the parasite is left. The dead parasites lose their shape, the ring of pigment is dissolved, and the whole appears as a gray mass, including a few black nodules, which are subsequently liberated and rapidly absorbed by the leucocytes.

Such is the somewhat fanciful description by Richard of the *oscillaria malariæ* which, he says, he was able to demonstrate in the blood of all persons suffering from malarial infection who came under his charge, while the severity of the disease was proportionate to the number of microzymes found in the blood. Kelsch and "a few other observers" are referred to as having noted these same phenomena. We have no critical comment to make upon these organisms other than that the changes described are strikingly similar to certain ones undergone by the red-blood corpuscles in the process of crenation and drying.

THE MEANING OF NYCTALOPIA AND HEMERALOPIA.

MEDICAL terminology, and particularly that of ophthalmic surgery, is often accused of being formidable, and it is not too much for those who undergo the labor of mastering it to expect that they shall be in possession of terms that are at least definite, if not etymologically correct.

Unnecessary changes are of course to be avoided, and if the name given to a disease or symptom can claim the universal consensus of medical writers, if it involves no absurdity and is free from ambiguity, the wisdom of tampering with it may be doubtful, even if it cannot be defended on either scientific or literary grounds. But if its etymology is more than questionable, its application absurd, and its use confusing, certainly the sooner it is consigned to the limbo of obsolete words the better. Nyctalopia and hemeralopia seem to be much in this position.

If we wish to record the fact that a patient's right leg is paralyzed, we do not do so by stating that his left is vigorous, and though we may indicate that the right half of his field of vision is gone by stating that the left half remains (*i. e.*, that he has left hemiopia, or half vision); the term hemiopia is usually translated as "half blindness," and of late we have the choice of the more rational expression hemianopia or hemianopsia, which is coming into general use. Not so with the writer who wishes to state, in one rather learned looking word, that his patient cannot see at night, or that he cannot see so well in daylight as at dusk. He is not allowed the benefit of a translation "by contraries," or the choice of another word, but must, perforce, commit a verbal absurdity and write down "hemeralopia" or "nyctalopia."

Among modern authors the use of the former term to express night-blindness and of the latter to express day-blindness is almost universal. However inconvenient and confusing these terms may have been, we have consoled ourselves with the belief that their etymology was settled, and their use sanctioned by an antiquity extending back into the mythical ages of medicine. Elaborate articles, however, by Drs. Greenhill and Tweedy, in the last two numbers of *The Royal London Ophthalmic Hospital Reports*, show that the etymology of these words admits of an amount of learned philological discussion sufficient to bring doubt to the most conservative mind, and that the use of them in their present sense is a comparatively modern and probably accidental innovation.

These authors say that Oribasius, Palladius, Aëtius, Alexander Trallianus, Paulus Æginata, Joannes Actuarius, and a host of others use nyctalopia in the sense of night-blindness. Galen, who distinctly explains nyctalopia to mean night-blindness in one of his works, has been accused of taking the opposite side in two others, but the latter are apocryphal. In fact, up to the middle of the seventeenth century, Hippocrates only can be cited as using nyctalopia in the sense of night-sight. About this time, the Hippocratic works were more generally consulted, and the passage—"Those who see at night, whom we call nyctalopes," etc., determined the meaning of nyctalopia, while hemeralopia came into use to indicate the opposite kind of sight. It is shown, however, that the description of the etiology, history, and treatment of the disease, which follows this passage, corresponds to night-blindness rather than to day-blindness; and a revised edition of Hippocrates is produced in which the word οὐχ is restored, making the passage read: "Those who do *not* see at night," etc., and undermining the faith that has inspired many generations of medical authors.

Drs. Greenhill and Tweedy have done a great service to medical literature by determining, at the expense of much labor and learning, the true meaning of these words; but we fear that it will hardly be possible while they remain in use "to put an end to the confusion which has existed for considerably more than a thousand years." It would probably be easier to change the terms than to reverse their accepted meaning. As hemianopsia and hemiachromatopsia have definite and unmistakable meanings, might not some such words as nyctanopsia and hemeralanopsia be made equally useful?

AN IMPORTANT DECISION AS TO QUARANTINE FEES.

A DESPATCH dated New Orleans, January 2, states that a perpetual injunction restraining the Board of Health of that city from collecting quarantine fees, has been granted by the District Court on the application of the Morgan Railroad and Steamship Company. Judge Monroe, in delivering the opinion of the Court, concluded as follows: "It is remarkable, in view of the fact that the convention which adopted the Constitution of the United States distinctly determined, after the most elaborate and earnest discussion, that the States should not be allowed without the consent of Congress to levy duties on tonnage for any purpose whatever, that it should still be considered a matter of discussion as to whether such duties may not be imposed for the support of a police or quarantine established by a State for the protection of the health of its citizens. There is no reason for requiring that the quarantine service should be supported by those who are under no legal obligations to do so."

As the quarantine fees are the chief source of revenue of the New Orleans Board of Health, which receives no appropriations from the city or the State, this decision to a large extent deprives it of funds. The opposition of the New Orleans Board of Health to the National Board, and especially to the Ship Island Quarantine, has been no doubt influenced to a certain extent by the fear that its revenue from quarantine fees might be diminished if vessels were allowed to perform quarantine elsewhere than at its own station, but it may now be able to take a more impartial view of the matter. This decision, if sustained by the superior courts, before which it will no doubt be brought in some way, affects all ports of the United States where quarantine fees are charged, and it would seem as if under it one or two things must follow: *i. e.*, either the States or cities must appropriate the necessary funds for maintaining these quarantine inspections, or the general Government will be asked to assume the expense, and take charge of the matter.

Not having the full text of the decision before us,

it does not seem worth while to comment further on the matter at present, but it is possible that this is the first step towards a really national system of quarantine.

THE INFLUENCE OF ARSENIC ON THE FORMATION OF SUGAR.

THIS subject has been studied by M. LE DR. LONGEVIALLE, both by physiological experimentation and by clinical observation. He has ascertained that the saccharine condition of the urine produced by puncture of the floor of the fourth ventricle, is very greatly diminished by the simultaneous administration of arsenic. He has further observed that in cases of diabetes the quantity of sugar is equally diminished by the administration of Fowler's solution. This medicine he administers in doses which, to our notions, are rather extreme, giving from ten to thirty drops daily, and increasing the quantity up to the tolerance of the stomach. The result is striking. Not only is the quantity of sugar greatly reduced, but the simultaneous waste of the nitrogeneous materials in the form of urea is also much diminished. With the diminution in the quantity of urea and of sugar, a notable decline in the quantity of the urine passed also takes place.

We are able to confirm these observations as regards the power of arsenic to check the formation of sugar, and the excessive production of urea, in cases of glycosuria. Although Longevialle has reduced to scientific expression the utility of arsenic, it must be admitted that it has long been known that arsenic is a useful remedy in diabetes. The clinical fact now receives scientific confirmation, but the fact has, nevertheless, long existed.

THE Pseudo-bacillus Tuberculosis of Schmidt, we feel, should be the term applied to the object of the studies of Dr. Schmidt, of New Orleans. That this object is a fat crystal derived from the fat so abundantly present in the sputum of tuberculosis, as well as in tubercle itself, there is every reason to believe. But that this is the object which has been called the bacillus of tuberculosis by Koch and others is not at all likely. No further proof of this ought to be required than the demonstration by Dr. J. Gibbons Hunt, at the College of Physicians of Philadelphia, last Monday night. That the pseudo-bacillus is a crystal, is proved by the fact that it *polarizes* under the microscope, while the true bacillus does not polarize. These different properties were shown side by side. Otherwise the two objects are similar, but Dr. Schmidt has mistaken the crystal for the real thing, which it closely resembles.

IT is important to publish widely the fact that in Illinois one Lambrecht has recently been detected in an attempt to personate Dr. Heinrich Andreas Lüders, a graduate from the University of Göttingen in May, 1866, who died in November, 1878. Lambrecht, who is a barber by trade, became in some way possessed of the diploma of the dead man, and attempted to register under it; and although, by reason of suspicious circumstances connected with the application, the required certificate was held back for some time by the Illinois State Board of Health, it was finally obtained in two years from the date of application, and he began to practice in Collinsville, Ill. The fraud was discovered by correspondence with the dean of the medical faculty of Göttingen, but not until the man had sacrificed a mother and infant in the attempted *rôle* of obstetrician. The scoundrel escaped, however, before he could be arrested, and may attempt the same game in some other State, where requirements of registration are less rigid, or do not exist at all.

Attempts at personating others through diplomas acquired by theft or otherwise are not infrequent, and suggest a rigid examination as to the identity of the individual with the name on the diploma. In this instance, the unscrupulousness of the man in forging letters of recommendation enabled him to deceive the Secretary of the Board. Had an affidavit before a justice of the peace, properly executed, been required in addition to the letters of recommendation, another obstacle to the success of the fraud would have been interposed.

THE new year has brought with it the usual number of alterations in our exchanges.

The New York Medical Journal has been converted from a monthly to a weekly, of 28 octavo double-columned pages, with the usual diversity of matter. The first number contains for its leading article Dr. W. B. Carpenter's initial lecture on Human Automatism, a full abstract of which was laid before our readers in our issue for December 2d. The journal remains under the editorial control of Dr. F. P. Foster.

The Sanitarian likewise becomes a weekly publication, and the first number consists of sixteen handsome double-columned quarto pages. It remains under the able editorial control of Dr. A. N. Bell, who is assisted by Dr. T. P. Corbally. The opening number contains papers by Drs. Cabell, Bowditch, Peters, and others.

The Medical Record, with the new year, appears in new type, a greatly improved dress, and a lengthened page, and it announces its intention of availing itself of all the resources of modern medical journalism.

The Detroit Clinic and *The Michigan Medical News* pass under the control of Mr. George S. Davis, and will be combined and published hereafter under the title of *The Medical Age*.

THE cost to the Government of the star route trials has just been made public, and we learn that Mr. George Bliss has been paid up to December 1st $40,660.34, and the total sum paid to special counsel at that date was about $70,000. Judge Porter and Mr. Davidge each received for his services in the Guiteau trial $10,000, and Mr. Edwards Pierrepont was paid $3,099.25 in the past year for his services in the discontinued Tilden income-tax suit. These sums have been paid without eliciting a word of comment from the same Congress which, with considerable appearance of virtue as well as economy, denounced the extravagance of the sum it was proposed to pay the four surgeons who were in attendance upon President Garfield, and then created the Board of Audit which subsequently awarded them the total sum of $20,500. We commend these figures to the thoughtful consideration of the profession and the public.

SOCIETY PROCEEDINGS.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting, January 3, 1883.

THE PRESIDENT, W. S. W. RUSCHENBERGER, M.D., IN THE CHAIR.

DR. JOHN B. ROBERTS read a paper on

HEART-PUNCTURE AND HEART-SUTURE AS THERAPEUTIC PROCEDURES.

It is more than probable that in a few years puncture of the heart-wall (cardicentesis), with direct abstraction of blood by aspiration, will be recognized as the best treatment in cases of greatly dilated or much distended right heart, with intense pulmonary engorgement; and that incision of the pericardium, with suture of the heart muscle, will be accepted as proper in cardiac wounds. Hence these latest novelties in cardiac surgery deserve the attention of the Fellows of the College.

That punctures of the heart are comparatively harmless has been well known to many for some years. In 1872, Roger, while performing pericardicentesis on a child with pericardial effusion, thrust the needle into the right ventricle and withdrew about 6¼ Troy ounces (200 grms.) of pure venous blood. The boy, who was aged five years, became pale, sweated, and had an imperceptible pulse. The withdrawal of the pericardial fluid, accomplished prior to the heart injury, was beneficial; and the cardiac puncture did no permanent mischief, for the patient recovered. Death occurred five months later from long existing dilatation and valvular disease of the heart (*Bull. de l'Académie de Médecine*, 1875, p 1276).

In Hulke's case (*Trans. Clinical Society of London*, viii. p. 169), a woman with pleuro-pneumonia was supposed to have large pericardial effusion, and a trocar was introduced through the fourth left intercostal space. Nothing escaped except a drachm of venous blood, after which the patient seemed relieved of dyspnœa. She died four weeks later from a complication of diseases, and the autopsy revealed cardiac dilatation and valvular changes.

I have said elsewhere (*Paracentesis of the Pericardium*, 8vo., Philadelphia, 1880), in commenting upon this case: "The abstraction of blood seemed to relieve the distended heart much better than phlebotomy would have done, as was evinced by the diminution of threatening symptoms and the decrease of the area of dulness."

Cloquet, Bouchut, Legros, and Onimus have also observed the apparent innocuousness of wounds of the heart made by capillary trocars. Steiner found, ten years or more ago, that electro-puncture needles could be quite safely introduced into either ventricle, provided they were at once withdrawn (*Med. Times and Gazette*, May, 1873, p. 492, from *Langenbeck's Archiv für klin. Chirurgie*).

It has been considered less safe to puncture the auricles; but the interesting paper of Dr. Benj. F. Westbrook, just published in the *Medical Record* for December 23, 1882, seems to show that our fears are as unfounded as were those of our predecessors in regard to ventricular puncture. It is, in truth, to call attention to his case of harmless *intentional* cardicentesis and to his researches in the surgical anatomy of the operation, that I have been led to refer to the corroborative evidence of the cases mentioned above.

I have with much satisfaction, as have many others, done venesection at the bend of the arm for the temporary relief of the distressing symptoms of dilated heart, and for the dyspnœa due to the pulmonary engorgement of acute pneumonia. If, however, a few *drachms* of blood drawn directly from the heart give the relief that could only be afforded by taking a similar number of *ounces* from the veins of the arm, it seems proper to adopt the former measure. The subsequent circulatory depression from anæmia would undoubtedly be less than after the latter operation.

It is manifestly necessary, however, to determine that cardicentesis is innocuous before it can take the place of venesection. The above-mentioned cases and Dr. Westbrook's experience tend to show that such is the fact.

Dr. Westbrook believes that the proper place to perform the operation is in the third costal interspace close to the *right* edge of the sternum. This situation enables the operator to tap the right auricle without injuring the right internal mammary vessels, and with little danger of striking the tricuspid valve. My own preference would be to perforate the ventricle of the right heart by introducing the needle through the fourth interspace, about one and a half or two inches to the *left* of the median line of the sternum. Dr. Westbrook's opinion, however, is entitled to more deference than mine, because he has studied the subject with special reference to cardicentesis, while my special investigations have been limited to the consideration of pericardicentesis.

Further experimentation in heart-puncture for the relief of cardiac distention and pulmonary engorgement is requisite, but it is probable that it will soon become a well-recognized surgical procedure in selected cases. Pericardicentesis has already taken that position, and there is no reason to believe that cardiac surgery will stop its march with the demonstration that the pericardium can be treated as the pleura.

In October, 1881, I read a paper before the Anatomical and Surgical Society of Brooklyn (*The Surgery of the Pericardium; Annals of Anatomy and Surgery*, December, 1881), in which I advised resection of the costal cartilage and incision of the pericardium for removal of foreign bodies in the pericardial sac; and at the same time said: "The time may possibly come when wounds of the heart itself will be treated by pericardial incision, to allow extraction of clots, and perhaps to suture the cardiac muscle."

It seems as if this time had now almost arrived, for Dr. Block has not only expressed a belief that death

can be averted in many cases of heart-wounds by simple incision of the pericardium to allow escape or extraction of the clots which cause pressure and death, but has also undertaken to demonstrate by vivisectal experiments that suture of the heart is a simple operation and requires but three or four minutes (*Amer. Journal of the Med. Sciences*, January, 1883, p. 276; from *Journal de Méd. de Paris*, Oct. 28, 1882; from *Gaz. Méd. de Strassbourg*, Oct. 18, 1882). He finds that opening of the right and left ventricles, and entire compression of the heart for the application of sutures, can be supported by rabbits for several minutes. During suturing he seizes the apex of the heart and draws the organ forward until the traction prevents the escape of blood from the wound. Sutures are then introduced, or the orifice closed by ligation. Even if cardiac pulsation and the respiration stop during this mechanical interference with the heart's movement, death, he asserts, does not necessarily ensue.

These experiments are even more important than the researches spoken of in regard to heart-puncture. I regret that as yet I have not been able to consult Dr. Block's original memoir, but I hope at a future time to do so, and perhaps to be able to report some investigations of my own which I desire to make in the same direction.

The following Fellows were then elected

OFFICERS FOR THE ENSUING YEAR.

President.—Alfred Stillé, M.D.
Vice-President.—J. M. Da Costa, M.D.
Secretary.—R. A. Cleemann, M.D.
Treasurer.—Chas. Stewart Wurts, M.D.
Curator.—Thomas Hewson Bache, M.D.
Honorary Librarian.—James H. Hutchinson, M.D.
Recorder.—J. Ewing Mears, M.D.
Censors.—Drs. Lewis Rodman, Edward Hartshorne, William Goodell, and Samuel Lewis.
Councillors (to serve three years).—Drs. S. Weir Mitchell and W. S. Forbes.

The following resolution complimentary to

THE RETIRING PRESIDENT

was unanimously adopted.

"*Resolved*, Inasmuch as the term of the retiring President of the College, W. S. W. RUSCHENBERGER, M.D., has just been completed under the limit prescribed by the by laws, the Fellows of the College hereby respectfully and cordially congratulate him upon the very successful termination of his official services, and upon the long-continued, constant, and faithful administration which has distinguished those services not only in the Presidential Chair, but in his unremitting, wise, and watchful attention to the interests of the College.

"They take especial pleasure in expressing the grateful appreciation of the College, and in recording the fact that throughout his nearly four years of service as Vice-President, and his subsequent four years of service as President, Dr. Ruschenberger, while holding always the pleasantest relations with his Fellows of the College, has never been obliged by ill health or other cause to absent himself from his post, either at the meetings of the College or of the Council."

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, January 4, 1883.

THE PRESIDENT, FORDYCE BARKER, M.D., LL.D., IN THE CHAIR.

The result of the

ANNUAL ELECTION

of officers for 1883 was as follows:

President.—Fordyce Barker, M.D.
Vice-President.—H. P. Farnham, M.D.
Recording Secretary.—W. H. Katzenbach, M.D.
Corresponding Secretary.—J. G. Adams, M.D.
Treasurer.—William F. Cushman, M.D.
Trustee.—G. M. Smith, M.D.
Treasurer of Board of Trustees.—Charles Wright, M.D.
Mem. of Com. on Admission.—E. L. Partridge, M.D.
Mem. of Com. on Ethics.—H. E. Crampton.
Mem. of Com. on Education.—J. C. Dalton, M.D,
Mem. of Com. on Library.—F. R. Sturgis, M.D.

The scientific work of the evening consisted in the reading of a paper by DR. FRANCKE H. BOSWORTH, on

TUMORS IN THE NASAL PASSAGES.

By nasal passages, he said, was meant the whole of the physiological air tract from the nostrils to the lower part of the soft palate.

The most frequent form of growth is the adenoid in the vault of the pharynx. It consists simply in a hypertrophy of the glands normally found in that region. It is a rather common belief that adenoid tumor in the vault of the pharynx is a rare and obscure disease, whereas Dr. Bosworth had found it a most common affection. The point from which he wrote was that this was one of the conditions which gave rise to so-called nasal catarrah. Nasal catarrh, however, was to him a meaningless term. There were a number of different conditions which gave rise to discharge from the nose. In a very large number of instances the discharge is the result of a definite morbid condition, the removal of which results in radical cure of the disease.

Among the common causes or sources of nasal catarrh were mentioned in passing rhinitis hypertrophica, deviated septum, adenoid growths in the vault of the pharynx, nasal polypus, presence of foreign bodies, syphilitic ulceration or necrosis, and strumous ulceration. These were diseases which generally presented to the physician for treatment as nasal catarrh.

During the last twelve months seventy-five cases of these growths (adenoid) had come under Dr. Bosworth's observation. Five were in patients under the age of ten, forty-three between ten and twenty, twenty-three between twenty and thirty, two between thirty and forty, one between forty and fifty, and one in a patient over fifty. Of these, forty nine were females and twenty-six males. These cases all presented for treatment of nasal catarrh. We thus find the largest proportion of these cases occurring in patients below the age of twenty. The deduction from this is that the disease is essentially one of childhood, and that with the development which occurs at puberty, these growths gradually disappear.

The existence of these growths has long been recognized, but was first accurately described by Luschka, from whom the disease received the name of Luschka's tonsil. Woakes, of London, describes adenoids as consisting of a papillomatous structure; Meyer, of Copenhagen, and Loewenberg, of Paris, described them as being glandular. The analogy between these and the faucial tonsil seems complete, both in an anatomical, physiological, pathological, and clinical point of view.

Symptoms.—The most prominent symptom to which these growths give rise is that of an abnormal secretion, which is composed of mucus or muco-pus. The morbid process giving rise to the hypertrophy does not destroy the secreting function of the glands, but rather increases it. The secretion makes its way out through the nostrils or down the throat.

Another symptom is a change in the voice. Their presence gives rise to what Meyer calls the dead voice, the nasal resonance being destroyed as in an ordinary cold, so that *M* and *N* become *Eb* and *Ed*. The fact of even a small adenoid growth in the vault of the

pharynx upon a singing voice offers many points of interest. The conversational voice does not tax the full capacity of the larynx. A person with a considerable degree of laryngeal disorder will experience no special difficulty in an ordinary conversational use of the voice. Singing, however, taxes the very highest capacity of the larynx, and demands that not only the larynx, but the pharynx and the nasal passages shall be in a state of perfect health. In the lower or chest register a healthy larynx of course is essential, and notes in this register are taken with ease and clearness even when disease may exist in the nasal cavity. The vocal cords regulate the pitch tension of the voice, but the quality of the voice is governed or depends upon the nasal cavity, largely; so that while it is a matter of common observation among singers that it is the head register that first gives out, this illustrates what Dr. Bosworth has always urged, that the so-called catarrhal laryngitis is, in the majority of instances, a secondary affection and depending on the catarrhal disease of the nasal cavity. The laryngitis therefore becomes merely a symptom of the nasal disease. The method by which the singing voice becomes affected from the presence of adenoid growths in the vault of the pharynx is quite simple. The prominent function of the pharynx is that of a sounding-board, and in order that this sounding-board function shall be exercised, the pharynx must necessarily present a smooth, rounded, dome-like cavity against which the vocal waves may strike and be reflected. If, then, this region is the seat of an adenoid growth, the voice becomes muffled, and loses something of its proper resonance and quality. The singer becomes conscious of this loss of tone and unconsciously, perhaps, makes a renewed effort to overcome this obstacle. In doing so he ruptures some of the capillaries in the larynx or muscular fibres, thus bringing on secondarily a laryngitis. A strained voice is the result.

Impairment of hearing is not an infrequent accompaniment of adenoid disease in the vault of the pharynx. It is a common belief that this symptom is due to an extension of catarrhal disease into the Eustachian tubes. Dr. Bosworth was disposed to regard this as a very infrequent occurrence. In making an examination by inspection of the orifices of the Eustachian tubes, it is exceedingly rare to find any evidence of catarrhal inflammation in them.

Dr. Bosworth also said that it was commonly believed that the ear symptoms were due to pressure upon the Eustachian orifices. Adenoid tumors are soft, pulpy masses, having very little resistance, and, as the Eustachian orifices are composed of hard, dense, cartilaginous, or horny tissue, they could not likely be affected by pressure of soft adenoids. The real explanation of impairment of hearing, urged by Dr. Bosworth, was that it was due to interference with the renewal of air in the middle ear. The constant and ceaseless impulse of vocal waves upon the tympanum necessarily acts to rarefy the air in the middle chamber. To counter-balance this, we have the movement of the faucial muscles. The presence of an adenoid growth very markedly interferes with the free play of the levator palati muscles, and, therefore, interferes with the renewal of air function. The growth, of course, does not oppose any obstacle to the levator palati muscle itself, but the elevation of the palate. Moreover, any cause which interferes with free nasal respiration, acts to produce a certain amount of rarefaction of air in the pharyngeal vault. It is thus that nasal stenosis, to which the presence of an adenoid growth gives rise, acts still further to rarefy the air in the middle chamber, thus causing impairment of hearing.

Recurring attacks of earache were present in a certain number of cases, and in two cases there were attacks of otitis medii. In one case, tinnitus aurium existed, with impairment of hearing, which was markedly relieved, though not cured, by the removal of the growth.

Nasal stenosis is a prominent symptom in the presence of an adenoid tumor. It is due to the mechanical interference with the to-and-fro flow of currents of air. It is a very noticeable fact in these cases that under the influence of damp weather these growths become swollen and turgid to such a degree that they are very markedly larger on inspection at one time than at another. The point examined will sometimes appear very small; at other times puffed up. In this feature, the disease presents some of the characteristics of nasal polypi.

The disease is purely a local one, the inflammatory affection involving these glands always manifesting itself in a hypertrophy, and never in an atrophy. The morbid process confines itself to these glands.

In four of Dr. Bosworth's cases, disease occurred in connection with atrophic rhinitis, but in by far the larger proportion of cases it occurred in connection with rhinitis hypertrophica. In about one-half of the cases it occurred independently of any other morbid process.

Diagnosis.—The diagnosis is made by means of a rhinoscopic examination. Loewenberg and Meyer direct that digital exploration should be made in all cases. This, Dr. Bosworth did not consider to be necessary. It was only accomplished with discomfort to the patient, and unnecessarily excites more or less terror and apprehension on the part of the child. A better and clearer conception of the size and position of the tumor can be obtained by means of the rhinoscope. To make an examination, sunlight should be used in all cases, as the ordinary gas jet is not sufficient to thoroughly illuminate the parts. That there is any difficulty in making a rhinoscopic examination of children is an entire mistake. The confidence of the child is easily gained, and with a little adeptness of manipulation and patience, a satisfactory inspection can be obtained. Dr. Bosworth recalled no single instance where he had not been able to make this examination in children.

Treatment.—The treatment consists in the removal of the growths. The question arises whether an operation is demanded, in view of the fact that they sometimes disappear with the development that occurs at puberty. Dr. Bosworth claimed that their presence always gave rise to symptoms sufficiently prominent to demand their removal without regard to this feature. Not only should the existing symptoms be relieved before removal, but the threatened dangers of disorder lower down as a result of their presence. The presence of this growth undoubtedly gave rise to a tendency to weak throats, and bronchial troubles as the result of the habitual mouth breathing which they induce.

Various devices have been used for extirpating these tumors. Meyer, of Copenhagen, uses a ring knife. This consists simply of a ring with the cutting edge on the inside, mounted on a straight rod. The instrument is passed through the nose, and manipulated by means of the finger passed in the mouth behind the palate, and the growth shaved off. He follows this operation by passing a long curved instrument, having a rasp on its convex surface, by means of which instrument passed into the mouth he rasps the base of the tumor. Finally, he cauterizes the surface. Meyer unquestionably does his work very thoroughly as his record shows. He has operated upon between three and four hundred cases.

The question arises, cannot this work be done by much simpler means? Woakes, of London, Cohen, of Philadelphia, and others recommend a pair of curved

forceps with a cutting bite, which is passed behind the palate, and the growth seized and torn away. This seems to be a rude and harsh procedure. Loewenberg, of Paris, Michel, and Voltalini use the galvano-cautery. There are two methods by which this device may be used: Either by the heated wire severing the mass, or by destroying it by the flat electrode. The first method is not feasible. As a directly destructive agent, Dr. Bosworth believes the galvano-cautery to be immensely over-estimated. It is an expensive and ponderous instrument, and always getting out of order; and, moreover, for the purposes of destruction it does not accomplish what has been claimed for it. If a cold electrode is placed upon the growth, and the current closed the loss of heat is so great that it is impossible to develop even a dull red heat. The destruction of tissue is therefore limited. If heat be developed in the electrode before entering, it is almost impossible to pass it without burning healthy tissue. MacKenzie recommends the use of the curette. This instrument Dr. Bosworth formerly used, but found it difficult to remove any but simple growths with it.

The instrument which the author of the paper made use of was an adaptation of Jarvis's snare. In his hands it had answered a most admirable purpose in the removal of these growths. The distal end of the tube is bent to a quadrant of a circle, with the radius of one and a quarter inches. The instrument is fitted with a loop of No. 5 piano wire, of a size which it is judged will embrace the growth. The loop is now bent forward to a right angle with the distal orifice of the instrument. The wire is then drawn out about one-eighth of an inch, and the whole of the loop is now bent backward toward the hand. The wire now has two kinks in it. The instrument with the loop in this position is readily passed behind the palate and to the vault of the pharynx with the extremity of the tube lying immediately behind the tumor. As the screen at the proximal end of the instrument is slowly turned, the loop is made to swing up and embrace the growth, which is slowly severed. The rigidity and firmness of the steel wire render this procedure an exceedingly simple matter. By this simple device even a broad sessile growth can readily be removed. The operation is attended with but little pain and trifling hemorrhage, and is not difficult to perform. The growth is either drawn out with the instrument or blown into a handkerchief through the nose. Dr. Bosworth has never had the slightest inconvenience from these growths dropping into the air passages. He has, however, occasionally lost a specimen by its being swallowed. No anæsthetic is required. The operation of course necessitates a certain amount of faucial control on the part of the patient, as the loop cannot be passed unless the palate is entirely relaxed. Occasionally, Dr. Bosworth has been compelled to operate through the nose in young children on account of an irritable throat. In these cases an anæsthetic has been given, and the operation performed with the ordinary straight Jarvis's snare. The method by which this has been done is as follows: The snare is fitted with steel wire as before, the loop being of proper size to embrace the growth. The loop is then bent downward, and to a right angle with the orifice of the tube. Having done this, it is drawn into the tube until sufficiently small to pass readily through the nares. It is then passed in a vertical position until it reaches the pharynx, where it is turned in such a manner that when the wire is pulled out through the tube, the kink which has been given it, will turn the loop downward. When in this position the end of the instrument is pressed firmly against the pharynx, and the loop drawn home by means of the screw at the proximal end of the tube. The same procedure is repeated in each nostril. Complete anæsthesia is not necessary, as the operation is completed in from one to two minutes, the child being immediately aroused and directed to blow its nose.

Nasal Polypus.—The next class of nasal tumors to which Dr. Bosworth called attention was nasal polypi. This disease has been recognized since the days of Hippocrates, and is treated of in all text-books to the present day. The morbid condition consists of the presence in one or both of the nasal cavities of one or more soft gelatinous bodies which block up the passages, and give rise to more or less profuse secretion or discharge.

Properly speaking, the term polypus means pedunculated tumor. As a clinical fact, the only pedunculated tumors met with in the nose are nasal polypi. In structure these tumors are pure myxomata. A proper classification would demand that these tumors be recognized as such. Fibromata never become pedunculated. They are always sessile growths. In current literature a fibroma of the nasal pharynx is usually spoken of as a naso-pharyngeal polypus. During the last year there were treated at Dr. Bosworth's clinic at Bellevue Hospital 1641 cases of throat and nose affections. Of these, there were 19 cases of nasal polypus. During the same time he saw and operated upon 16 cases in private practice. Of these 35 cases, 2 were under 20 years of age, namely, 11 and 15 years; between 20 and 30 years of age there were 9 cases; between 40 and 50, 12 cases; between 50 and 60, 6; between 60 and 70, 4 cases; 20 were males, 15 females. In a large number of cases the disease occurs in both nostrils. In those cases in which they are found only in one nostril the tumors are few in number and small in size. This fact would argue that the disease commences in one nostril and subsequently develops in the other. They spring from the under surface of the middle turbinated bone in a large proportion of the cases. Dr. Bosworth recalled but two cases in which they sprang from the septum. They are pear-shaped bodies attached by a narrow pedicle. Their shape is probably due to their soft consistency. Under the influence of gravity and the to-and-fro movements of inspired air they are drawn out and hang in the cavity. They rarely assume much size, simply from the fact that they have no room for development in the narrow nasal passages. Occasionally they develop near the posterior nares and drop into the pharynx, where they have more abundant room for growth, and therefore attain a larger size. Dr. Bosworth showed two polypi nearly of the size of hens' eggs, which were removed by operating through the nares. We were generally taught that this disease was the result of nasal catarrh. Dr. Bosworth thought that nasal polypus is a disease by itself, having no special connection with nasal catarrh or chronic rhinitis. In a majority of his cases, after the removal of the polypi, the nasal mucous membrane was found healthy. In a certain proportion of cases there was chronic hypertrophic rhinitis. In four cases there was atrophic rhinitis, which would seem to argue that there is no connection between these affections and hypertrophic catarrh. In two instances the writer had removed polypi from the borders of syphilitic ulcers in the nose. This would indicate no connection between syphilis and nasal polypi, the growths being simply the result of local morbid changes.

Ordinary symptoms were briefly referred to. They consist in a watery discharge, the hydroscopic character of the tumors, a nasal stenosis, etc. Sneezing was referred to as a prominent symptom of nasal polypus, and one whose importance is usually underestimated. The irritability of the nasal mucous membrane in chronic rhinitis is impaired, and sneezing is not a symptom of ordinary chronic nasal catarrh. In

the early stages of nasal polypus, repeated and violent attacks of sneezing are very common. This symptom is always suggestive of the disease, and when it exists without apparent cause, the nasal cavity should be explored.

In three cases asthma was present, and depended upon the existence of these growths. The asthma presented all the characteristics of ordinary spasmodic asthma, the physical signs, together with nocturnal exacerbations, being present. In two cases the asthma was entirely cured by the removal of the polypi without the administration of remedies. In one case in which it had existed for two years, the asthma was only relieved by the administration of iodide of potassium for three months after the polypi were removed. This reflex symptom of nasal polypus (asthma) was first noticed by Voltalini, in 1871. Since then additional testimony has been adduced by Daly, Frankenkel, Rumbold, Spencer, Todd, Porter, and Holden.

Treatment.—The earliest treatment recommended for the removal of these growths was that by Hippocrates. This consisted in passing a string through the nares, to the end of which a large piece of sponge was tied, which was then drawn back through the nasal passage, bringing out with it some of the growths. It is a strange fact that this procedure is still recommended in some books.

Injections with acetic acid, tincture of iodine, persulphate of iron, and corrosive sublimate have been recommended. The result of the use of these injections into the growth is its necrosis. The polyp sloughs away after from three to five days, during which time the patient suffers from offensive, watery, and fetid discharge from the head. It is impossible to inject more than one or two polypi at a time. Hence, for the eradication of all the growths, a long course of treatment is necessary, during which time the patient is practically suffering from an offensive form of ozæna. All works on general surgery recommend the use of forceps for the removal of these tumors. This method is perhaps the one most universally resorted to. We are directed to pass the forceps in and seize the pedicle of the polyp, and drag it out. Dr. Bosworth said that he had never seen a pedicle of the polypus until after it was removed. Hence this procedure is impossible by inspection. If it is meant to pass the forceps in and feel for the pedicle, the result is that a harsh instrument is passed into an exceedingly sensitive cavity, and made to grope about, until something is seized upon, whether it be healthy or diseased tissue, and is dragged forth. Healthy parts, in all cases, are bruised and mutilated. Violent hemorrhage is the result of the first introduction of the forceps, and all subsequent procedures are entirely in the dark. It is one of the most unsurgical proceedings that Dr. Bosworth knew of. Moreover, all the tumors cannot be removed by the forceps. We are, therefore, directed to remove a portion of the turbinated bone. The healthy mucous membrane upon the turbinated bone has a certain function to perform in the economy, and its removal is unjustifiable without sufficient cause.

The galvano-cautery recommended by Middledorphf is probably efficient. Dr. Bosworth's objection to this was that it was a bungling instrument. Moreover, the use of a heated wire in the nasal cavity is liable to do a great deal of injury to healthy tissue. The introduction, by Hilton, of the snare was the first thoroughly surgical method of removing these growths. The snare was mounted with the soft wire, which was passed around the growth, tightened, and the polyp evulsed. This procedure was liable to leave a portion of the polyp tissue in the nose.

Jarvis's snare écraseur furnishes us with an instrument which leaves nothing to be desired. The steel-wire loop with which it is provided being firm and resisting, can be carried in any direction in the nasal cavity, and easily manipulated so as to embrace the smallest growth. This difference should be noted between the action of the snare and the action of the écraseur. In the snare the growth is seized and evulsed, in the écraseur the growth is embraced and severed by a slow process of écrasement. With this instrument, when the operation is done deftly, a long shred of fibrous tissue is easily dragged out from the healthy mucous membrane. Dr. Bosworth was not a believer in roots, but if there was a root of a polypus this is the root, and another polypus does not develop at this spot. In the specimen shown, this fibrous shred was easily recognizable. The only objection to the ordinary snare is that in deeply seated growths the hand of the operator obscures inspection of the nasal cavity. To overcome this, Dr. Bosworth made a combination of Jarvis's écraseur and wire snare.

As to the recurrence of these growths Dr. Bosworth expressed the opinion, that if they were thoroughly relieved they would not occur. The operation, it should be stated, is done with but little pain and no hemorrhage, and can be continued from day to day until all the growths are removed. He had not found it necessary to apply a cautery to the base in order to prevent the recurrence of the growths. They were to be treated as you would weed a garden.

DR. LEFFERTS was called upon to open the discussion. In doing so, he said that there were many points in Dr. Bosworth's excellent paper that needed no discussion. On the other hand, there were some statements made by Dr. Bosworth which he thought it would be well to consider. First among these was that adenoid tumors of the naso-pharynx were generally believed by the profession to be rare. Dr. Lefferts declared that any one who had read the journals could not help having noticed this subject treated of almost *ad nauseam*. The speaker, however, had not found these adenoid vegetations so comparatively common as the statements of Dr. Bosworth and the numerous pathological specimens presented by him this evening would seem to indicate.

The fact that a large number of these growths were exceedingly small and could hardly be considered as an abnormality, should not be overlooked. The author of the paper had not laid sufficient stress upon this point. The question was asked, is it always necessary to remove these growths? Dr. Lefferts believed not. His reasons were that at a certain age, namely, that of puberty, these growths disappear by a gradual process of atrophy. Hence, he thought it was desirable not to operate in any of these cases unless the symptoms were of an aggravated character. He agreed that there were cases causing a certain amount of interference with a child's voice, and giving rise to other disagreeable symptoms which required attention. The majority of children that were brought to him having these growths, were brought on account of having nasal catarrh. There was usually found a condition of hyper-secretion. In these cases it was his practice not to operate, but to wait until the time had passed for the atrophy of these tissues to take place. Hence, he would not advocate their treatment by removal.

As to treatment, Dr. Bosworth had run over the various methods in use, and summed up by recommending the method of removal by means of Jarvis's snare, which instrument, the speaker said, had figured largely in the author's writings of late. This instrument answers the purposes of removal very well, but it has not met with general approval on the part of the profession. The speaker stated that it was not generally used by those engaged in this special practice. While in Europe, Dr. Leffert's attention had been called

to a new form of forceps which answered every purpose, and did not require for their use so much skill as Dr. Jarvis's snare. These forceps had been used by him extensively, and with gratifying results.

Two forms of nasal tumor, not mentioned by the author of the paper, were alluded to. First, that of cystic tumors of the nasal passages. This was a rare affection, but was worthy of notice, being of diagnostic importance. The speaker had met with but one case, and knew of but one in literature. Cystic tumors resembled exactly in their appearance gelatinous polypi. They differ from the latter in that in operating after seizing with the forceps, they are ruptured, and their contents escape. Under these circumstances, ordinary operators would continue to grasp for growths which did not exist, and hence might do harm. Dr. Lefferts stated that he himself had committed this error. The second form of nasal tumor sufficiently common to justify its mention was that of papilloma. These grew far forward. In several cases the speaker had seen them give rise to persistent attacks of epistaxis. It was a simple matter to put such a patient in a suitable light, and make an examination of the growth, upon detecting which, it could be readily removed by means of the forceps or scissors. He did not agree with Dr. Bosworth's statement, that interference with the singing voice was usually first noticed in the upper register. His experience had been that the middle register was the first to be affected. This, however, was a subject the discussion of which the limits of his remarks would not permit him to enter into.

DR. BRANDEIS wished to take issue with the author's statement regarding the use of the galvano-cautery. He had used it for a number of years past, and had thus far not met with any of the evil consequences described by authors. He had never had any affections of the middle ear resulting from its use, nor sufficiently extensive cicatrices to cause malposition of normal parts. The offensive discharge which was incidental to this method of operating was of only temporary duration, and of trivial annoyance. He had removed tumors by this means through both the nasal and pharyngeal cavities. The removal of growths by means of the galvano-caustic loop was considered good practice for two reasons: it not only removed the growth at its base, but, by virtue of its intense heat, reduced the probability of a recurrence of the trouble to a minimum.

DR. LINCOLN thought there were many growths in the nasal passages, especially anteriorly, the evil results of which might be far-reaching. In regard to those in the posterior region, the necessity for operation depended entirely upon whether the consequences of their continuance were sufficiently great to impair the health or produce great discomfort. The discomfort would depend upon the size of the tumor, and the discharge in consequence thereof. A case of reflex asthenia, due to one of these small growths, was cited. The growth was so insignificant that its removal was only finally resorted to as a matter of experiment, and the result which followed its abolition was an entire relief from asthmatic symptoms.

Another evil effect which might arise from the presence of these growths was that of malformation of the chest produced in childhood. The speaker had seen a number of instances where no other explanation by which the production of this deformity could be accounted for than that it was due to faulty respiration, incidental to the presence of growths in the nasal passages. Children thus afflicted would have short breathing, and breathe with their mouths open, causing a sucking movement, and consequently an insufficient expansion of the chest.

He believed that the author of the paper intended to infer that no method other than the use of the snare afforded satisfactory results. Upon this point he must take issue with Dr. Bosworth. He had published a series of cases some years since, in which caustics were used, and where the results were eminently satisfactory. The Vienna paste was a substance which could be applied by any one, and was most certainly a successful method of removing growths from the nasal passages. He had often applied it to the tonsils in cases of their enlargement, and with satisfactory results, reducing the tonsils to their normal size in a short time.

Jarvis's snare was certainly a most excellent and serviceable instrument. For certain cases, he believed that there was nothing else that could be devised to take its place. It was the most useful instrument in his office. He, however, recognized that in many cases there were other means of obtaining satisfactory results. The tonsils, as a rule, become atrophied at puberty. In cases of enlarged tonsils, he applied boracic acid, and with the result of diminishing the size of the growth.

DR. ROBINSON remarked that most of the points which had occurred to him during the reading of the paper had been touched upon by those who had preceded him in its discussion. In regard to Jarvis's snare and the warm advocacy of its use by Dr. Bosworth, the fact remained that it was not the only instrument we could use for the removal of these growths. It was, however, undoubtedly the best instrument which could be selected for that purpose when the growths were of any considerable size. Of course, when they were small, flat, and sessile—and such cases were very numerous—they could be removed by the galvano-cautery, or scarification with Myer's knife, or a sharp curette. But for the large growth, as he had already stated, there was no method that could at all compare with Jarvis's. In two cases, where other methods had failed entirely, he had used the snare and readily removed the growth without great pain or much trouble.

There was one point which he thought was not sufficiently emphasized by the author of the paper, and that was that when these adenoid growths were of considerable size, a certain amount of air was sucked out of the Eustachian tubes during each act of deglutition. He believed that the extension of the inflammatory action up the tubes was the explanation of imperfect hearing following the development of these growths. It was a curious fact, however, that in some instances the hearing was notably affected, while in others it remained good, notwithstanding the existence of growths of considerable size.

DR. JARVIS being called upon by the Chair, it was learned that he was absent in consequence of sickness.

DR. BOSWORTH, in closing the discussion, commented upon the question as to whether it was desirable to operate for the removal of these growths in children under the age of puberty. He stated that these children were brought to us in a morbid condition. They were brought on account of the existence of permanent and annoying symptoms, from which they wished to be relieved. It seemed to him that it was our duty to relieve these symptoms if we could. There was an additional reason for such a practice, as he had already stated. These growths naturally have a tendency to involve the parts below, giving rise to throat and bronchial troubles. Furthermore, we were not at all sure, that they would disappear upon the patient reaching the age of puberty, inasmuch as one of the pathological specimens presented this evening was from a patient sixty years of age.

As to the question of the forceps or the snare, he would say that if one or two of the growths which he had presented this evening were carefully inspected, it

would be seen that they bear the marks of the forceps. In fact, one of the growths which he presented had been chopped at with the forceps for three months by an expert, and had afterwards been removed by him by means of the snare. He had never seen a pair of forceps that could be made to reach the whole of one of these adenoid tumors. As to extension of catarrhal disease through the Eustachian tube, he could say that he had very rarely seen any evidence of catarrhal inflammation at the Eustachian orifices when inspecting them. His explanation of the interference of hearing due to the presence of these growths was not that they pressed upon the orifice of the Eustachian tubes and thus occluded them, but that, when of considerable size, they interfered with the action of the levator palati muscles which were concerned with the entrance of air into the middle ear.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, January 2, 1883.

THE PRESIDENT, E. C. SPITZKA, M.D., IN THE CHAIR.

PRESENTATION OF A SPECIMEN OF OCCLUSION OF BASILAR ARTERY.

DR. LEONARD WEBER first read the history of a patient who had died in consequence of occlusion of the basilar artery, which was, in brief, as follows:

The patient, a male, 42 years of age, and a merchant by occupation, had been, for a few weeks previous to his visit to Dr. Weber, feeling unnecessarily tired and weak. His appetite was diminished, he had occasional nausea, irregular action of the bowels, and frequent headaches of the nature of painful pressure on the top of the head; also, disturbed sleep. He came under observation November 9, 1878. On Nov. 21 he had not improved. He complained of vertigo and of a constant roaring noise in both his ears, and of increased pressure on the top of his head. In walking, he now dragged the right leg a little. The patient looking quite ill, a carriage was ordered for him, and he was taken home. Shortly afterward, he was found with paresis of the right upper and lower extremities, also right half of face and tongue. Eyesight was normal, as far as ordinary tests were concerned. He complained of vertigo, sickness, and increased pressure on the top of the head; no pain elsewhere. The patient gave a history of having had a primary sore on his penis twelve years previous, which, however, was not indurated, and was not followed by any secondary symptoms. He also gave a history of having subsequently had an ulcer upon his heel, which came without apparent cause, and remained open for a long time. Finally, under the influence of iodide of potassium, this ulcer healed. From these facts, it was supposed that his trouble now was probably due to syphilis, there being no other evidence of other organs being diseased which might cause embolism or cerebral apoplexy. At 2 P.M., Nov. 22, the patient was taken with a terrible fit of general convulsions, lasting several minutes. After the first attack the patient lost consciousness. These attacks were repeated every half hour, and the patient died in deep coma at 10.30 A.M.

A post-mortem examination twenty-four hours afterwards revealed no evidence of disease of the larger arterial branches until coming in contact with the basilar artery. This vessel was found completely filled with a firm clot extending from the place of union of the two vertebrals, about half an inch upwards. Upon making a longitudinal section, a small dense tumor growing from the inside of the walls of the right vertebral was cut through just at the junction with its fellow, and almost completely obstructing the lumen of the basilar artery at its very commencement. A microscopic examination revealed the fact that the tumor was composed of small cells and connective tissue, corresponding in its character to similar gummatous affections of cerebral vessels as described by several authors.

DR. WILLIAM A. HAMMOND then read a paper on

ALLOCHIRIA, ITS NATURE AND SEAT.

The case reported was one which Dr. Hammond saw in November in conjunction with Dr. L. A. Stimson. It was asserted that the patient had received a serious injury to the spine. In a day or two after the accident, symptoms indicating spinal trouble began to develop. Some time afterwards a physician was consulted, who diagnosticated Pott's disease. A plaster jacket was applied. Several months elapsed, during which he was at times better, and at other times worse. Upon the whole, there was no decided improvement. The fact that he had brought an action for heavy damages against the city was the immediate cause of Dr. Hammond's examination. Dr. Hammond was of the opinion that the patient had never suffered from an injury of the vertebral column or of subsequent Pott's disease. This opinion was concurred in by Drs. L. A. Stimson, Hamilton, and Clymer. The patient complained however of pain throughout the whole spine, and of excessive nervous irritability. He had had contractions of the muscles of the lower extremities, and on causing him to walk about the room, it was evident that his limbs were stiff and that he lifted his feet with difficulty. His gait was not that of locomotor ataxia. Up to this time, no experiments had been made with a view of testing the sensibility of the lower extremities. These were now denuded of their clothing, and the patient was told to shut his eyes. The touch of a finger, the scratch of a pin, or a deep puncture with the blade of a penknife, was equally unfelt in the right leg. On making the like experiments on the left leg, he complained of pain when the knife was stuck into it and automatically carried his hand to the place where he supposed the puncture had been made, but instead of touching the spot injured, he indicated the exactly corresponding situation on the other leg. Repeated experiments led to like results. The conclusion was reached, that the patient was suffering from antero-lateral or lateral sclerosis, with the implication of the posterior horns of gray matter, and probably of the membranes of the cord to a slight extent.

It was with reference to this cross sensibility which the patient exhibited that Dr. Hammond's paper was concerned. To this condition the name of allochiria has been given by Prof. Obersteiner, of Vienna, who was the first, so far as Dr. Hammond knew, to call especial attention to the phenomenon, though it had been incidentally alluded to by Leyden and Ferrier. In a post-mortem examination of one of Obersteiner's cases it was found that there had been inflammation of the first, second, and third lumbar vertebræ, meningitis, and extensive transverse inflammation of the cord. The posterior columns for a considerable distance above the seat of the injury were in a state of sclerosis, and the posterior horns of gray matter in portions of the cervical enlargement were transversely divided by a peculiar, structural, transparent mass intensely colored by carmine, and very similar to the mass which is found around the larger vessels in inflammatory processes in the cord.

Dr. Hammond was of the opinion that the lesion above described of the posterior horns of gray matter was that to which the phenomenon of allocheria is to be ascribed. Obersteiner and Ferrier had declared their inability to give an explanation of the mechanism of

the production of allochiria. Preparatory to an explanation of this symptom, Dr. Hammond referred to the fact that the posterior tract of gray matter was probably the only channel by which sensory impressions reached the brain, the posterior columns having in their normal condition nothing whatever to do with the transmission of such impressions. But, before reaching the posterior horns, the posterior roots of the spinal nerves pass through the columns of Burdach, and when these are the seat of inflammation, as they are in locomotor ataxia, disturbances of sensibility, such as hyperæsthesia, paræsthesia, and anæsthesia are produced in the parts below by the pressure exerted upon the roots. It was quite certain that there is an almost complete decussation of the sensory fibres within the gray matter. We were taught these facts not only by experimental physiology, but also by the instruction we derive from the study of cases of disease or injury of the cord. A diagrammatic representation of a section of the cord was then displayed and an explanation given of the method by which the peculiar symptoms alluded to arose. Dr. Hammond stated that in those cases of disease or injury of the posterior horns of gray matter, whether they be primarily involved or secondarily, as in locomotor ataxia, in which allochiria exists, either the lesion must be unilateral, or, if both horns are involved, the lesions must be at different levels.

In the only case of allochiria in which a post-mortem examination has been made, and which has been referred to above, Obersteiner found, among other abnormal conditions, disease of both posterior horns of gray matter. The morbid process was not continuous, as it is stated that it was not perceived in all the sections. It was situated at the narrowest part of the posterior horns, being so placed as to interrupt the decussation of all the nerve fibres, and hence to cause a transmission of sensory impressions upward on the same side in which they entered—a condition which, equally with that which Dr. Hammond described, would give rise to allochiria.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday Evening, Dec. 14, 1882.

THE PRESIDENT, DR. JAMES TYSON, IN THE CHAIR.

A CASE OF MITRAL OBSTRUCTION, WITH SEQUENTIAL LESIONS.

DR. E. T. BRUEN presented this specimen, in which the auriculo-ventricular opening of the left heart is nearly occluded by an epiglottic-shaped enlargement of one of the leaflets of the mitral valve. The valve is very much thickened, and the focus of a considerable calcareous deposit. The orifice during life permitted a reflux of blood from the ventricle into the auricle. The left auricle is dilated and hypertrophied, so that its cavity is about twice as large as normal. The right ventricle is very much dilated, the walls of this cavity are less than half the normal thickness, and the ventricle must have had during life twice its physiological capacity. The tricuspid valves were insufficient. The considerable cardiac enlargement occasioned an increase of the area of dulness on the level of the third and fourth ribs, and to the right of the median line of the sternum. In children, the heart with similar enlargement encroaches upon the left pleural cavity to such an extent that the physiological inflation of the left lung cannot occur. Bronchial breathing is produced, audible posteriorly, while anteriorly, below the second interspace, no respiratory murmur is audible. In these cases when the complication of bronchitis occurs, the physical signs suggest a pleural effusion. Enlargement of the right ventricle, both in children and adults, causes a pronounced impulse at the epigastrium and occasions serious pain and inconvenience. The murmur heard during life, in the case from which this specimen was taken, indicated this lesion, both presystolic and systolic murmurs being audible. The second sound at the pulmonary artery cartilage was also much accentuated, owing to the repletion of that vessel with blood. The first sound over the right ventricle was very clear and distinct, as is common in these cases, but the first sound at the apex was obscured by the murmur. The patient from whose body these specimens were removed was a woman, aged 46 years, who had been subject to heart disease since 20. The immediate cause of death was pulmonary repletion with blood, which induced right-heart failure.

PERICARDIAL EFFUSION AND ADHESION OF THE PERICARDIUM TO THE APEX OF THE HEART MISTAKEN FOR HEART RUPTURE.

DR. J. T. ESKRIDGE presented the specimens, and said that in this case the physician making the autopsy actually considered the specimen to be one of heart rupture. The patient was an athletic young man, and had been perfectly well until a few days before he sought medical advice. He was under treatment for only twenty-four hours, suffering from cardiac pain and great prostration. He died suddenly and unexpectedly, when no one was near him. The attending physician, who made the post-mortem examination with no professional assistance, reported effusion in both pleural cavities, the pericardium distended with thin, non-coagulated blood, and a rupture of the left ventricle. Dr. Eskridge said that a careful examination of the heart, pericardium, adjacent glands, and portions of the larger bronchi, showed marked evidences of pericarditis and pleuro-pericarditis. The pericardium was adherent to the lower third of the heart, but the adhesions were recent and easily severed. The heart was not much enlarged, its valves were nearly normal, and its muscle firm. No rupture was found. He believed that the case was one of pleurisy and pericarditis with effusion, death taking place suddenly from mechanical interference with the heart and lungs. He thought that the most plausible explanation of the doctor's mistake in calling it a case of cardiac rupture was that, when severing the blood-vessels around the heart, blood flowed into the pericardium and mingled with the serous effusion. He did not think that a firm, non-fatty heart could rupture itself by its own contractions. If the pericardium was filled with effusion in that instance, it taught a lesson of far more practical value than a case of cardiac rupture under similar circumstances would. It was evident, if the pericardium should be attached to the apex of the heart in a case of pericardial effusion in which operative interference was determined upon to free the heart's action, a thrust of the trocar into the pericardium would greatly endanger the ventricular walls.

SEVERAL SPECIMENS OF EYES ENUCLEATED ON ACCOUNT OF SYMPATHETIC IRRITATION IN THE OTHER EYE, OR FROM FEAR OF ITS DEVELOPING,

were exhibited by DR. LITTLE, who said that sympathetic irritation and sympathetic ophthalmia are the only two forms of the sympathetic diseases of the eye that afford an opportunity for pathological study, and in these cases only the enucleated eye can be investigated. Just what are the conditions in the remaining eye must remain uninvestigated. If full restoration of the function of vision is attained, great satisfaction only is felt. Less and less opportunity is being afforded of studying the condition of an eye enucleated for sympathetic ophthalmia in the other eye, since

merely the sympathetic irritation of the sound eye impels the surgeon to enucleate the primarily affected eye before true sympathetic ophthalmia asserts itself. The portion of the eyeball which renders liable the development of this affection when diseased is so well known that not even sympathetic irritation should be allowed to develop, as an early enucleation will prevent it. Enucleation of the primarily diseased eye when true sympathetic ophthalmia is present in the other eye is now questionable, as after all inflammation has subsided under treatment, surgical procedures upon the primarily affected eye may afford the best results for visual purposes. A recent experience will bear out this statement, the patient refusing the advice of a former medical attendant, and also my own, after two months suddenly developed sympathetic ophthalmia of the sound eye. Enucleation was then too late; now both eyes are becoming quiet, and I am in doubt which in the end will be the more available eye. A physician recently under treatment for a severely traumatized eye has refused the advice of two surgeons and is now doing well, but the danger of a sympathetically irritated eye is constantly before him. The pathological investigation is, then, mainly restricted to eyes enucleated before or after sympathetic irritation has developed in the other eye, as results show that under such circumstances full protection to the remaining eye is afforded. Investigation of eyes enucleated when sympathetic ophthalmia of the other eye is present may explain the cause of the trouble in the remaining eye, but there is so much damage done to both that our knowledge only makes us the more desirous to prevent these conditions from arising, and in the multiplicity of conditions the principal cause is lost. When enucleation to forestall sympathetic irritation is done, or when the operation is performed with sympathetic irritation just beginning or present, the eyeball removed is in a much better state to examine, and more light can be thrown upon the cause of sympathetic irritation, since severe inflammatory processes cloud the change from sympathetic irritation to that of sympathetic ophthalmia, and the pathological study is more difficult. My collection contains only one specimen enucleated when sympathetic ophthalmia was present, and in this case there was a double acute glaucoma, with sympathetic iritis.

At this time I only desire to place before you some specimens of eyes enucleated for the protection of the fellow eye from sympathetic irritation, or in which it was already beginning or developed; and in these cases good and permanent results have been attained. Four of these cases were due to traumatism, the fifth was of an inflammatory character. All but one of the traumatic cases had the fellow eye affected, and the examination of the enucleated eye in the exceptional case justified the operation. In two cases the sound eye became affected shortly after the injury to the enucleated eye. In one case, no irritation until forty years had elapsed since the accident to the enucleated eye. In one non-traumatic case, there were repeated attacks, for a series of years, of irritability in the sound eye, until the pain in the diseased eye, and the disturbance of the sound eye, compelled operation. In the remaining traumatic case, for twenty years the uninjured eye was unaffected, except rendering the myopia more progressive, which made an operation more imperative for its arrest, and to prevent the outbreak of sympathetic ophthalmia later in life. The patients were aged respectfully, three years, forty years, forty-seven years, fifty years, and seventy years. Three of the patients were males, and two females. In four cases the left eye was enucleated, in one case the right. In every case the injury or disease involved directly or indirectly the ciliary body; and where the crystalline lens remained *in situ*, or the sclerosed tissue infringed most markedly on the ciliary region, the irritation most rapidly in the other eye. Where the crystalline lens was dislocated with weakening of the sclerotic tissue, no irritation appeared for forty years in the other eye. In one case with dislocation of the lens, and detachment of the retina and choroid, no irritation had appeared at the end of twenty years in the other eye. In those cases where the iris became entangled in the cicatrix, sympathetic irritations of the other eye developed most rapidly, in one instance the lens becoming cataractous in the sound eye, while that of the injured one was either absorbed or lost at the time of the accident. In short, is it not to injury of the ciliary nerves, with their varied function, and to the damage done to the tissue in which they are imbedded in the different divisions of iris, ciliary body, and choroid, that we are to look as the cause of sympathetic irritation in the fellow eye; and of these, the ciliary body and nervous structures in it, with or without the involvement of the iris as the prineipal part involved? When sympathetic ophthalmia arises in the sound eye, can it not be traced to inflammatory processes added to the irritation of the ciliary nerves, and involving the iris, ciliary body, and choroid? How far the retina and optic nerve participate in the sympathetic irritation, it is difficult to say, only we find that in sympathetic enucleation for sympathetic irritation, the fellow eye regains the full function of sight. In sympathetic ophthalmia, however, the involvement of the nerves and retina is a more important factor, and the fellow eye is not so likely to be restored to full function of sight, as the conditions in the enucleated eye and in the one affected are more serious on account of marked inflammatory processes.

STAB OF PERICARDIUM, DIAPHRAGM, AND LIVER.

DR. STRITTMATTER exhibited three specimens, which were removed from a German laborer aged sixty-two, a patient in St. Mary's Hospital under Dr. Mears. He had been laboring for some days under a mental delusion, and after writing a clear, intelligible letter to his wife and family in Germany, stabbed himself with a clasp-knife in the right side of the chest several times. He was at once admitted to the hospital. He was much excited, with a rather flushed face, and but little shock. Examination showed two wounds—one over, and reaching down to the cartilage of the sixth rib of the right side, about one and a half inch from the sternal border, and about two inches in length; the other, half an inch from the border of the sternum, and severing from it the cartilage of the seventh and eighth ribs. Closer examination of this wound showed that there were two openings through the costal cartilages about a line apart, the outer passing downward, outward, and backward, the inner in a direction inward, downward, and backward. Through these openings air occasionally passed when the patient respired violently when struggling, causing a high-pitched sucking and blowing sound. None but slight bleeding took place, and that from the integument. Physical signs everywhere normal except over the lower part of the right lung, where increased resonance was noted, and on heavy percussion a kind of "cracked-pot sound" was elicited. Auscultation revealed diminished breathing sound over the upper part of the right lung, while respiratory sounds were entirely absent over its lower portion. Heart's action rapid and irregular; heart sounds feeble, especially the first; pulse, 112; respiration 42, and shallow. There was no sign of internal hemorrhage. Both during inspiration and expiration, when the head and shoulders were raised, and he inspired deeply, a peculiar high-pitched blowing sound was occasionally heard a little to the left and below the ensiform carti-

lage. It did not resemble the sound produced by gas in the stomach or bowels. Antiseptic dressings were used and morphia given, but he slept little, although nothing was complained of beyond a burning sensation beneath the sternum. The next morning he was calmer, rational, felt pain only during inspiration, and altogether breathed more easily than during the night, although the physical signs remained the same. The abdomen was tympanitic; the pulse full and moderately strong, 92 per minute; respirations 32, and expiration labored. During the next night grew worse. Friction sounds over the whole of the left chest, and on the right side from the apex to the fourth rib. Pericardial friction sounds were also heard. Pulse 100, full and hard; respiration 48, with rapid jerky inspiration, abruptly terminating, to be followed by a free, prolonged, groaning expiration; temperature, 103.2°. During the next twenty-four hours all the symptoms, physical as well as rational, of effusion into the pericardium and both pleuræ developed, but although the abdomen was tympanitic, no signs of effusion were detected. Pulse in evening 126, irregular and intermitting; respirations 40; temperature 101.8°. Had a bad night, and next morning appeared much prostrated, with a feeble, occasionally intermitting pulse of 120 per minute; temperature 102.8°; respiration 40, labored and shallow. Low, muttering delirium now set in; he sank rapidly, and died at 2 P.M. of the 20th, with a temperature of 105.5°.

Sectio cadaveris.—Brain: pia mater adherent, thickened in patches and opaque, especially on either side of the vessels, which were filled with dark blood over the upper convex surface of the left hemisphere. There was a slight amount of serous effusion in the subarachnoid space. The ventricles contained a small amount of serum. Chest: on raising the sternum the right pleural cavity was seen filled with a thick, fatty-looking effusion, with some bands of recent lymph, extending from the lung to the chest-wall. The apex of the lung was quite firmly adherent to the chest-wall. The anterior surface of the lung was covered to the depth of one-fourth of an inch with soft, grayish-yellow lymph. A portion of the back part of the inferior lobe was consolidated. The left pleural cavity was only about half filled with the same thick layer of lymph and adhesions of the apex that were noted in the right lung. No part of the left lung would sink in water. The pericardial sac was distended with fluid, and both upon its inner surface and upon that of the heart was abundance of lymph, connecting the two surfaces by drawn out bands of the same. There was a large chicken-fat clot in the left ventricle, extending about six inches into the aorta. The right ventricle was filled with blood, with a small clot extending into the pulmonary artery. Examination showed that, while there were but two penetrating wounds externally, the knife must have been thrust in repeatedly after partial withdrawal, as there were three openings through the diaphragm, penetrating the liver to the right of its suspensory ligament, and one traversing the lower part of the pericardial sac, and entering the left lobe of the liver for about one inch. The other liver wounds were one-fourth, one-half, and one-sixth of an inch deep. There were no traces of peritonitis, although about two ounces of serum were present, having probably escaped from the pericardial sac through the wound. The liver wounds did not gape; were united and surrounded for about an inch in every direction by a brownish-yellow discoloration. The liver weighed sixty-two ounces. Spleen enlarged and soft; other organs healthy.

DR. MEARS said he was much interested in this case. During life the symptoms of wound of the diaphragm and of the liver were markedly absent, whilst those of injury of pericardium and pleura developed as the interval after the receipt of the wounds increased. The external wounds gave little indication as to the direction taken by the knife after puncturing the thoracic cavity, and, as shown by the post-mortem examination, no information as to the extent of injury inflicted. The absence of symptoms of injury of the diaphragm may be explained by the fact that the wounds were in the tendinous portion of that muscle, and being small did not interfere to any great extent with its function in respiration. In injuries causing laceration of the muscular fibres attached to the ribs dyspnœa occurs as a prominent symptom, by reason of the impairment of the respiratory duty of the muscle. Moreover, the symptoms may have been masked by those referred to the injury of the pericardium, as in wounds of both of these structures dyspnœa is a prominent symptom. The knife in one of the thrusts passed through both, and involved them in a common injury. The only explanation I can offer of the production of the blowing or rather suction sound which was heard under the ensiform cartilage, is that it was occasioned by the passage of air during respiration through the openings in the diaphragm—the air entering primarily the lung cavity through the external wound. The fact that the air did not pass in and out of the external wound during the act of respiration afforded good evidence that the lung was not wounded. The wounds of liver were of such character as to make little or no impression beyond what might occur as the result of injury to the coverings and superficial portions. Puncture of the liver with a trocar is infrequently performed with a view of evacuating fluids. Instances are reported in which no fluid has been found, and no harm has been inflicted by the tapping. Extensive laceration, the result of gunshot wounds or rupture following falls, produce characteristic symptoms of shock and internal hemorrhage.

SECONDARY SARCOMA OF HEART, LUNGS, AND GALL-BLADDER, FOLLOWING PRIMARY AMPUTATION FOR DEPOSIT IN THE FEMUR.

DR. WILLARD exhibited the heart, lungs, and gall-bladder of a female aged 21, whose right thigh had been amputated four months previously for a spindle-celled sarcoma of the lower end of the femur. The apex of the right ventricle was infiltrated with a sarcomatous mass which extended into a cavity among the columnæ carneæ, forming an irregular shaped body occupying one-fifth of the space. The walls were softened. The diseased tissue was very soft and easily detachable, rendering its propulsion into the lungs a matter of exceeding probability at each heart-beat. The walls above the mass were natural in appearance and in thickness; the valves showed no evidence of disease on either side of the heart. The left ventricular and both auricular walls were healthy. The disease had not reached the visceral layer of the pericardium, and there was no abnormal effusion in the cavity of the sac. The septum ventricularum was not involved. That numerous particles had been swept into the lungs was very evident when these organs were examined. At a large number of points in either lung were to be seen white masses, varying in size from that of a pin's head to that of an English walnut. Some of these were dense, others were undergoing softening, and in nearly every instance the lung substance surrounding was so disintegrated that the mass seemed to be in a cavity containing a drachm or more of sanguinolent fluid. A very moderate degree of pressure would cause a nodule near the surface to burst its pleural covering and give rise to an accident similar to the one which was found to have occurred near the right apex. At this point a large sarcomatous mass

had excited a degree of inflammation sufficient to fasten the lung to the parietal pleura, and one week before the patient's death, ulcerating through the serous covering, had given rise to an internal hemorrhage that was well-nigh fatal, and gave the symptoms of sudden collapse noted in the history. This escaped blood was found in the right pleural cavity confined by adhesions chiefly to the upper portion of the chest. In the week which elapsed between the hemorrhage and death, it had coagulated, formed chicken-fat clots and other coagula weighing fully two pounds. The pleural cavity below the adhesions contained about two quarts of bloody serum. There was no consolidation of the lungs save around the diseased foci. The lungs had evidently acted as a complete strainer and had prevented the passage of emboli, for liver, kidneys, spleen, and all other organs were healthy save one small spot in the gall-bladder. The brain was not examined. The primary disease in the femur had apparently resulted from traumatism, since no difficulty had existed previous to a severe fall upon the knee. From this time the pain on walking was continuous, and four months later there was decided enlargement of the external condyle and swelling in the popliteal space.

The chief points of interest in the case were: *First*, the traumatism acting as an exciting cause. *Second*, that the physician who first saw her detected neither fracture nor luxation, nor anything beyond contusion of the joint. *Third*, the appearance at the end of four months of a pulsating tumor in the popliteal space, which presented a decided bruit, but no thrill. This was due to the lifting of the artery from its bed by the sarcomatous mass. *Fourth*, the non-involvement of the knee-joint, although the nodules had pushed forward the synovial membranes between the condyles posteriorly. The articular cartilage of the femur was intact, although the bone tissue immediately beneath it was extensively diseased. *Fifth*, the return of the disease, not in the stump in the right ventricle, and the failure in circulation and great prostration which came on from four to six weeks after the amputation, and without anything in the condition of the stump to warrant such depression. The patient seemed in *articulo mortis*, yet there was no pain and no dyspnœa, only a feeble rapid heart action accompanied by low delirium and weakness. There were no valve sounds audible. These symptoms were due, as shown post-mortem, to the deposit and development of the sarcomatous mass in the heart. Nature, however, gradually accommodated herself to the new growth, and the patient rallied for a time, so as to be able to walk on crutches, eat heartily, and consider herself in good health. She got fatter, and only slight dyspnœa on exertion, with three or four coughs a day, remained to indicate recurrence of the disease. *Sixth*, a sudden, causeless as to exertion, profuse hemorrhage, from the collapse incident to which she rallied and lived one week, with respiration 30–36, pulse 130–140. *Seventh*, the primary and consecutive growths showed a preponderance of spindle-cells, while the secondary nodules were composed chiefly of round cells. *Eighth*, the post-mortem examination throws great light upon the clinical symptoms, while the great rarity of sarcoma of the heart makes it important to note that there was never any angina pectoris. In Dr. Ingham's report of a case called carcinoma of the heart in the *Transactions* of this Society for 1877, the only case ever presented to this Society, angina pectoris was indicated as one of the diagnostic points. In the report of the Committee on Morbid Growths, Dr. Ingham's specimen was shown to be really an alveolar sarcoma. Secondary sarcomatous growths of the heart are mentioned by various authors, but the histories give no clinical signs of the growth.

DR. BARTON said that in regard to traumatisms causing morbid growths, he considered that they probably had no more causative effect than acting as exciting causes.

DR. FORMAD asked if the exact nature of the primary growth was known; whether it consisted of round or spindle-cells, since it has been stated that the spindle-celled variety never form metastasis.

DR. SEILER replied that the primary growth consisted of both round and spindle-cells.

DR. SHAKESPEARE agreed with Dr. Barton as to the origin of the primary growth. He did not believe that injuries were anything more than exciting causes in those predisposed to such growths. The case presented a typical example of the method of metastasis; we have the growth first developing at the knee, whence particles were carried by the veins to the heart, becoming there lodged, and developing into a tumor, which formed a new centre from which microscopic emboli were carried by the blood-current into the lungs, where they lodged and grew into the nodules seen in the specimen. Metastasis of sarcoma occurs by means of the blood-current, while that of carcinoma takes place through the lymphatics.

DR. FORMAD could see no other cause for the tumor than the injury of the knee, previous to which the patient had never shown any symptoms of disease of the joint, while shortly after receiving the injury the tumor appeared. The tumor may not necessarily be malignant; there is an inflammation and the formation of cells; the malignancy will depend upon the looseness of the cells, and the facility with which they can be transported.

DR. L. R. MILLS then read a paper on the *Brain in Epilepsy*.

DR. BRUBAKER presented a specimen of *Tumor of the Brain*, which, with the accompanying paper, was referred to the Committee on Morbid Growths.

CORRESPONDENCE.

COLOR-BLINDNESS.

To the Editor of THE MEDICAL NEWS.

SIR: On page 712 of your December 23d number you have quoted a notice from the *British Med. Journ.* of November 16th, in relation to the examinations of Dr. Kolbe and other Russian physicians for color-blindness. The article speaks of the very great variation in the percentage found by different observers among railroad employés, varying from 0.85 to 5.00. It does not, however, include Dr. Kolbe's explanation, which he gives in reporting the Russian statistics in the *St. Petersburgh Med. Wochenschrift*, October 23, 1882. This is important for us just commencing the testing on the railroads of this country. It seems that the three gentlemen who found so few color-blind were "sold" by the defective employés getting some normal-eyed to personate them during the examination. Dr. Kolbe wrote me that he had heard this from these gentlemen, and as it has now been proved he publishes it. Thus all criticism as to extraordinary variation in percentage, and consequent doubt as to the observer's skill or the reliability of the method used, falls to the ground. The great value of Holmgren's test is shown by the very uniform results experienced and competent examiners obtain by its use. It and all other methods are useless in the hands of the laity or the inexperienced physician.

Respectfully yours,

B. JOY JEFFRIES, M.D.

BOSTON, 15 CHESTNUT ST.,
December 30, 1882.

POLYGONUM HYDROPIPEROIDES.

To the Editor of THE MEDICAL NEWS.

SIR: In the MEDICAL NEWS of December 9, I find a short notice of *Polygonum hydropiperoides*, as given in Eberle's *Materia Medica*.

Dr. Eberle says it was brought to his notice by a country practitioner who made it his thesis subject. This was while Dr. Eberle was Professor of Theory and Practice in the Medical College of Ohio, and the country doctor was one Bud Eastman, then practising in the village of Paris, Jennings County, Indiana.

The writer was personally acquainted with Dr. Eastman, and has frequently heard the doctor speak of his thesis upon "*smart weed*." If there is any credit due any one for its introduction into our therapeutics, it is to Dr. Eastman, who was a man of more than ordinary ability in the profession—a safe, careful practitioner. He finally fell in with Millerism or second adventism, became a noted lecturer, drifted south, and died in Texas some twenty years ago.

The writer has practised medicine thirty-three years, and during this time has prescribed the *Polygonum* many hundred times, and has ever found it an emmenagogue of rare virtue. J. W. CONWAY, M.D.

MADISON, IND., December 15, 1882.

A CARD FROM MESSRS. W. H. SCHIEFFELIN & CO., OF NEW YORK.

To the Editor of THE MEDICAL NEWS:

SIR: In your issue of Dec. 16, 1882, you publish an article giving the results obtained by "an expert analytical chemist" (name and fame to us unknown) in the analysis of quinine pills.

We wish it distinctly understood, at the outset, that we are in favor of a most rigid examination of all chemical and pharmaceutical productions, whether of our make or of others, and we do not doubt that your wish is to do justice to all. But we assert that the value of analyses of complex organic mixtures, like pills, depends very largely upon the previous training and experience, as well as the good name and reputation, of the analyst. An analysis not accompanied by the name of the analyst as a pledge of good faith, has no more value than has an unsigned bank check. It is worthless.

Before criticising in detail the methods and results upon which you base your charge, that we, among others, are either careless or dishonest, and are furnishing the trade with short weight quinine pills, we wish to state that *the charge is not true, so far at least as we are concerned*, and we have positive proof to substantiate our statement.

We ask now that we may be allowed to correct some of the erroneous statements which appear in your article, as well as to record some of our objections to the methods of analysis. For convenience of reference we will classify our remarks.

I. A FAULTY METHOD OF ANALYSIS.

Twenty pills were taken for analysis. They should contain 40 grains of sulphate of quinine $(C_{20}H_{24}N_2O_2)_2.H_2SO_4.7H_2O$, equivalent to 29.725 grains of anhydrous quinine ($C_{20}H_{24}N_2O_2$), or 1.486 grain per pill of anhydrous quinine. The analyst recovered 1.420 and 1.424 (average, 1.422) grain of anhydrous quinine from each of our pills; he failed to recover 0.064 grain of anhydrous quinine from each of our pills, a quantity equivalent to 0.086 grain of sulphate of quinine. Failing, therefore, to recover 1.28 grain of anhydrous quinine in a total amount (in 20 pills) of 29.725 grains, you see fit to charge us with not putting in the full amount. In reply we would say that *the method of assay which was used is not one which will allow all the quinine present to be recovered.*

1. *The use of excess of ammonia as the precipitant was unfortunate.* It has been repeatedly shown that quinine is nearly insoluble in solution of soda, more soluble in solution of potash, and very soluble in ammonia. Because of this greater solubility in ammonia the Pharmacopœia (p. 160) directs the use of solution of soda in the assay process for quinine in the scaled salt, *Ferri et Quininæ Citras*. Again, Kerner's test for the purity of sulphate of quinine, now prescribed by the U. S. Pharmacopœia (p. 279), depends upon this very solubility of quinine in ammonia. It is certainly very difficult, if not practically impossible, to remove quinine completely from a solution containing excess of ammonia. In this method of "shaking out" an alkaloid by means of some solvent, the wider the differences in solvent power of the liquids present the more complete the extraction; hence soda would have been a very much better precipitant than ammonia. This statement is corroborated by our own frequently repeated laboratory assays of the scales referred to above.

2. *The use of ether as a separative solvent was also unfortunate.* In selecting a solvent for "shaking out" methods of assay two points must be carefully guarded.

a. The substance should be very much more soluble in the new solvent than in the alkaline liquid from which it is to be extracted.

b. The new volatile solvent should itself be as nearly insoluble as possible in the alkaline liquid.

Neither of these conditions is fulfilled by ether. Pure stronger ether is soluble, according to Dr. Squibb, in eight times its volume of water. Therefore, in any "shake method" of assay, the lower aqueous layer will surely be fully saturated with ether, which latter, in turn, will hold in solution a very perceptible amount of quinine. For this reason many experienced analysts, and notably the U. S. Pharmacopœia (p. 160), favor the use of chloroform.

For the extraction of quinine from uncomplicated aqueous solutions containing excess of soda, no solvent which we have used can compare with chloroform; it is a better solvent for quinine than is ether, and is more nearly insoluble in alkaline solutions (see articles Æther Fortior, Chloroformum Purificatum, and Quinina, U. S. Pharmacopœia, 1880).

3. *The test with potassio-mercuric iodide, as here described, could not fail to give a false indication as to extraction of the quinine.* Quinine is precipitated by this reagent only in neutral or acid solutions; the precipitate so produced is soluble in ammonia. This test, therefore, applied to the "remaining aqueous" (ammoniacal) "liquid" is absolutely worthless as regards the quinine present. On the other hand, gelatine, if present, could hardly fail to be precipitated by Mayer's solution whether quinine were present or not. (*Vide* Prescott's *Proximate Organic Analysis*, pp. 139, 140.)

4. *No allowance is made for experimental errors.* We have shown that the analytical process is one subject to several serious errors, and that, with the most conscientious attention to details of manipulation, the analyst cannot fail to leave unextracted a notable quantity of quinine.

A proper regard for the rights of the parties accused should have prompted the analyst to determine exactly the limits of error to which his process was subject. We can only account for this oversight upon the supposition that the difficulty of extracting quinine from complex mixtures was not fully appreciated by the "expert" employed.

II. MATHEMATICAL ERRORS.

You have seen fit to condemn various firms, and, in our case, the analyst's failure to extract $\frac{8}{100}$ grain of quinine from each *two*-grain pill, is his reason for charging us with dishonesty or inexcusable negligence.

In matters of this importance, where every $\frac{1}{100}$ grain has great weight in determining our honesty or dishonesty, we have a right to demand that simple mathematical calculations shall be correct. And if we shall show that the analyst has made several errors, we have a right to infer that he himself has been careless.

We beg to point out the following errors:

Manufacturers.	Series.	Analysis.	Anhydrous Quinine.	Analyst's Equivalent Sulphate of Quinine.	Correct Equival-nt Sulphate of Quinine.	Analyst's Error.
W. H. Schieffelin & Co.,	I	VII	1.42	1.91	1.91	0.00
W. H. Schieffelin & Co.,	II	III	1.424	1.91	1.92	0.01—
Keasbey & Mattison,	III	II	1.42	1.92	1.91	0.01+

It is very peculiar that 1.42 grain of anhydrous quinine should in one case be equivalent to 1.91 grain of sulphate of quinine, and in another case to 1.92 grain, while 1.424 grain of anhydrous quinine represents only 1.91 grain of sulphate of quinine.

We do not care to quibble over $\frac{1}{100}$ grain, and we would not, were it not that we are judged by hundredths-grains, but we refer to the above to show that the *analyst has been careless in making calculations.*

III. MISLEADING COMPARISONS.

We wish to call attention to a singular and very unfair comparison of one sample of pills containing bisulphate of quinine with six samples containing sulphate of quinine.

In speaking of "quinine pills" it is always, and very properly, understood that the pills contain the ordinary medicinal sulphate $(C_{20}H_{24}N_2O_2)_2.H_2SO_4.7H_2O$, a salt containing 74.31 per cent. of anhydrous quinine. Bisulphate of quinine is quite another salt, as appears from its chemical formula, $C_{20}H_{24}N_2O_2.H_2SO_4.7H_2O$.

Now, bisulphate of quinine contains only 59.12 per cent. of anhydrous quinine, and the injustice of your comparison appears in this, that, to those not chemists, you apparently affirm that 1.24 grain of anhydrous quinine represents more "sulphate of quinine" than does 1.42 grain of anhydrous quinine (Table, p. 690). 1.24 grain of anhydrous quinine is in reality equivalent to 1.67 grain of ordinary sulphate of quinine, as appears from the following proportion:

$$74.31 : 100 = 1.24 : x \qquad x = 1.67$$

In your conclusions (I., p. 691) you speak of seven samples of pills, five of which "*have not in them the amount of* SULPHATE OF QUININE *which they are represented to contain.*" Any competent chemist knows that a comparison of pills containing salicylate of quinine with those containing the ordinary sulphate would be no more unfair and misleading than the comparison of bisulphate with sulphate.

And now, it is due to our friends in the drug trade who have so unhesitatingly recommended our pills to the physicians, and due also to the great number of the medical profession who have become accustomed to administer them with implicit confidence, that *we repudiate the imputation which has been put upon us of either carelessness or dishonesty.* We do deny emphatically that the pills tested were short weight. We have shown how the analysis might have failed in finding a true result from imperfections in its method. We now assert that the analyst was at fault in regard to our pills.

1st. Because *we know* that the full weight of sulphate of quinine was put in them.

2d. Because, since the publication of your article, we have examined the record of our production of them as far back as the 1st of July, and find that the variation between the quantity of sulphate of quinine used, and the corresponding number of pills produced amounts to a mere fraction of one per cent., a degree of accuracy unattainable in extemporaneous dispensing. Pills made to order on physicians' prescriptions can be divided with only approximate exactness, and to make correctly only a few granules at a time in minute subdivisions is an impossibility. With us the liability to error is reduced to a minimum, for the chances of mistake in one skilled person making 5,000 pills at once, as against one hundred persons making collectively the same number, are as one to one hundred.

3. We have repeatedly had them analyzed by Mr. H. B. Parsons, who is not unknown as a chemist, and they were found by him to contain sulphate of quinine in full weight.

In regard to the comparison of prices, we care nothing, and only refer to it in order to show where the compiler seems to be weak, and that is in exactness or in carefulness. A slight examination of the table will show that, while purporting to give retail prices, it has, in some cases, given wholesale long prices, and in others wholesale net prices, and is as misleading as are the analyses.

In conclusion we desire to call your attention to the fact that the injury which such a publication as the one under consideration is calculated to inflict on parties whose names are used in such a connection is not likely to be overcome by any reply which may be made, as in many cases the persons who may have read the first article will never see the reply, and, if they do, will perhaps not read it carefully; we trust, therefore, that your sense of justice will induce you to give this reply as general and wide a circulation as that accorded the original article.

Yours truly,

W. H. SCHIEFFELIN & CO.

NEW YORK, December 30, 1882.

[In reply to the above card, it seems almost unnecessary to state that the report of the results of our analyses of quinine pills was not put forth anonymously, but was published as the work of THE MEDICAL NEWS Commission, and "the good name and reputation" of THE MEDICAL NEWS is the guarantee of the trustworthiness of the results obtained.

It is unfortunate that Messrs. Schieffelin & Co.'s general denial of the accuracy of our analyses is not accompanied with that "positive proof" which they assume to furnish. Apart from a general assertion as to the quantity of quinine issued since July 1st—an assertion which we of course do not presume to question—their card resolves itself, when examined, into criticisms reflecting upon the analysis, and objections to the method employed. The several points of objection will, therefore, be considered *seriatim.*

As regards the statement that "the method of analysis was faulty" because: 1. "The use of an excess of ammonia as the precipitant was unfortunate." 2. "The use of ether as a separative solvent was also unfortunate;" the simple fact is that, by this means, the amount of quinine contained in a solution may practically be *fully* recovered.

That quinine is more freely soluble in ammoniacal liquids than in pure water, or in solutions of soda or potassa, and that it is more freely soluble in chloroform than in ether, are facts which were considered to be so well known as to render any allusions to them unnecessary.

That ether is soluble in water to the extent mentioned was not overlooked in the making of our analysis. It is, however, plainly evident that the amount of quinine held in solution by the ether dissolved in the water must of necessity be reduced to an inappreciable amount, when the relative volumes of the aqueous liquid and ether employed are considered, and when the aqueous liquid is repeatedly shaken with fresh portions of ether and the ethereal layer in each instance is carefully separated. That the quinine is thus as completely recovered as is possible by any method of assay, is believed to be satisfactorily proven by the application of the test with potassio-mercuric iodide.

To the statement that "the test with potassio-mercuric iodide, as here described, could not fail to give a false indication as to extraction of the quinine," the answer is that the conditions attending the application of this reagent as a test for alkaloids were perfectly well known to our Commission, and the statement was not made in the report that the *ammoniacal* liquid was directly subjected to the test. The "remaining aqueous liquid," as stated in our report, was, indeed, tested; but not, however, without having been previously supersaturated with an acid; a condition which was considered so well known to chemists as not to require specific description.

The Messrs. Schieffelin further state that "for the extraction of quinine from uncomplicated aqueous solutions containing excess of soda, no solvent which we have used can compare with chloroform; it is a better solvent for quinine than is ether," etc. etc.; and further, the supposition is expressed "that the difficulty of extracting quinine from complex mixtures was not fully appreciated by the 'expert' employed." Now, it must be conceded that an aqueous solution of quinine containing considerable amounts of sugar, gelatine, etc., can *not* be considered an "uncomplicated solution," and that an amount of chloroform which would be sufficient readily to abstract the quinine from a pure solution, or one containing simple inorganic salts, would form, in the case of a solution thus complicated, a very viscid mixture.

The exactitude of the methods, and the avoidance of what Messrs. Schieffelin & Co. call "experimental errors," are sufficiently proved by the close coincidence of results arrived at in successive analyses, without any knowledge on the part of the operator as to the source of the specimens on which he was at work.

As considerable prominence has been given by Messrs. Schieffelin & Co. to the subject of "mathematical errors," and as they "demand" that "the mathematical calculations shall be correct," we presume that they will be satisfied when they see that such has been the case.

The discrepancy of $\frac{1}{100}$ grain in the tabulation of the result, which they supposed they had discovered, is attributable to the fact that in the second series of analyses, in stating the amount of anhydrous quinine, the third decimal was inserted, which was omitted in those of Series I. and III. The amounts of anhydrous quinine obtained by our Commission, extended to the third decimal, were as follows:

Manufacturers.	Series.	Analysis.	Anhydrous Quinine.	Equivalent of Sulphate of Quinine.
W. H. Schieffelin & Co.....	I	VII	1.422	1.914
W. H. Schieffelin & Co.....	II	III	1.424	1.916
Keasbey & Mattison.....	III	II	1.426	1.919

The statement criticised was, therefore, as correct as was possible within two decimals.

The Messrs. Schieffelin & Co. call attention to what they consider "a singular and very unfair comparison between bisulphate and sulphate of quinine pills," which, as stated by them, would mislead the reader into supposing that we had compared the amount of anhydrous quinine in these respective pills. It seems almost unnecessary for us to deny that we made any such comparison. The investigation by our Commission was solely to ascertain if the quinine pills on the market contained the amount of quinine sulphate, or bisulphate, as the case may be, which they were represented to contain, and the clear view of the result is not to be clouded by any extraneous issue. The reason why in the case of one house the bisulphate pills were analyzed was because that house sells and advertises to sell the bisulphate whenever quinine pills are called for, since they are believed to be more readily soluble than the sulphate.

As regards the comparison of prices, it is sufficient to remark that the Commission simply reported the prices which it paid, like any other retail purchaser. This is all that the profession and their patients are interested in; the questions of "wholesale long prices," and "wholesale net prices," are trade mysteries with which THE NEWS has nothing to do.—ED.]

BOSTON.

(*From our Special Correspondent.*)

DR. CARPENTER'S SIXTH LECTURE ON HUMAN AUTOMATISM.—This lecture, which concluded the course, considered automatism in morals. The lecturer began by stating the theory of pure automatism, as distinguished from his own theory of automatism controlled by the will, as follows: Man cannot be an exception to the general uniformity of nature; all his action is the result of what has gone before; choice is as absurd as in the case of a bar of iron between two magnets; "I cannot be other than I am; I cannot do otherwise than I do," is the automatist's creed. This position was then criticised as not taking account of human nature, which does not work in sequences as material forces do. The theory of a limited choice on the part of the human agent will explain all the facts brought forward by the automatists and many which their theory will not explain. A large body of moral experiences is utterly inconsistent with the automatist view. Now moral experience is determined by the original constitution and acquired habits. The habits are formed in youth, and the most important part of early training is that which relates to control of the bodily appetites and passions, as well as of the intellectual powers. As a proof of the freedom of the human agent, the lecturer dwelt upon the power of fixing the attention. He next considered the several motives which excite human action. First of all is the desire for air, which is so intense that persons never take their own lives by suspension of the breath, but by direct act of the will. But they overcome this desire by a flank movement, by means of muscles over which the will has more powerful control. Thus individuals commit suicide by holding the face in a basin of water, or by hanging when they could easily save themselves by touching the feet to the floor. Next ranks the desire for food. The influence of alcoholic drink was discussed, the lecturer saying that alcohol seriously modifies the constitution and its effect is hereditary.

Coleridge was cited as the most remarkable example of intellectual antomatism of the brightest type. But he lacked power of self-direction and was put under the control of a guardian. His son Arthur inherited his father's weakness, and was irresponsible for his unhappy end. Moral motives were considered, the dominant motive, according to the lecturer, being the desire to do right. But this motive varies greatly in clearness. In the case of street children, they apparently think that which they like is right, and that which they do not like is wrong. As an instance in point the Feejee Islanders were mentioned. Their morals have been regarded as nearly or wholly lacking, but an experienced observer has found that the Feejees have a strict sense of the weight of the *nomas* or law, and on their plane are rigid in their actions. In regard to morals the lecturer quoted the words which have been said to embody all morals: "I am, I ought, I can, I will." The first implies power of introspection. The second directs our attention to the consequences of our acts, and leads us to intensify their force by keeping the mind upon them. We possess the power of self-regulation in the power of control over our fixed character. By fixing our minds upon a lofty motive a flank movement may be made which shall defeat a base motive. No human power can be so strengthened by practice as this power of self-control. Every successful moral conflict leaves the victor so much the stronger—with so much the more good—for the next struggle. The best means to conquer temptation is to fix the mind upon some other object. It is bad policy constantly to say. "I will not yield to this," for then the object is kept before the mind; but the mind should resolutely be turned to some other thing. Instead of brooding over wrongs and the slights inflicted upon us by friends, the remedy is not to say: "I will not think of it," but to direct the mind into some other channel. Morose feelings, frequently, are the result of some bodily derangement, often of the liver. Nothing is worse than brooding. In periods of depression the lecturer had found much relief in reading Scott's novels. He concluded by saying that the moral automatism is largely under the control of the will.

THE APPROPRIATION TO THE ARMY MEDICAL MUSEUM AND LIBRARY.—We are glad to be able to announce that the House of Representatives, in the debate on the Army Appropriation Bill, has restored the appropriation for the Army Medical Museum and Library to the usual amount. The following is an extract from the *Congressional Record* of Jan. 4th:

MR. BUTTERWORTH.—In regard to that item, I will state to the Committee that it was reduced by the subcommittee on Appropriations from $10,000 to $7,500, and we had such a storm raised about our ears because of the fact that this is the pet of the whole medical profession, that after we had reduced it to that sum I moved to restore it to the amount of the estimate. The Committee on Appropriations, the whole committee, instructed, however, that this should be restored to $5,000. It has heretofore been $10,000. It relates to the collections made during the war, and stored in the Army Medical Museum, and for works of reference for the Surgeon-General's office; and I believe it is the finest collection possibly in the world. They insist that a larger sum is necessary. How it is necessary, however, was not made to appear, and the Committee instructed this reduction to be made.

MR. TOWNSHEND, of Illinois.—Let me ask the gentleman, if any consideration was given to the construction of a fire-proof building for the museum?

MR. BUTTERWORTH.—Yes. I will say to my friend this, that a part of the public building proposed to be erected for a library, would be devoted exclusively to this museum, and to the articles there gathered, together with the library.

MR. TOWNSHEND, of Illinois.—I have received communications from many persons, who speak of the library and museum as of great value, and of the necessity for the erection of a fire-proof building for their preservation.

MR. BUTTERWORTH.—There is no doubt of it. The gentleman is correct. It is asserted by many doctors to be one of the most valuable collections in the world; and it is now stored in what you might almost say is a mere tinder-box, liable to be destroyed by fire at any time. That is one of the reasons the committee deemed it unnecessary to add materially to the collection while it is in that building, but deemed it proper to withhold appropriations until a more suitable building was secured.

MR. TOWNSHEND, of Illinois.—Do the committee make any recommendations upon the subject?

MR. BUTTERWORTH.—The committee believe that a part of the new library building might be necessary for this museum.

MR. TOWNSHEND, of Illinois.—Does the gentleman think that it would be wise to separate the library from the museum? In my judgment they ought to be together.

MR. BUTTERWORTH.—The proposition was, to set apart a section in the new library building, to be devoted to the museum and its library.

MR. HEWITT, of New York.—Permit me to say that the amount, $10,000, appropriated last year was not, in the judgment of many eminent in the medical profession, sufficient. That, I suppose, the gentleman from Ohio understands. Five thousand dollars is entirely inadequate. This library is the most complete library in the world on medical subjects. The object is to complete it, and to keep it complete. Five thousand dollars a year will not purchase the new publications necessary to keep it up to its present standard. I think this is perhaps the wisest expenditure of money we can possibly make with reference to disease.

MR. BUTTERWORTH.—If the gentleman from New York will yield to me, I beg to state that I will move to increase the appropriation to $10,000.

MR. HEWITT, of New York.—That is right.

MR. TOWNSHEND, of Illinois.—I desire to say a word, unless the gentleman from New York (Mr. Hewitt) wishes to retain the floor.

MR. HEWITT, of New York.—I have finished what I had to say.

MR. TOWNSHEND, of Illinois.—I think true economy would require we should make provision for the preservation of the library and museum, and that a mere increase of the appropriation is not sufficient. I would suggest to the gentleman from New York (Mr. Hewitt) or the gentleman from Ohio (Mr. Butterworth) to bring in a provision here for the erection of a fire-proof building for the preservation of the museum and library.

MR. BUTTERWORTH.—I do not think that would be proper in this bill, although I agree with my friend from Illinois it is something which ought to be done.

The question being taken on the amendment offered by Mr. Butterworth, to strike out "$5,000," and insert "$10,000," it was agreed to.

CITIZENS' AUXILIARY SANITARY ASSOCIATION OF NEW ORLEANS.—According to the New Orleans papers a sanitary war is in progress in that city. It appears that the Auxiliary Sanitary Association, which was called into being by the sufferings of the city during the epidemic of 1878, and which since that time has labored to improve the sanitary condition by securing

clean streets, and the removal of all nuisances which are so apt to accumulate in an unsewered city, has recently made an effort to prevent the spread of smallpox by representing to the City Council the danger attending upon the usual burial service in cases of death from this disease. The association in the first instance offered to coöperate with the board of health to obtain appropriate legislation, but it does not appear that any action was taken by that body to meet the views of the citizens. One gentleman complained that a fatal case of smallpox occurred in the house which adjoined his own, and that no warning was given by the board of health. His first knowledge of the existence of the disease so near to his own household was conveyed by the funeral of the deceased. At a meeting of the board, a few days later, it decided that the association, instead of remaining "auxiliary," was becoming "*supersidiary*," and forthwith passed a resolution for its suppression. Nevertheless the association yet lives, and has tendered its support in the work of sanitation to the City Councilmen in an address, in which it adverts to some of the most important permanent works which have been accomplished by it.

SMALLPOX IN VIRGINIA.—A telegraphic despatch from Lynchburg states that smallpox has made its appearance at Salem, Roanoke County, and that thirty cases have already been reported. The neighboring towns of Roanoke and Wythville have quarantined against Salem, and other southwestern towns are considering the question of doing likewise. Roanoke College has suspended, and the students have gone home. The public schools have also closed, and business is at a standstill.

TROUBLE IN MCGILL UNIVERSITY.—A telegram from Montreal states that trouble has arisen in McGill University between the medical students and Dr. Wright, Instructor in Materia Medica. One hundred and forty-seven students demand the resignation of Dr. Wright, and threaten to leave the university if their demand is not complied with.

COMPLIMENTARY DINNER TO PROF. AUSTIN FLINT, SR.—Prof. Flint, who completes to-night his course of lectures before the Philadelphia County Medical Society, was entertained last evening at dinner at the Hotel Bellevue by a number of the prominent members of the medical profession of Philadelphia. Covers were laid for forty, and Prof. Alfred Stillé, President of the College of Physicians, presided, with Prof. Flint on his right and Prof. Gross on his left. Among those who participated were Dr. John L. Atlee, President of the American Medical Association, Drs. D. Hayes Agnew, Da Costa, Goodell, Bartholow, Austin Flint, Jr., S. Weir Mitchell, E. Wilson, A. H. Smith, W. V. Keating, Wm. Thomson, John Ashhurst, Jr., J. H. Brinton, I. M. Hays, and others. The arrangements of the dinner were under the charge of a committee consisting of Drs. Alfred Stillé, J. M. Da Costa, Wm. Pepper, S. W. Gross, James Tyson, Horace Y. Evans, and J. Ewing Mears. Towards the close of the dinner, the chairman proposed, in a few graceful remarks, the health of the distinguished guest, which was responded to by Dr. Flint in a feeling manner.

ELECTION OF OFFICERS OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY.—The annual meeting of the Philadelphia County Medical Society was held on January 3d, and the following officers were elected for the ensuing year:

President.—William M. Welch, M.D.

Vice-Presidents.—Drs. William R. D. Blackwood and Addinell Hewson.

Recording and Reporting Secretary.—Henry Leffman, M.D.

Corresponding Secretary.—H. Augustus Wilson, M.D.

Treasurer.—L. K. Baldwin, M.D.

Librarian.—C. M. Seltzer, M.D.

PROF. HENLE, the eminent anatomist, has been elected, in the place of the late Prof. Wöhler, as permanent secretary of the Royal Academy of Sciences, at Göttingen.

THE NEW YORK SOCIETY OF MEDICAL JURISPRUDENCE.—The newly organized New York Society of Medical Jurisprudence held its first public meeting last Thursday evening at the Academy of Medicine. Dr. J. S. Wight, Professor of Surgery in the Long Island College Hospital read a paper on the "Bearing of Illusions and Hallucinations on Testimony."

This society was organized last month. Its object is the "advancement and study of the science of medical jurisprudence and the attainment of a higher standard of expert testimony." It has a membership of more than one hundred physicians and lawyers. Among the prominent medical members are Drs. Meredith Clymer, T. E. Satterthwaite, Clinton Wagner, T. C. Finnell, C. S. Wood, W. A. Hammond, Nathan Bozeman, T. A. McBride, J. S. Wight, and L. C. Gray. The society will hold monthly meetings.

ABOLITION OF THE GRADUATION THESIS.—The Senate of Toronto University has abolished the statute which requires candidates for the degree of M.D. to write a thesis.

NEW YORK POLYCLINIC.—The attendance at the New York Polyclinic during its first course of six weeks has been such as to assure the success of the institution. Fifty-nine practitioners took out tickets, twenty-seven of these being in the Gynecological Department, and 1089 new patients were treated in the dispensary.

HEALTH IN MICHIGAN.—Reports to the State Board of Health by observers of diseases in different parts of the State, for the week ending Dec. 30, 1882, indicate that intermittent fever has considerably increased, and that scarlet fever, consumption, membranous croup, measles, and remittent fever have increased in area of prevalence.

Compared with the average for the month of December in the preceding five years, neuralgia, tonsillitis, and dysentery were more prevalent, and remittent fever, intermittent fever, diphtheria, bronchitis, consumption, and pneumonia were less prevalent during the month of December, 1882.

Including reports by regular observers, and by others, diphtheria was reported present during the week ending Dec. 30, and since, at 18 places, scarlet fever at 12 places, measles at 7 places, and smallpox at 2 places, as follows: at Richmond, Osceola Co., Dec. 27; at Ionia (one case), Jan. 3, 1883.

Three cases of scarlet fever are reported at Marquette among immigrants just arrived from England. The disease was contracted on the steamer.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 1 TO JANUARY 8, 1883.

MCKEE, J. C., *Surgeon.*—To report, on or before Jan. 1, 1883, to the commanding officer Fort Winfield Scott, Cal., for assignment to duty as Post Surgeon.—*Par. 1, S. O. 197, Department of California, December 28, 1882.*

GORGAS, W. C., *Assistant Surgeon.*—Relieved from the temporary duty to which he was assigned under par. iv., S. O. 137, Department of Texas, and will report to the commanding officer Fort Brown, Texas.—*Par. 2, S. O. 140, Department of Texas, December 26, 1882.*

THE adventitious sounds or râles produced by acts of respiration, and the vocal signs, will furnish the topics to be considered in this lecture.

MOIST AND DRY BRONCHIAL RALES.

The bronchial râles, moist and dry, were studied and explained by Laennec so completely and accurately that they need at the present time, in these regards, no modifications nor additions. Diversified as are the sounds, he reduced them to three signs, namely, the mucous (more correctly called the moist bronchial or bubbling râles), the sonorous, and the sibilant râles. These are distinct from the crepitant, the subcrepitant, and the crackling râles, which require separate notice. The crepitant and the crackling râles are distinguished as not bronchial but intra-vesicular in their source. It is interesting to contrast this simple division by Laennec with the over-refinement by Fournet. That author describes five varieties of intra-vesicular râles, five varieties of extra-vesicular râles, and four varieties of bronchial râles. Skoda aimed at simplicity in his division, but it is in striking contrast to the simple arrangement by Laennec. Skoda divided the râles which have been referred to, into: 1st. A vesicular râle; 2d. A consonating râle; 3d. A dry crepitating râle; and, 4th Indeterminate râles. The effect of this division and nomenclature is to substitute confusion and error for clearness and correctness. It is needless to mention here the physical conditions which the moist and dry bronchial râles represent. I will make one practical remark respecting the clinical significance of the moist or bubbling (or, as called by Laennec, the mucous) râles—namely, they are often wanting in bronchitis affecting the larger and medum-sized tubes, for the reason that adhesive mucus and solid sputa are not suited for bubbling. These râles occur when the bronchial tubes contain pus, serum, blood, or liquefied tuberculous deposit.

It is pleasant to find in Skoda's treatise a statement, with respect to these râles, of an important practical fact. I quote the statement referred to as follows: "The pitch of a râle generally corresponds to that of the respiratory murmur which is either replaced by or accompanies it." Again, "The acute, large, or unequal bubbling thoracic râles indicate the same condition of the lung tissue as bronchophony and bronchial respiration." The importance of this fact is perhaps not always appreciated by auscultators. It enables the auscultator to determine by the râles alone, if respiratory sounds be, as they sometimes are, absent, whether solidification of lung exists or not. For examples, the bubbling râles in capillary bronchitis and pulmonary œdema are always low in pitch, denoting non-solidification of lung. These râles are high in pitch in a lobe solidified by pneumonia or by a phthisical affection. It does not seem to me easy to explain this effect upon the pitch of râles by solidification of lung, but it is not less true, on that account, as a clinical fact determined by observation.

The moist bronchial râles are easily illustrated artificially as follows: Attach to a Davidson's syringe a long India-rubber tube, or a series of tubes differing in size. After passing a little water through the tube or tubes, bubbling sounds are produced by a current of air for several hours. To observe these the tube should be held close to the ear, and other sounds excluded by covering the ear and the tube with the palm of the hand. This experiment shows that a very little liquid is sufficient to produce much bubbling, and therefore the abundance of moist bronchial râles is not evidence of much liquid.

The dry râles, sibilant and sonorous, can be illustrated with India-rubber tubes, either attached to Davidson's syringe or using the breath, by contracting the tubes at certain points. This may be done by either applying ligatures or compression with a forceps. It requires, however, some pains to secure the precise amount of contraction of the tubes necessary for the production of whistling and snoring sounds. The experiment, thus, while it demonstrates the mechanism of these râles, is defective in some accessory physical conditions which are involved in their production in cases of asthma and bronchitis.

SUBCREPITANT AND CREPITANT RALES.

Laennec described a moist crepitant râle, a subcrepitant râle, and a dry crepitant or crackling râle. His descriptions, as far as they go, are exact, but he failed to draw a sharp line of distinction between the râles now well known as the crepitant and the subcrepitant. The error of attributing the crepitant as well as the subcrepitant râle to the bubbling of liquid, probably occasioned perplexity. The fact that the crepitant râle is heard with inspiration and never with expiration, would not occur to him as probable if both were bubbling sounds; hence he failed to recognize this important distinctive point. That he confounded the crepitant and the subcrepitant râle, seems certain; yet he regarded the crepitant râle as the pathognomonic sign of pneumonia. In this respect he was in advance of his commentator, Skoda, who declared that the crepitant râle is only occasionally limited to inspiration, and that "no distinctive line can be drawn between crepitating, subcrepitating, and mucous râles." This must seem a remarkable statement to the auscultators of to-day; at all events, to those of this country. Not less remarkable is Skoda's statement that he has not often observed, in cases of pneumonia the crepitant râle as described by Laennec.

The true explanation of the mechanism of the crepitant râle was first given by an American writer, the late Dr. E. A. Carr, of Canandaigua, New York, in a communication published in the *American Journal of the Medical Sciences*, in 1842. This explanation attributes it to the separation of the walls of air vesicles in

the act of inspiration, more or less of the walls having become *adherent* at the end of the act of expiration, from the presence of adherent mucus. It is probably more accurate to say that the sides of the ultimate bronchial tubes or bronchioles adhere at the end of inspiration, and are separated by the act of inspiration; hence, it is not strictly correct to call the crepitant râle a vesicular râle. It is not a bubbling sound, and the application to it of the term moist, is one of the few instances in which Laennec's observations were influenced by his reasoning. A true crepitant râle is characterized by dryness; but it is to be considered that Laennec did not discriminate sharply the crepitant from the subcrepitant, the latter being a moist or bubbling sound. After the lapse of forty years the explanation by Carr has made considerable headway as regards its general adoption. The explanation is so simple, it accounts for the peculiar characters of the sign so completely, and its correctness may be rendered so demonstrative by artificial illustrations, that it would seem as if it should at once have been adopted. Carr's imitation of the râle was by moistening the thumb and forefinger with a little mucilage, and alternately pressing them together and separating them, held close to the ear. As already stated, a crepitant râle may be obtained by auscultating directly a healthy lung after its removal from the body. The illustration is better after twenty-four hours than shortly after the lungs are removed. But the most perfect illustration was by means of an article made ten or twelve years ago, of India-rubber, to serve as a substitute for a sponge. This article was in structure like a very fine sponge; when compressed and then allowed to expand, holding it close to the ear, the representation of the crepitant râle was as perfect as possible. This illustration furnished demonstrative proof that the râle is not a bubbling sound, and that it is produced by the separation of adherent surfaces, for in using the article to illustrate the sign, not the least moisture was required.[1]

The subcrepitant râle may be illustrated with the lungs of the calf or the sheep. After having obtained, by application to the lungs of the binaural stethoscope, the crepitant râle, which, as has been seen, may be in this way illustrated, a certain quantity of liquid (water or glycerine) is to be poured into the trachea. Now, imitating respiration by inflating with the bellows, the subcrepitant râle is beautifully represented. The bubbling is extremely fine, and is associated with crepitation. It is heard with the current of air which represents expiration as well as that representing inspiration. A similar association of the crepitant with the subcrepitant râle is by no means uncommon in pneumonia, and is, perhaps, the rule in the resolving stage of that disease. It is probable that this fact contributed to Laennec's confusion as regards these two râles.

A recent theory attributes the crepitant, the subcrepitant and, indeed, other bubbling râles, to intra-pleural exudation and adhesions. The experiment just stated demonstrates the fact that each of these râles may be produced within the lungs removed from the body. Autopsical examinations in cases in which these râles have been observed during life, show the existence of physical conditions analogous to those in that experiment. The râles are found in cases in which examinations after death show no pleural exudation or adhesions. On these data may be based the assertion that the intra-pleural theory of the production of these râles is, to say the least, purely gratuitous. This is not saying that the stretching of fibrin, or of newly formed tissue between the pleural surfaces, may not sometimes produce sounds which simulate these râles. I cannot, however, think that the ear of an experienced auscultator can be thereby often deceived.

The pleural friction sounds with which every practical auscultator is familiar, have characters which are sufficiently distinctive. They are expressed by such terms as grazing, rubbing, creaking, grating, rasping, and not by bubbling or crackling. They are irregular in their connection with the respiratory acts, occurring with some and not with other successive acts; now heard in inspiration and now in expiration; sometimes at the beginning and at other times near the end of either inspiration or expiration; in some instances being continuous, in other instances interrupted or jerking, and not infrequently disappearing temporarily after repeated forced respirations. These are not characters in common with the crepitant or the subcrepitant râle. A highly distinctive feature is their apparent superficial seat. They seem to be produced directly beneath the ear applied to the chest, or the stethoscope. Râles produced within the air tubes or vesicles differ in this regard. Of the clinical significance and importance of pleural friction sounds, it is unnecessary to speak.

Laennec described a râle under the name "dry crepitant, with large bubbles or crackling" (*râle crepitant sec à grosses bulles ou craquement*). He stated, as a distinctive feature, that it is limited to the inspiratory act. He supposed it to be a diagnostic sign of pulmonary emphysema. There is an obvious incongruity in calling the sign a dry râle, with large bubbles. The term crackling is more definite. At the present day this râle is not generally recognized as a distinct sign. Skoda admitted its existence, but remarked, somewhat flippantly, that they who had failed to recognize it had not lost much. A râle such as Laennec described is the crackling at the summit of the chest, which is one of the accessory signs in the early stage of phthisis. It is sometimes heard at the summit of the chest on both sides in healthy persons at the end of a very deep inspiration. It is certainly not of much diagnostic value in pulmonary emphysema, but I have sometimes met with it occurring in connection with that affection. It has seemed to me to originate in the portions of lung not having become emphysematous. I have regarded it as an abnormal exaggeration of the vesicular quality of the inspiration in the normal respiratory murmur.

Metallic tinkling, a sign with characters so distinctive that it is recognized at once from a description of them, has given rise to diversity of opinion and much discussion in regard to its mechanism, there being no lack of agreement in respect of its clinical significance. Jacob Bigelow, in 1839, demonstrated by a few well-devised experiments that the dropping of liquid in a space containing liquid and air gives rise to the sign. This was Laennec's explanation. Bigelow, however, demonstrated that the sign was also produced by the explosion of bubbles on the surface of a liquid, within a cavity containing both liquid and air. This was the explanation given by Bean, Dance, and Spittal. These two explanations require the presence of liquid as well as air within either the pleural cavity or a pulmonary excavation. A third mode of production is the bursting of bubbles of air at the mouth of a fistulous opening into the pleural cavity, or at the point of communication of a bronchial tube with a pulmonary excavation. It is easy to demonstrate the correctness of each of these explanations. The sign may be produced by either of the three modes, and, clinically, each is applicable to certain instances. For this demonstration we may employ the India-rubber bag be-

[1] A similar article is now made and used by artists. Something, however, is combined with the India-rubber, making it better adapted for its use as a sponge, but impairing very much its fitness to illustrate the mechanism of the crepitant râle.

longing to the modern foot-ball, which has been found serviceable in illustrating tympanitic resonance on percussion, and amphoric respiration. If the opening into this bag be connected with an India-rubber tube of sufficient length, the bag partially filled with a liquid and inflated, metallic tinkling may be produced by holding the bag so that the opening is dependent, and causing bubbles at the surface of the liquid by introducing air through the tube from the mouth. It will be found that the quantity of liquid within the bag must not be large, otherwise gurgling is produced instead of the tinkling sounds. Tinkling sounds may be produced by making the other end of the bag dependent, and thus causing drops to fall from above to the surface of the liquid. Shaking the bag will also produce the sounds. Now, if the liquid within the bag be allowed to escape, and a few drops remain in the tube, on blowing into the latter and holding the bag close to the ear, excellent examples of this sign are obtained. This last experiment gives the best illustration, and it is probable that it exemplifies the most frequent of the modes in which the sign is produced clinically.

We are now to consider vocal signs, and, first, the signs which are incident to the laryngeal or loud voice.

The names bronchophony, pectoriloquy, and ægophony, applied by Laennec to vocal signs, are still, and will probably always remain, in common use. It is, however, conceded on every side that in the description and interpretation of the first two of these signs (bronchophony and pectoriloquy) Laennec's treatise is defective. It is evident, in reading that portion of his treatise which is devoted to these signs, that his mind was biased by the desire to establish pectoriloquy as a cavernous sign. According to his description of bronchophony, "the voice seldom traverses the stethoscope." In pectoriloquy, on the other hand, the voice traverses the stethoscope either wholly or in part. By this language he means, doubtless, that the voice in pectoriloquy seems to be more or less near the ear of the auscultator. The distinction is a just and good one, but, as will presently be seen, it is not characteristic of a cavernous sign. The confused idea in Laennec's own mind is shown by his division of pectoriloquy into three varieties, namely, perfect, imperfect, and doubtful. The last variety, as he admits, is not to be distinguished by its intrinsic characters from bronchophony. A doubtful physical sign can hardly have much clinical value, and, quoting from an essay by Oliver Wendell Holmes, "To speak of the tones of the voice being heard a *short distance up the stethoscope*, is to present to the student a distinction of such tenuity as must seem beyond the reach of his faculties."[1] The vulnerability of this part of Laennec's treatise did not, of course, escape the critical eye of Skoda; but, if it be correct to say there is confusion in the account of bronchophony and pectoriloquy by Laennec, there is "confusion worse confounded" in Skoda's description. Skoda, after distinguishing the normal variations of the thoracic voice by the terms, *loud*, *clear*, and *humming* (terms which are not very sharply distinctive), and after concluding that bronchophony and pectoriloquy are identical, makes the following abnormal varieties: "1. The voice, accompanied by a concussion in the ear, completely traverses the stethoscope—loud bronchophony, which may be either clear or dull. 2. The voice, unaccompanied by concussion in the ear, passes incompletely through the stethoscope—weak bronchophony. 3. An indistinct humming, with or without a barely appreciable concussion in the ear."

[1] *Vide* Prize Dissertation. Published by order of the Massachusetts Medical Society, Boston, 1836.

It will be observed that there is no provision for ascertaining these modifications by immediate auscultation—the stethoscope is essential. I can sympathize with the student or the practitioner who attempts to grasp the distinctions set forth in this quotation, and to apply them at the bedside. The perplexity is not diminished by reading all that the author has to say with a view to their elucidation in the pages which follow. Adopting Skoda's account of vocal signs, it is not to be wondered at that a late German author, to whom I have repeatedly referred—Eichhorst—thus introduces a chapter on auscultation of the voice: "Its diagnostic value has been much over-estimated. It hardly ever furnishes original diagnostic results, and, almost without an exception, its object is to confirm conclusions obtained by previous methods of investigation." I am sure that this quotation does not express the estimate in which the vocal signs are held in our country, as bearing on the diagnosis of pulmonary diseases.

How are we to determine the signs which are incident to the loud voice and their differential characters? There is but one way, and that is by means of the analytical method of study. This method requires, as the point of departure for determining the morbid signs, study of the thoracic voice in health. This study shows that if we except characters which in some healthy persons belong to the voice as transmitted over the extra-pulmonary bronchi, especially on the right side of the chest, the *normal vocal resonance* is low in pitch, the voice seems diffused and distant from the ear, and it is accompanied by a perception of more or less vibration, thrill, or fremitus, which is not an acoustic but a tactile sensation. It is important to discriminate the fremitus from the resonance.

BRONCHOPHONY.

Proceeding now to morbid signs as determined by analytical study, it is a highly distinctive abnormal deviation from the lowness in pitch, the distance and the diffusion of the normal vocal resonance, when the thoracic voice is raised in pitch, seemingly concentrated and near the ear. These characters are present when the voice is transmitted through solidified lung. Calling the sign distinguished by these characters bronchophony, it always denotes a certain degree of solidification of lung, if we except the so-called normal bronchophony sometimes found on the right side of the chest, and in rare instances on the left side, at the summit, over the extra-pulmonary bronchi in healthy persons. The abnormal sign is rarely wanting if the requisite degree of solidification of lung exist. It is not necessary, for the production of this sign, that the solidification be complete. It is obtained in pneumonia and other affections which involve solidification of lung, when the associated respiratory sign is not the bronchial, but the broncho vesicular respiration, and, of course, the normal bronchophony is heard over lung not solidified, its production being evidently due to the proximity of the large bronchial tubes. Observe that intensity of sound is not included among the distinctive characters of bronchophony. The voice may be either loud or weak. If the voice be concentrated, near the ear, and high in pitch, no matter how feeble the sound, it is not less bronchophony than if the sound were ever so loud, and the diagnostic significance is the same.

INCREASED VOCAL RESONANCE.

The vocal resonance may be abnormally loud, with no marked alteration either in concentration, nearness to the ear, or pitch. A simple increase of the resonance, therefore, it remaining low, distant, and diffused, is a vocal sign distinct from bronchophony, and which, as clinical observations in connection with examina-

tions after death show, represents solidification of lung. The solidification thus represented is not sufficient in degree to give rise to bronchophony. Increased vocal resonance, as distinct from bronchophony, is also a cavernous sign. This statement is based exclusively on my own observations. If a cavity of considerable size be situated near the superficies of the lung, and not surrounded by solidified pulmonary structure, the vocal resonance is notably increased, and may be extremely intense, without the characters which are distinctive of bronchophony. The sign is often associated with cavernous respiration, and but rarely with amphoric respiration, the latter sign requiring solidified lung around the tuberculous cavity.

PECTORILOQUY.

Pectoriloquy, from its derivation, signifies thoracic *speech* as distinguished from thoracic *voice*, bronchophony having the latter signification. Strange to say, Laennec, who introduced these terms, did not employ them in accordance with this etymological distinction. His description of pectoriloquy embraced only the transmission of the voice. The confusion which has always existed, and still exists, in the use of the terms pectoriloquy and bronchophony, is readily and completely done away with by the use of these terms in the true etymological sense of each. Bronchophony should be considered as meaning transmission of the voice, together with the characters which are distinctive of that sign. Pectoriloquy should be limited to the transmission of speech, that is, of articulated words, through the chest.

With this definition, Is pectoriloquy to be rejected as a superfluous sign, as is done by Skoda? By no means. There is no sign better individualized than this. It is easy to decide, in any instance, whether or not the speech, that is, articulated words, is perceived. There is one liability to error, namely, the auscultator may hear the words from the mouth of the patient, and fancy that he hears them through the chest. In order to avoid this error, if immediate auscultation be employed or an uniaural stethoscope, the ear which is not to receive the chest sounds should be effectually closed. This, by the way, is a precaution to be observed in listening to any of the vocal signs. To make assurance doubly sure as to the existence of pectoriloquy, the auscultator should not know beforehand the words which the patient speaks. I have been accustomed to use this precaution in giving practical lessons in auscultation, and I have been led to notice that some persons seize much better than others, words transmitted through the chest.

Is pectoriloquy a cavernous sign? It is, and it is not. Articulated words may be transmitted through a pulmonary cavity. It is then purely a cavernous sign. They may be transmitted through solidified lung; it is then, of course, a sign not of a cavity, but of solidified lung. Now, is it practicable to determine clinically, whether the sign denotes a cavity or not? I answer in the affirmative. The discrimination is easy. If the thoracic voice which accompanies the pectoriloquy have the characters which are distinctive of bronchophony, the transmission of speech is through solidified lung. The two signs, pectoriloquy and bronchophony, are conjointly present. If, on the other hand, the bronchophonic characters are wanting, and the pectoriloquy is accompanied by merely an increased intensity of the transmitted voice, the transmission of speech is through a pulmonary cavity. The two signs, pectoriloquy and increased vocal resonance, are then conjoined. There is, therefore, a cavernous pectoriloquy, and there is a bronchophonic pectoriloquy, the differential characters being well marked and easy of recognition.

ÆGOPHONY.

Ægophony claims but a few remarks, not meaning to imply that it is a doubtful sign, as regards either its distinctive characters or its significance, but because, owing to correlative signs, it might easily be dispensed with in diagnosis. In fact, now when the exploratory puncture of the chest is employed in diagnosis without reserve, the auscultatory signs of pleuritic effusion are of much less practical importance than heretofore. Recently cases have been reported and papers published to show that, by means of the transmission of the whispered voice, it may be determined whether liquid within the pleural space be purulent or serous; but why waste time in observations and discussions relative to this point of inquiry, when by means of a hypodermic syringe in less than a minute the character of the liquid can be ascertained demonstratively?

It is a curious fact that in Laennec's treatise more than one-sixth of the portion of the work occupied with the consideration of the physical signs obtained by auscultation, is devoted to ægophony. In the greater part of this space, however, he discusses the mechanism of the sign. No one has found fault with or improved upon his description of the sign, and the name is well applied to it in certain instances, although the cry of the goat is less familiar to the people of this country than to the citizens of Paris. I believe that Laennec's interpretation of the sign is the true one, without regard to his views of the mechanism. The sign denotes a certain amount of pleuritic effusion. From Skoda's statement that he has heard ægophony in cases of simple pneumonia, I infer that either the pneumonia was accompanied by the requisite amount of liquid within the pleural space, or that he confounded ægophony with bronchophony. Analytically studied, ægophony has the same characters as bronchophony, minus the nearness to the ear, added to which is the tremulous or bleating quality. The sound is more or less distant from the ear, and is rarely accompanied by fremitus. I believe the sound to be essentially a bronchophonic voice, rendered more or less distant, the fremitus suppressed, the other modifications being due to its transmission through a stratum of liquid. Hence, the physical conditions for its production, in a case of pleurisy, are, the presence of a certain quantity of serous or purulent effusion, and condensation of a portion of the compressed lung sufficient to give rise to bronchophony. The latter condition is likely to exist with a moderate amount of effused liquid when the upper third of the lung is adherent to the chest wall by either recently exuded lymph or old adhesions, and the compressing force of the liquid as a consequence is brought to bear on the lower two-thirds of the lung.

I have repeatedly endeavored to connect bronchophony with ægophony by placing between the chest and the stethoscope an India-rubber bag containing varying quantities of liquid, in a situation where the bronchophonic voice was marked, in cases of pneumonia. The pitch, of course, is that of ægophony, and the voice is distant, but the tremulous, nasal, or bleating characters of the sign are wanting. The modifications expressed by these terms, therefore, depend on conditions not embraced in this experiment. Laennec attributed these modifications to flattening of the larger bronchi by the pressure of liquid, together with movements of the latter caused by the vibration of the lung. If this explanation be not satisfactory, it is certain that none better has been proposed. A bag of liquid interposed between the larynx and the stethoscope, occasions none of the characters of ægophony, and for a good reason, to wit, laryngophony is not bronchophony. The vocal sound from the larynx is characterized by intensity, concussion, and fremitus,

without that elevation of pitch which is essential in order to render it bronchophonic.

Reverting to bronchophony and to increased vocal resonance, while the clinical significance of these important signs admits of no doubt, the mechanism of their production is open for discussion. Laennec considered that an essential element in the mechanism is a better conduction of sound by solidified than by healthy lung. Skoda's experiments prove the reverse of this. If the lungs be removed from the chest, after death from pneumonia, a lobe or more being completely solidified, and an assistant speak through a tube, the end of which is applied first to a solidified and afterward to a healthy lobe, it will be found on auscultation with the binaural stethoscope that the voice is conducted further by the healthy than by the solidified lung.[1] Other experiments referred to in my last lecture also show that lung containing more or less air within the alveoli conducts sound better than either solidified lung or portions of the liver. The same result obtains if the voice of the assistant be directed into the larynx or trachea, and the experimenter auscultate in alternation a healthy and solidified lung. Laennec's explanation of the mechanism is, therefore, not tenable. To meet the difficulty, Skoda resorted to the theory of consonance. The adequateness of this explanation has been sufficiently disproved, and I need not take any time for the discussion of it. Here, then, is an apparent incongruity between an acoustic fact and clinical experience. We must admit that healthy lung conducts sound better than solidified lung. *Per contra*, it cannot be doubted that the thoracic voice, in cases of disease, is often louder over solidified than over healthy lung. Observations during life conjoined with examinations after death prove this incontestably. Which, then, is to give way, the acoustic fact or clinical experience? I answer, neither the one nor the other is to give way. The incongruity is, if possible, to be removed. The acoustic fact is not, for an instant, to be considered as invalidating the significance of the signs. Their significance rests on clinical and autopsical data which are not to be put aside in consequence of any apparent antagonism by physical facts. It is certain that such an antagonism must be only apparent, not real, and the object of inquiry should be to reconcile the apparently antagonistic facts with the truths of clinical experience.

It is to be considered that we cannot artificially combine all the physical conditions involved in the thoracic voice of either disease or health, nor even by means of the lungs removed from the body. The difficulties connected with artificial respiration are such that this method of experimentation is entirely out of the question; but something can be done toward a reproduction of the vocal signs by transmitting the voice through the larynx or trachea into the lungs after death. The contrast in the degree of conduction when the voice is transmitted through the trachea or a primary bronchus into a solidified lobe, with the transmission when the end of the speaking tube is placed upon the surface of the same lobe, proves that in the former instance the sound is conducted, not exclusively by the lung substance, but by air within the pulmonary bronchi. The agency of air within the bronchi is also demonstrated by the following simple experiment: Insert the end of the speaking tube into the trachea, the lungs remaining attached, removed from the body and artificially inflated. The lungs of the calf or sheep will answer as well as those from the human subject. An assistant speaks into the tube, and the vocal resonance over the lung is obtained by means of the binaural stethoscope. Now, introduce a plug of cotton-wadding into the trachea, and compare the vocal resonance with that produced when the trachea is not thus obstructed. The intensity of the resonance is diminished, at least one-half, by plugging the trachea. The question, therefore, as to solidified or healthy lung being a better conductor of sound, has really not very much to do with the explanation of the well-established clinical truth that when the lung is solidified, often but not invariably, the thoracic voice is abnormally intensified. The explanation of this fact has more to do with the air contained within the bronchial tubes than with the solidification of lung. It is easy to account for the transmission of voice sounds from the larynx or trachea, as well as of the laryngeal and tracheal respiratory sounds, if we assume that a column of air extends into the bronchi within the lungs. We have only to instance the stethoscope and the speaking tubes in our houses, for familiar illustrations of the conduction of the voice by the medium of air contained in tubes.

The distinctive characters of bronchophony can be reproduced after death over solidified lung by speaking into the trachea. The voice, transmitted through a solidified lobe, the binaural stethoscope being applied to the lobe, is raised in pitch and near the ear, whereas it is diffused and comparatively distant when transmitted through a healthy lobe. An effect of solidification is thus to modify the vocal resonance as in life. I do not attempt to give an explanation of the manner in which these modifications are produced. The intensity of the thoracic voice, transmitted after death through a solidified lobe, is not increased; but increased intensity, as has been seen, is not to be considered an essential element of bronchophony. The bronchophonic voice may, or may not, be louder than the normal vocal resonance. But we have to inquire, why is it that bronchophony is ever more intense than the normal thoracic voice, and how is to be explained an abnormal increase of vocal resonance without the bronchophonic modifications whenever this is a sign of partial solidification of lung? The *rationale* must have to do with the air contained within the bronchial tubes. I submit the following explanation: Suppose a case of pneumonia in the second stage, one lobe, at least, being completely solidified. The solidified lobe is enlarged in volume nearly or quite to the limit of the expansion at the end of the inspiratory act. Its volume does not diminish with expiration, but remains the same in the inspiratory and the expiratory act. The respiratory movements on the affected side are more or less restricted. Now, the voice is produced by the breath in the act of expiration, that is, it is produced when the current of air is passing from the bronchial tubes of the healthy lung, in consequence of the diminution of the volume of this lung by the contraction of the thoracic space. It seems fair to assume that, under these circumstances, the bronchial tubes on the affected side contain more air than on the healthy side, and that there is less of a current of air in the expiratory act toward the trachea and larynx. Do not these points of difference account for a better conduction of the voice by air within the bronchial tubes on the affected side?

The following experiment has some bearing on this question: A hospital patient under my observation, died with acute pneumonia, the physical signs during life showing solidification of the entire left lung. In order to compare the transmission of the voice before and after the removal of the contents of the chest, the larynx was exposed and within it the end of the speaking tube inserted, the chest walls remaining intact. Blowing into the tube with the bellows and with the mouth produced over the upper solidified lobe a high-pitched tubular sound, and over the right upper lobe a

[1] Holden's resonator makes an excellent speaking tube in these experiments.

vesicular murmur. Moist bronchial râles were heard on both sides, but their presence did not drown the tubular and the vesicular sounds. Speaking through the tube and auscultating with the binaural stethoscope, well-marked bronchophony was heard at the upper part of the chest on the left side, over the solidified lung, and on the healthy side, in the same situation, a resonance corresponding to the normal. The bronchophony, although well marked, was much less intense than during life. Exposing now the lungs, by removing the sternum, and applying the stethoscope upon the upper solidified lobe, bronchophony was still heard, but notably less marked than before the chest was opened. I infer from this comparison that the bronchi within the solidified lung when *in situ*, the chest unopened, contained more air than when exposed directly to atmospheric pressure. But in this experiment only one of the physical conditions underlying the thoracic voice in life is represented. The production of the voice with the current of air in expiration, and the thoracic respiratory movements are, of course, not included.

Granting that the explanation which has been given of an increased intensity of vocal resonance over solidified lobe or lobes in cases of pneumonia be satisfactory, it remains to endeavor to explain an increased intensity of the thoracic voice when the solidification is not sufficient to give rise to bronchophony; when, for example, in cases of phthisis, the increased resonance of the voice represents a greater or less number of tuberculous nodules. Here it cannot be said, in explanation, that the lung remains permanently expanded, nor that the movements of the chest are notably restricted. The bronchial tubes in the vicinity of the nodules may be dilated, but I am not prepared to state that this is the rule. It is intelligible that these tubes may be prevented from collapsing by the proximity of solidified nodules. These physical conditions, however, seem hardly adequate to explain the sign. It is still more difficult to explain increase of vocal resonance when portions of lung are partially condensed by the pressure of liquid or an extrinsic tumor. There must be physical conditions involved which, as yet, are not understood. But, I repeat, to accept this conclusion is not to throw a shadow of doubt upon the diagnostic value of increased vocal resonance as a sign of solidification of lung, wherever associated with other signs denoting that condition.

The increase of vocal resonance over cavities is sufficiently intelligible. If a cavity be superficially seated; if it be not surrounded with lung completely or considerably solidified; if it be empty, and there be free communications with unobstructed bronchial tubes, we have a combination of physical conditions favoring the conduction of the voice, so as to give rise to more or less intensity of resonance, with fremitus, but without the modifications of bronchophony. In a lung removed from the body, this combination of physical conditions existing, notable intensity of vocal resonance, as distinct from bronchophony, may be produced by transmitting the voice into the trachea.

It did not occur to Laennec to study the thoracic sounds produced by the whispered voice. Many years ago, impressed with their value, I was led to institute a series of signs derived from this source. The sounds thus produced have, of course, characters corresponding to those belonging to the expiratory act in respiration; but they are brought out in stronger relief, and are better observed, in connection with whispered words. As these signs are correlative to those produced by the loud voice, it seemed appropriate to designate them by corresponding names. Whispering pectoriloquy was a term which had already been used. Applying to the sounds in health the name *normal bronchial whisper*, the morbid signs were named as follows: *Increased bronchial whisper*, *bronchophonic whisper*, *cavernous whisper*, *whispering pectoriloquy*, and *amphoric whisper*. The differential characters, following the same order in enumeration, are those of the expiratory sounds in broncho-vesicular respiration, bronchial respiration, cavernous respiration, pectoriloquy with the loud voice, and the amphoric voice. It would be superfluous, and therefore tedious, to enter into further description of these signs, and to consider more fully their significance. I would remark, however, that an abnormal increase of the bronchial whisper has often, in my experience, been of much service as one of the signs of incipient phthisis. But with reference to its significance in the diagnosis of that disease, it is essential to take into account the normal points of disparity between the two sides of the chest at the summit. In the infra-clavicular and in the interscapular regions, the normal whisper on the right side is louder than on the left side, but the pitch is a little higher on the left side. Consequently, if the whisper on the left side be louder than that on the right, or even equally loud, it is abnormal; and if the whisper be higher in pitch on the right side, it is abnormal.

Another practical remark relates to whispering pectoriloquy. Here, as with the loud voice, articulated words may be transmitted through solidified lung as well as through a cavity. Here, too, it is not less easy to determine in any instance whether the transmission be through solidified lung or through a cavity. If the pectoriloquy be associated with the characters of the bronchophonic whisper, it is the sign of solidification; but it is the sign of a cavity when associated with the characters of the cavernous whisper, that is, if it be low in pitch and non-tubular in quality.

CONCLUDING REMARKS.

Mr. President and Members of the Philadelphia County Medical Society: In concluding these lectures, I beg to recall the objects which were stated at the outset. I was desirous of showing that Auscultation and Percussion, divested of theories, speculations, non-essential discussions, and needless refinements, may be so simplified as to be made generally available in medical practice. The number of signs obtained by these two methods of physical exploration need not much exceed thirty. In a considerable proportion the characters of these signs are so plainly distinguished, that even their names suffice for a description and their recognition. I desired to show that in order to secure definiteness and clearness as regards the distinctive characters of different signs, and a ready differentiation of them, they must be studied by means of the analytical method. I cannot too strongly express my sense of the importance of relying upon this method of study for our practical knowledge of the signs obtained by auscultation and percussion. I have submitted, as I hope with becoming modesty, the fruits (if I may venture to use that term) of my own studies in this field of medicine for many years—studies relating to the distinctive character of signs, their significance, the introduction of some new signs, and the names by which they are to be designated.

Not ignoring the interest belonging to inquiries concerning the mechanism of the signs, I have entered in these lectures somewhat into a consideration of them in this aspect. My purpose has been chiefly to show that most of the more important of the signs may be produced out of the body, either by simple artificial means, or by using for this end the lungs, healthy and diseased, from the human subject and from inferior animals. The attention which I have of late given to the experimental illustrations to which I have referred, has led me to appreciate, more than hitherto, their usefulness, not only as explanatory of the mechanism

of signs, but as affording valuable aid in teaching practically auscultation and percussion. The production of signs out of the body in the class-room, before bringing students to the bedside for the actual illustrations, must be of much service in facilitating the acquirement of practical knowledge of their distinctive characters, and I commend this exercise to the consideration of instructors in physical exploration.

I need not remind this audience of the inestimable value of the results of the inspired thought which prompted Laennec to improvise a stethoscope by rolling together a few quires of paper. Have these results, after half a century, reached their termination? Is nothing to be expected in the future, in the way of improved means of auscultation? Does the binaural instrument represent the perfection of stethoscopy? I trow not. When we reflect upon the recent development in practical acoustics, as exemplified by the telephone, the microphone, and the phonograph, may we not expect that some inventive genius will develop similar marvels in auscultation? Long before the time of Laennec, a quaint English writer uttered these *quasi* prophetic words: "Who knows but that one may discover the works performed in the several offices and shops of a man's body by the sounds they make, and thereby discover what instrument or engine is out of order." This prediction has been fulfilled. And now, after the manner of Robert Hook, who wrote in 1705, who knows but that the time may come, and perhaps ere long, when the only use of the stethoscope of to-day will be to illustrate, by contrast, an immense improvement in the means of discovering "the works performed in the several offices and shops of a man's body by the sounds they make?"

Treating, as I have done in these lectures, of auscultation and percussion in a purely didactic fashion, I have had to deal with dry topics, which must have been dull to those who have not felt any special interest in the subject. This was unavoidable. The consciousness of the fact enhances the thanks which, under any circumstance, would be due to those who have honored me with their attendance and attention. And in closing, as at the beginning, let me say that I could not adequately express my sense of the honor involved in the invitation to inaugurate a plan of annual lectures which, as I hope, will hereafter be committed to abler hands.

ORIGINAL ARTICLES.

THE MICROCOCCUS OF GONORRHŒAL PUS—INFECTIVE VIRULENCE NOT DUE TO THE PRESENCE OF THIS PARASITIC MICRO-ORGANISM.

BY GEO. M. STERNBERG, M.D.,
SURGEON, U. S. A.

MODERN scientific research having demonstrated that a number of infectious diseases are due to the presence in the infective material—blood, etc.—and multiplication in the bodies of infected animals, of parasitic micro-organisms, having definite and distinct—*specific*—characters, it is not surprising that many physicians are inclined to make the generalization that all infectious diseases are parasitic, and it must be admitted that there is much to be said in favor of this hypothesis. A proper scientific conservatism, however, requires that the list shall be considerably extended before such a generalization can be considered safe; and it is evident that if a single infectious disease is shown to be independent of all micro-organisms, the generalization will be impossible, and the etiology of each specific disease of this class must be worked out separately.

But such a demonstration cannot rest upon negative evidence, for no one will venture to claim that failure to discover parasitic organisms in animal tissues and fluids is sufficient proof of their non-existence, especially since Koch's discovery of a bacillus in material which had previously been examined by numerous competent microscopists without success, at least so far as the demonstration of this particular organism is concerned.

On the other hand, a positive demonstration that infective virulence is due to something else than a living ferment, as, for example, to a peculiar albuminoid product elaborated in the body of an infected animal, would make the hypothesis of an undiscovered "formed ferment"—living organism—unnecessary and unreasonable; for we do not require two efficient causes to enable us to account for the same phenomenon. But I am not aware that such demonstration has been made in any one of the infectious diseases, and I have no evidence of this kind to offer in the case of gonorrhœa.

The question, then, as to the cause of the virulence of gonorrhœal pus remains exactly where I found it when I commenced the experimental study recorded in the following pages, for my researches show that—

The micrococcus which I have found in a certain number of the pus-cells in every specimen of gonorrhœal pus examined by me is an accidental parasite which has nothing to do with the special virulence of this fluid. And—*A careful search with a first-class objective* (Zeiss' 1–18 in.) *and by the use of staining reagents* (methyl violet and other aniline colors) *has not revealed the presence in this fluid of any other micro-organism than this micrococcus.*

This being the case, it may be thought that there is nothing more to be said. But it has seemed to me that a somewhat extended account of the experiments which have led me to the above-mentioned result may be useful in the present stage of inquiry (*a*) to substantiate the statement made, (*b*) to clear the way for others who may undertake a like investigation, and (*c*) more especially as a contribution to the study of micrococci.

My researches show that differences, morphological and physiological, exist among these lowly plants which make it possible to establish species, having characters quite as well defined as have many plants much higher in the scale.

This is in accordance with the views of Cohn and of Koch, and opposed to those of Billroth, Nägeli, and others, who consider all the bacteria as constituting a single species (Billroth), or at least but a small number of species, each including a variety of forms, designated micrococcus, bacterium, vibrio, etc. (Nägeli), which pass constantly the one into the other, being merely different phases in the life-history of the same plant.

That the life-history of some of the bacteria does include a variety of forms can not be questioned. Thus we have in the case of *bacillus anthracis* short rods, in the blood of an infected animal, which

grow into long filaments, in a culture-fluid, in the interior of which are developed oval spores, which are afterwards set free, and might be mistaken for micrococci, but for the fact that they again develop into rods. The life-history of other species also includes a motile form. But there is nothing in such facts to preclude the idea that a large number of distinct species exist in nature, and a somewhat extended study has convinced me that such is the case. Many of these species have, possibly, been independent of each other, and rivals in the struggle for existence, from the earliest period of the earth's history. But as among higher plants, these lowly organisms are subject to variations as to size, rapidity of development, etc., due to circumstances relating to their environment—abundance and kind of pabulum, temperature, etc.; and we already have ample proof that varieties possessing different physiological characters may be produced by special methods of cultivation—attenuation of virus in anthrax and fowl-cholera (Pasteur). The fact that well-defined species do exist, even among the smallest and simplest of the bacteria, will be enforced in the present paper by contrasting two species of micrococcus, which the writer has had under almost daily observation for many months past, and which have been cultivated side by side, in hermetically sealed flasks,[1] without even seeing one form pass into the other, or either develop into anything else than a micrococcus.

One of these species is the micrococcus of gonorrhœal pus, which turns out to be *Micrococcus ureæ*, Cohn, and which has been shown to be the cause of the alkaline fermentation of urine (Pasteur).

The other is the micrococcus found in human saliva, which has been proved to be a pathogenetic species so far as rabbits are concerned.[2]

In my paper upon a fatal form of septicæmia in the rabbit, published in *Studies from Biological Laboratory Johns Hopkins University*, I devote considerable space to the morphology of the septic micrococcus which is also illustrated by photo-micrographs (heliotype prints); a photo-micrograph of the micrococcus of gonorrhœal pus is also introduced, and at the close of this paper is referred to in the following words.

"Fig. 5 is introduced to show that there are micrococci and *micrococci*. The species (?) here represented was obtained in the first instance from gonorrhœal pus. A little of this pus, obtained from a case of two weeks' duration, showed upon microscopical examination, in a few of the pus corpuscles, an invasion by micrococci, while the majority of the corpuscles, as well as the liquid in which they were suspended, were free from organisms. A culture-tube containing sterilized *bouillon* (from rabbit), was inoculated with a little of this pus, and an abundant development of micrococcus resulted. A second tube was inoculated from the first, and a third from the second. The organism was found in abundance in all of these solutions (kept in a culture-oven at 37° Cent.), unchanged in appearance and unmixed with any other forms of bacteria. One cubic centimetre of the liquid from culture No. 3, was injected under the skin of a small rabbit with an entirely negative result. It is evident, then, that physiologically, this micrococcus differs from the deadly septic micrococcus which we have been studying. . . .

The question will naturally be asked as to the possible relation of this organism to the peculiar virulence of gonorrhœal pus. I have not yet found time to study this question experimentally, but think it quite probable that this organism will be found to be identical with the micrococcus found in pus from other sources, *e. g.*, open wounds, inflamed mucous membranes, etc. Whether this common and widely distributed micrococcus is capable under special conditions of cultivation of developing into various pathogenetic micrococci; whether it is a distinct species from our septic micrococcus, or whether the latter is a pathogenetic variety developed from it, are questions which can only be settled by extended and painstaking experimental investigations."

The questions above suggested, I have since attempted to settle by the experimental method, and the object of the present paper is to place upon record the results of my researches.

These results may be summarized as follows:

(*a*) Microscopical examination of numerous specimens of gonorrhœal pus, from a number of cases, has demonstrated the constant presence of the micrococcus first observed in Baltimore in the summer of 1881.

(*b*) Upon inoculating a sterilized culture-fluid (beef-tea, or rabbit *bouillon*) with a small quantity of gonorrhœal pus at the moment of its escape from the meatus urinarius, and placing this in a culture-oven for a few hours, an abundant development of micrococci takes place.

(*c*) These micrococci present in all cases the same morphological characters, and no other micro-organisms than these make their appearance in a hermetically sealed culture-flask,[1] inoculated as above indicated.

(*d*) These micrococci, introduced beneath the skin of a rabbit, produce no noticeable result.

(*e*) Culture-fluids containing these micrococci introduced into the healthy male urethra do not give rise to specific urethritis, or to any other noticeable result.

(*f*) A culture-fluid containing this micrococcus, upon being added to acid urine recently passed and free from micro-organisms, causes it to undergo the alkaline fermentation.

(*g*) Urine which has spontaneously—that is, without resort to experimental inoculation—undergone alkaline fermentation, contains a micrococcus identical in appearance with that obtained by cultivation from gonorrhœal pus.

The deduction from these facts is evident. It has already been formulated, and is included in the title of the present paper.

[1] The writer's method of conducting culture-experiments is described in vol. ii., No. 2, of Studies from the Biological Laboratory Johns Hopkins University, p. 164.

RECORD OF EXPERIMENTS.

At the outset of the investigation the idea naturally suggested itself that the question as to the possible causal relation of the micrococcus to the infective virulence of the fluid containing it, could best be answered by culture-experiments, carried far enough to exclude everything but the living organism, and by inoculation experiments upon susceptible animals.

The following experiments were therefore made with a view to ascertain whether the animals most easily obtainable for such a purpose were susceptible to the action of the virus.

Experiment No. 1 (May 6th).—Inoculated dog (male) in urethra and in right eye with gonorrhœal pus obtained from urethra of a patient in the post hospital, Fort Point San José. In this and the following experiments the pus was obtained from the urethra of the patient by means of a silver probe having a little cotton twisted about its extremity. This was then introduced into the urethra, conjunctival sac, or vagina of the animal experimented upon, and rotated vigorously to make sure that a portion of the pus was detached.

Result of above experiment entirely negative.

Experiment No. 2 (May 8th).—Inoculated female dog in right eye and vagina from same patient as in preceding experiment.

Result negative.

Experiment No. 3 (July 28th).—Inoculated puppy, two months old, in right eye and in vagina with gonorrhœal pus from a patient in post hospital.

Result negative.

Other experiments were made upon rabbits, but the notes have been mislaid. None of these experiments afforded any encouragement to the idea that the test could be made upon the lower animals, and I accordingly determined to seek an opportunity to make it upon man. My first efforts, by the offer of a bribe, to find a willing subject, were unsuccessful, but fortunately my friend, Prof. Hirschfelder, came to the rescue and offered to introduce my culture-fluids into the urethræ of certain patients in his wards in the San Francisco City and County Hospital. These patients consented to the operation with a full knowledge of the possible results, from a desire to please their doctor, and under the promise of speedy cure and a suitable recompense in case of successful inoculation.

The pus from which the cultures used in these experiments were started was taken from cases in the acute stage of the disease, and which had not been subjected to any local treatment.

Experiment No. 4 (July, 1882).—Made by Dr. Hirschfelder with material furnished by the writer. A culture-fluid, fifteenth, containing the micrococcus of gonorrhœal pus was introduced into the urethræ of three patients in the city and county hospital, upon small wads of cotton which were thoroughly moistened with the fluid and left *in situ* for fifteen minutes.

Case 1, J. D., has been in bed for about nine months; caries of the vertebræ.

Case 2, J. B., colored; syphilitic paralysis.

Case 3, D. M., in bed some time; aneurism of the abdominal aorta.

The result was entirely negative.

Experiment No. 5 (Aug.).—A fresh culture, fourteenth, from another, and recent case, was introduced in the same manner into the urethra of J. D., subject of previous experiment.

Result negative.

The culture-fluid, rabbit *bouillon*, used in the above experiments was neutral. In the following a slightly alkaline culture-fluid was used.

Experiment No. 6 (Aug.).—A fresh culture, thirteenth, was introduced into the urethra of W. B.

Result negative.

As already stated, the injection, in Baltimore, of one cubic centimetre of the third culture from gonorrhœal pus produced no perceptible result. This experiment I have since several times repeated.

Experiment No. 7 (June 10th).—Injected thirty minims of sixth culture from gonorrhœal pus beneath the skin of a small rabbit.

Result negative.

Experiment No. 8 (July 17th).—Injected thirty minims of second culture from gonorrhœal pus into subcutaneous connective tissue of small rabbit.

No result.

Experiment No. 9 (July 26th).—Injected ten minims of *sixth culture from blood of septicæmic rabbit* containing the septic micrococcus (Fig. 6) beneath the skin of the rabbit used in last experiment (No. 8). The animal died at 10 A.M., July 29th, and a microscopical examination made at once demonstrated the presence in the blood, and in the effused serum in subcutaneous connective tissue of the septic micrococcus in great abundance.

Remarks.—This experiment shows very plainly the difference between a pathogenetic micrococcus and one which is harmless. These organisms, although having distinct morphological characters (see Figs. 2 and 6), do not differ greatly in size, and both multiply freely in the culture-fluid used. This fluid, with the contained micrococci, proved to be innocuous in the dose of thirty minims in the one case, while one-third of this amount kills the same animal by reason of the presence of the other micrococcus in a subsequent experiment.

Experiment No. 10 (July 29th).—One drop of gonorrhœal pus from a recent case was introduced beneath the skin of a small rabbit.

Result negative.

This experiment is given for what it is worth. I have not yet had the opportunity to repeat it with a larger quantity of material.

The possibility that the micrococcus from gonorrhœal pus might acquire pathogenetic properties by being cultivated in blood-serum having occurred to me, the following experiment was made.

Experiment No. 11 (September 15th).—Injected ten minims of culture of micrococcus from gonorrhœal pus in blood-serum beneath the skin of a guinea-pig.

Result negative.

Remarks.—A single experiment of this kind has of course but little value, and I have not yet found time to follow up this line of inquiry. The question is however an important one, and well worthy of the attention of experimenters in this line of investigation. Here is a micrococcus which is harmless under ordinary circumstances. May it develop pathogenetic properties as the result of special conditions as to temperature, pabulum, etc., artificially maintained for a length of time, and in the course

of successive generations produce a physiological variety having different vital reactions from those which marked the parent stock?

To test the question as to a possible local pathogenetic action of this micrococcus in an open wound, the following experiment was made.

Experiment No. 12 (August 4th).—An incised wound was made with scissors, removing a fragment of skin, upon each thigh of a half-grown rabbit. The wound upon right thigh was moistened with a culture-fluid (twentieth culture) containing the micrococcus from gonorrhœal pus. The wounds were then dressed with dry tow and a bandage applied. Both healed kindly without any undue inflammation, and no difference was observed between the two.

Remarks.—In the recent work on *Antiseptic Surgery*, by Watson Cheyne, the statement is made that micrococci, which, from his illustrations, may well be the same as these, are often found beneath the dressing in the discharges from wounds treated antiseptically, and that no harm seems to result from the presence of these micro-organisms, all of which shows that there are micrococci and *micrococci*.[1]

Having determined that the micrococcus of gonorrhœal pus does not give to this fluid its specific virulence, and having observed its morphological identity with the micrococcus found in urine undergoing alkaline fermentation (*Micrococcus ureæ*, Cohn), the next question was as to the functional or physiological identity. The following experiments establish this:

Experiment No. 13 (July 26th).—Acid urine, drawn from the bladder with precautions to prevent contamination with micro-organisms located at orifice of the urethra,[2] was inoculated with the eighteenth culture from gonorrhœal pus. The urine, in a hermetically sealed flask, was placed in the culture-oven, and the following day was found to be pervaded with micrococci in pairs (Fig. 2), and to be highly alkaline.

Experiment No. 14 (September 3d).—Urine was passed into a test-tube, sterilized by heat, the first flow being rejected (as this contains micro-organisms washed from the mouth of the urethra, *vide* paper above referred to), and was then divided into three portions in three sterilized tubes.

No. 1 was inoculated with the thirtieth culture from gonorrhœal pus.

No. 2 was inoculated with the ninth culture from urine which had spontaneously "broken drown"—alkaline fermentation—and which contained *Micrococcus ureæ* in abundance.

No. 3 was retained for comparison—*témoin*.

The urine was transparent and acid. The external air was excluded from the test-tubes by covering each one with a bit of sheet rubber tied fast about the neck. The tubes were placed in the culture-oven at 100° Fahrenheit, and the following morning Nos. 1 and 2 were found to be clouded, to be pervaded by the micrococcus, and to have an alkaline reaction. No. 3 remained transparent and acid.

Remarks.—I have made many other experiments of the same kind as those above given, but these will suffice to show (*a*) that the micrococcus of gonorrhœal pus causes urine to undergo alkaline fermentation; and (*b*) that it does this by virtue of its own vital activity, and not as a mere carrier of a chemical ferment present, in the first instance, in the gonorrhœal pus used to inoculate culture No. 1, for this hypothesis would require that such a ferment should be as active when diluted to an incredible degree (thirtieth culture) as when present in an appreciable amount—*e. g.*, in the first culture.

In my method of conducting culture-experiments the amount of material taken from one culture-tube to inoculate the sterilized *bouillon* in a similar tube, for the succeeding culture, is less than the fiftieth part of the contained fluid. The amount of dilution to which the original material, introduced into culture No. 1, was subjected in the above experiment may therefore be estimated by raising 50 to the thirtieth power. It is hardly necessary to introduce the array of figures which would result from this computation in order to convince the reader that the original material is practically excluded, and that only the remote descendants of the living organisms which were present in it are likely to be found in our thirtieth culture.

I may mention here, incidentally, that I have ascertained in the course of my experiments that *Micrococcus ureæ* is not the only organism which has the power of transforming urea into carbonate of ammonium—$CH_4N_2O + 2H_2O = (N.H_4)CO_3$.[1]

(To be continued.)

[1] I have not the work referred to at hand, and consequently cannot give the exact reference, but believe that my memory is not at fault with reference to the statement made.

WHEN IS A PHYSICIAN LEGALLY EXEMPT FROM TESTIFYING TO CONFIDENTIAL COMMUNICATIONS MADE TO HIM BY HIS PATIENT?

BY FRANCIS W. SHAIN, M.D.,
OF PHILADELPHIA.

WHAT is a confidential communication or privileged communication in the eye of the law? It is a communication made *bonâ fide*, upon any subject-matter in which the party communicating has an interest, or in reference to which he has a duty, and as the occasion is an absolute privilege, the only questions are whether the occasion existed, and whether the matter complained of was pertinent to the occasion.

In a degree, the law extends this privilege to the lawyer, clergyman, and physician—but not equally, and this we would like to see remedied.

At common law such privileged communication extends only to the lawyer, and naturally, as the profession constantly brought into relation with the accused; it was conceded on the ground of public policy, because greater mischief would probably result from the requiring or permitting of such testimony than from wholly rejecting it; and further, as a fundamental right for the sole and exclusive protection of the client either in person or property, by whom and through whom the obligation can only be removed. It is made perpetual. Does not end or cease with the completion of any par-

[1] Schutzenberger, Fermentation. D. Appleton & Co., New York, 1879, p. 203.

ticular business, the seal of the law once fixed remains forever; and it is generally comprehensive, as implied in the language of the distinguished jurist, Lord Chancellor Brougham: "If the privilege were confined to communications connected with suits, begun, or intended, or expected, or apprehended, no one could safely adopt such precautions as might eventually render any proceedings successful, or all proceedings superfluous." To the lawyer, therefore, by the common law the privilege is universal.

What is the position of a clergyman in this respect? Is he or is he not exempt from testifying to communications made to him in his professional capacity? This question has been the subject of a warm debate on the ground of conscience and general good to society, in that the guilty conscience may unfold itself, and ask for spiritual advice and guidance, and to seek pardon and relief.

The law of Papal Rome has declared that such communications are privileged, and has gone so far as to punish her priests who reveal them, holding to her unchanging doctrine that the confessions are not made to the priest as a man, but in his professional character as the representative of the Deity. In Scotland, if a prisoner confesses his crimes to a clergyman in order to receive spiritual advice, the clergyman is not required to give such communications in evidence.

The English law encourages a penitent to confess his sins for the purpose of unloading his conscience; the clergyman is only exempt from presenting his penitent to the civil magistracy (that is not to turn State's evidence voluntarily) "under pain of irregularity," but must make a full and perfect statement of the communication or confession so received by him in his professional character, whenever required by the law so to do, as it made no distinction between clergymen and laymen. The citizens of New York, through their legislature, passed a statute which has forever, as far as they are concerned, set this vexed question at rest. It is as follows: "No minister of the gospel, or priest of any denomination whatsoever, shall he allowed to disclose any confessions made to him in his professional character, in the course of discipline enjoined by the rules or practice of such denomination." (2 *Revised Statutes*, page 406, § 72.) The Courts of New York have held to the principles of this statute whenever required or requested so to do. It is a pleasing fact to notice that the same protection has been accorded to penitents and clergymen in the following States: Missouri (*Revised Statute* 1845, c. 186, § 19; Wisconsin (*Revised Statute* 1849, c. 98, § 75); Michigan (*Revised Statute* 1846, c. 102, § 80); and in Iowa (*Code* 1851, art. 2393). In States other than those above mentioned the common law principles prevail.

In regard to the communications between a physician and his patient:

The physician under the common law has no status granting privileged communications, nor can the common law be subject to amendment; relief must therefore be looked for by statute law, granted by the legislatures of the respective States.

In several States such statutes now exist, almost rendering unnecessary an argument to prove the right and propriety of extending the privilege to physicians.

The Legislature of the State of New York comes to the relief of the citizen while living, and to his reputation when dead, by a statute of the following character, viz:

"No person, duly authorized to practise physic or surgery shall be allowed to disclose any information which he may have acquired in attending any patient in a professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon." (*Revised Statutes* New York, vol. ii. page 406, § 73.)

The following named States have likewise passed statutes to the same effect: Missouri, Wisconsin, Michigan, and Iowa; but five States in the United States have conceded this wise privilege.

The Courts of New York have been called on for an interpretation of this statute in the only two ways in which such a statute could by any possibility bar justice.

The first was in the case of Hewett *vs.* Prime (21 Wend., page 79), where the Court held that a consultation as to the means of procuring abortion in another is not privileged by the statute; that if A should apply to a physician for a prescription for B who was pregnant, or as to the use of instruments or drugs on the person of B, such communication is not privileged, and the physician would be obliged to testify to the fact.

The second was in the case of Johnson *vs.* Johnson (14 Wend., page 637), in which the Court held the patient himself may waive this privilege, and the physician could then testify, as the privilege, said the chief-justice, was the patient's and not the physician's. He considered it analogous to an attorney and client in this respect; but no statute touching this question exists in Pennsylvania, and in bringing the subject to the attention of the physicians of this Commonwealth, it may be well to cite some illustrative cases, showing the importance to the citizen that he should be able to state the "whole truth" to his medical adviser without apprehension of self-commitment.

An erring and unfortunate citizen presents himself to his physician with a sore upon his genital organs or elsewhere, obscured by previous treatment; and, by a candid confession of exposure, he aids in the diagnosis of syphilis, and is at once properly treated; to his own great advantage, and to the protection of his wife or others from contamination, and so far restraining the spread of this loathsome and grave disease. Now, if this citizen was familiar with the fact that his medical attendant could be compelled in court to convict him of adultery or any other crime arising from illicit intercourse, he would hesitate to take counsel, to his own destruction and to the detriment of public policy.

Again, a man in attempting a burglary, is met by an excited and outraged opponent who strikes to kill, and receives a blow in the temporal region. There exists really a fracture of the bone and

laceration of the middle meningeal artery. The real condition is obscured by the swelling of the superficial tissues, and the patient knowing he must not commit his story of crime to the physician, and not feeling the gravity of the injury, tells the story of being struck by a snow-ball, or by a fall or some such slight cause; the physician is misled, and hours afterwards the patient dies from hemorrhagic compression of the brain. Had the whole trouble been told to the physician, knowing the provocation and probable force of the blow, his investigation would have been more thorough, he would have kept the patient under observation and been able to give him the hope of a trephining operation. Other cases suggest themselves, but these are sufficient to illustrate how necessary it may be for the patient to tell his story unreservedly and without fear to his medical adviser.

Such is the history of the law of the present day, and we trust its presentation will awaken the medical profession to take such action as may secure the passage of a similar statute in Pennsylvania, and indeed in every State in the Union.

HOSPITAL NOTES.

PENNSYLVANIA HOSPITAL.

(Service of DR. J. M. DA COSTA.)

A CASE OF DIABETES INSIPIDUS TREATED SUCCESSFULLY BY ERGOTIN.

(Reported by FRANK WOODBURY, M.D.)

THE following clinical note is worthy of record, not merely as furnishing an instance of the successful treatment of a disorder which had resisted many remedies during a long course of hospital treatment, but also because of the history of the acute beginning, and the progressively downward tendency of a purely functional (vaso-motor?) disease; unaccompanied, so far as could be ascertained, by organic lesions at any stage of its development. The treatment of diabetes insipidus by ergot is, of course, no longer a novelty; but it is still of interest to add an additional case to those already reported by Dr. Da Costa in THE NEWS (Jan. 7, 1882), where a discussion of the therapeutic method may be found.

Charles L., 28 years of age, born in Ireland, a farm laborer, was admitted August 14, 1882, into the ward under the charge of Dr. Arthur V. Meigs.

An interesting point in his family history which was elicited, was a possible hereditary tendency to renal disorder—his father had died of dropsy about three months before the patient's birth. His own health was usually good; he has served in the British army for three years; and had been in this country for eight years. He had spent the most of his time here in living on a farm, but had never had ague nor an attack of rheumatism. He acknowledged having had gonorrhœa, from which, however, he had entirely recovered; but he positively denied all other venereal infection. He never had received an injury or blow upon the head, nor a severe fall; he was equally positive on this point. In August, 1881, while in his ordinary health, he was working hard upon a farm, where he was exposed to cold and wet. About this time he stated that he had come into the city to buy a summer suit of clothing, which he wore on his return to the country; the clothes were thin, and on his way home the weather changed, and a cold rain commenced to fall, so that he became wet through before he reached there. The next day he felt as if he had taken a severe cold; he was dull and heavy; he had irregular chilly sensations and aching in his bones, which obliged him to remain in the house. Shortly after this, within the week, he noticed that he was passing more water, and that he had to rise several times in the night; he stated, however, that the aggregate quantity passed each day then, though more than normal, was not so great as it was a month later.

The malady continued; he urinated frequently, and was very thirsty all the time. In September, he was so ill that he was sent to the Philadelphia Hospital, where he remained under treatment for two months; then becoming dissatisfied, he left the institution, as he said, "worse than when he went in." He then sought admission into a hospital at Trenton, where for ten months he received medical care, but still he got worse rather than better, and as they had given him up to die, he left there, though very sick at the time and reduced almost to a skeleton. In this miserable condition he was found at the gate of the Pennsylvania Hospital about two weeks after leaving Trenton, and was taken at once into the ward. He was so very weak that, although he was passing eight pints of water *per diem*, it was thought better to give restoratives for a time before attempting to place him upon special treatment for diabetes insipidus. His urine, which was repeatedly examined, had a specific gravity of 1010, it was faintly acid in reaction, almost colorless, and was perfectly free from sugar and albumen. At the time the disorder was at its beginning, in September, 1881, he passed eight pints of urine, and again in January, 1882, he had passed a like quantity, as also he had after entering the ward, but he had never exceeded this to the best of his knowledge. Tincture of chloride of iron, quinine, and nux-vomica, were given in succession for a short time, and with these, aided by a diet of milk and eggs and a small amount of stimulants, he revived considerably. In the course of a week after coming into the ward Dr. Arthur V. Meigs began the administration of ergot, of which twenty minims of the fluid extract were given three times a day. He took this small quantity for more than a month, but as it did not have any apparent effect upon the amount of the urine, it was stopped September 19th. No more ergot was given until October 17th, when the administration of ergotin hypodermically was begun; he at first received daily one injection, and afterwards two, of five grains (dissolved in fifteen minims of a solution of equal parts glycerine and water), therefore much larger doses than before. The effect of this treatment was promptly manifested. Under its use the urine had decreased to four pints by the end of the month; but on the remedy being then suspended for a few days, it increased again to six pints. He had greatly improved by October 30th. He had gained eleven pounds in weight in two weeks, his skin was not dry and harsh, he ate and slept well, and although he had been very thirsty before, he was much less so since he had been under the ergotin treatment. He still felt very weak, and was obliged to remain in bed, but his improvement was very manifest.

At this time the ward passed under the care of Dr. Da Costa, who decided to keep up the treatment, only giving the remedy by the mouth instead of hypodermically. The punctures had not given rise to abscesses, but the spots were tender and painful for a time after each injection.

On November 4th he had passed six pints during the preceding twenty-four hours. Five grains of ergotin, using the same solution, were now directed to be given by the mouth, morning and evening, and the succeed-

ing day the quantity of urine was again reduced to only four and a half pints. On November 6th the ergotin was directed to be given three times a day. The next day he was allowed to get out of bed; but as a result, he was not feeling so well on November 8th, and was passing five pints. As he complained of indigestion he was allowed to have a drachm of the compound tincture of gentian before meals, the ergotine being continued. After this he steadily improved: it was noted on the 13th, that "for the last three days the urine has measured three and a half pints daily." The tincture of cascarilla was now substituted for the gentian, as the later did not agree with his stomach. On the 16th, the man was brought before the class; he was still passing three and a half pints; the ergotine was now increased to four doses daily, his general strength and physical appearance had very greatly improved. On the 19th, the remedy was reduced one-half, and the next day discontinued entirely. The cascarilla was continued for a few days longer, but on the 24th strychnia (gr. $\frac{1}{30}$) was given in its place. The urine now ranged between three and three and a half pints daily, and he only occasionally had to rise at night. On the 21st of November, he took a long walk outside of the hospital, but there was no increase in the amount of the urine in consequence, and he slept better that night. As he was anxious to be discharged, he was detained but a few days longer under observation, and was allowed to go on the 30th, when he was apparently strong and well. While under the ergotin treatment he reported that he gained in six weeks the surprising amount of thirty-two pounds in body weight; he weighed in the middle of October but 126 pounds, when he was discharged he weighed in the same clothing 158 pounds, and appeared in sound, vigorous health. He considered that the treatment had saved his life.

MEDICAL PROGRESS.

THE TREATMENT OF PUERPERAL ECLAMPSIA WITH CHLORAL IN LARGE DOSES.—DR. GEORGE ROCHÉ reports a case of puerperal eclampsia occurring in a woman, aged 21, in the eighth month of pregnancy; the face was œdematous, and the urine loaded with albumen. The patient was first bled, cold compresses applied to the head, inhalations of chloroform and ether administered, and rectal injections of chloral in doses of 60 grains—in all 470 grains of chloral were given in 24 hours. Recovery took place.—*L'Union Méd.*, November 28, 1882.

FORTY INCHES OF BOWEL PASSED PER RECTUM, WITH RECOVERY.—At the meeting of the Baltimore Academy of Medicine, held December 5, 1882, Dr. CHRISTOPHER JOHNSTON exhibited a specimen of forty inches of intestine passed by a lady in Charles County, Maryland, per rectum. The patient was thirty-two years of age, married, and had one child about four years old; her health had always been delicate, and she had been subject to indigestion, constipation, and colic pains. The attack during which the present specimen was passed began with acute epigastric pain, at first supposed to be due to cramp colic. There had been no action from the bowels for six or seven days, and a circumscribed hardness could be easily felt through the abdominal parietes. After three days, stercoraceous vomiting set in, and continued three or four days; it was accompanied by some relief. At the end of the three or four days the sphacelated bowel, together with some of the omentum, was passed, followed by loose operations. Part of the specimen retained its tubular shape, and contained feces; another part passed mixed with feces. The prostration during the attack was very great, and death seemed imminent. She began to improve slowly, and to regain her appetite after the discharge of the bowel, but had still occasional pains in the bowels, especially in connection with her evacuations. Six weeks after the attack she was able to sit up a little, and though still feeble, was cheerful, and expressed herself as feeling very well. The treatment pursued was cathartics, enemata, inflation, anodynes, etc.—*Maryland Medical Journal*, January 1, 1883.

EXTRACTION OF A CATARACT WITHOUT EXCISION OF THE IRIS.—At the meeting of the Société de Chirurgie, held November 22d, M. GALEZOWSKI read a paper in which he urged the advantages of abandoning the incision of the iris in the extraction of cataract. He thinks that iridectomy does not prevent inflammatory accidents, and that it predisposes to secondary cataract. M. Galezowski advises making an ellipsoidal flap, making the incision at the edge of the sclerotic. In forty operations made without iridectomy since the month of July, he has had no ocular phlegmons. Iridectomy is, however, indispensable if the iris falls spontaneously under the knife, if there is posterior synechia, or if the border of the iris has been contused during the operation.—*Gaz. Hebdom.*, Dec. 1, 1882.

DISSEMINATED POLYPI OF COLON.—At the meeting of the London Pathological Society held Dec. 19, 1882, a specimen of diffused polypoid growth of the colon was shown by MR. BOWLBY. The case differed from others of the same kind in the absence of constriction of the intestine. The growths extended from the cæcum to the sigmoid flexure; the polypi had long pedicles, and consisted of fibrous tissue, covered by normal mucous membrane. He also showed a specimen of large polypoid growth of the rectum, removed by operation from a young woman; it was attached to the wall of the rectum, and was extruded from the anus during an effort at defecation; it had given rise to no symptoms. Mr. Bowlby also exhibited a specimen of polypus of the small intestine. The patient was a child, who suddenly experienced severe pain in the abdomen; when admitted into St. Bartholomew's Hospital the vermiform appendix and cæcum protruded as a gangrenous mass from the anus. The child died subsequently of congenital syphilis, and at the post-mortem examination it was found that there was some limited peritonitis of old standing, and a large polypus of the small intestine; the whole of the colon was absent, having apparently sloughed away; about three inches and a half above the anus was a constriction, which appeared to mark the point where the continuity of the gut was re-established.—*British Medical Journal*, December 23, 1882.

TREATMENT OF TYPHOID FEVER WITH CARBOLIZED CAMPHOR.—M. DUJARDIN-BEAUMETZ recommends the treatment of ataxic forms of typhoid fever with carbolized camphor. His mode of administration is by the rectum, in the form of injections, with 1 gramme of camphor to 5 decigrammes of crystallized carbolic acid, dissolved in 30 grammes of alcohol and 170 grammes of water. He claims the constant result of these drugs in low forms of typhoid fever has been a reduction of the fever and the disappearance of the nervous symptoms.—*Bull. Gén. de Thérap.*, November 30, 1882.

EXTIRPATION OF THE SPLEEN.—D. G. ZESAS extirpated the spleen in six rabbits under antiseptic precautions, and all recovered. The autopsies showed that there was in all cases an increase in size of the

liver and lymphatic glands, the increase being proportional to the time elapsing between the operation and the death of the animal. Two examinations of the blood, four and eight weeks after the extirpations, showed that at first the red corpuscles and then the white were diminished in number.—*Centralb. f. die med. Wissen.*, Dec. 2, 1882.

OXYGEN AND DISEASE GERMS.—Mr. F. J. Faraday calls attention in the *Times* to certain remarkable facts communicated by M. Pasteur to the recent Hygienic Congress at Geneva. Starting with the suggestion by Dr. William Roberts, F.R.S., that disease germs might be "spores" from harmless saprophytes which had acquired a parasitic habit, it has been argued that such "spores" might be developed by cultivation in the presence of noxious gases, or in confined places in which the proportion of free oxygen present in good air did not exist. The hypothesis has been specially applied to the evolution of the tubercle bacillus, but it is obvious that it is equally applicable to the evolution of the germs of other diseases, such as typhoid fever. The process described by M. Pasteur at Geneva, as having enabled him to convert the virus of the form of typhoid fever which caused great mortality among horses last year in Paris into its own vaccine, has a noteworthy bearing upon this hypothesis. M. Pasteur first tried to "attenuate" the virus by cultivating the specific microbe, which he had already discovered as associated with the disease, in contact with air. But experiments showed that the culture retained its fatal attributes for a certain period, when it suddenly became absolutely sterile, or, in other words, the microbe died. M. Pasteur then adopted a method which can only be described as a process of nursing the microbe, so as gradually to adapt it to a new mode of life, or, in other words, to modify it without destroying its fertility. Taking a virulent culture from the blood of a rabbit which, through inoculation, had died of the disease, he sowed fresh portions of this culture in veal broth on successive days, and kept the series in contact with air. He had thus a graduated series of cultures from virulent stock in process, each of these cultures having been subjected to the modifying influence of oxygen for a different period. M. Pasteur was thus able to seize the moment when the culture which had been exposed the longest to aeration became sterile, and to select a culture on the eve of sterility, which he transferred to a fresh infusion already found to be specially suitable to the microbes, and which consisted of two parts of veal broth with one part of pure rabbit's blood. Having, in fact, reduced the microbe to the verge of sterility, or death, he subjected it at this critical moment to an invigorating regimen, and thus protracted its vitality and made it the stock of a new series of cultures. By repeating this process again and again in all its details, M. Pasteur ultimately evolved a race capable of serving as the vaccine of the original virus, oxygen having been the modifying influence throughout.

There is a striking analogy between the treatment thus described and that by means of which, about six years ago, Fräulein Marie von Chauvin evolved *amblystoma*, a land salamander, from the water-breathing Mexican axolotl. She selected healthy animals, and first kept them in shallow water, so that they were not quite covered by the water. When their health declined she restored them to deep water. Gradually she accustomed them to shallow water, and eventually kept them on land in deep moss. She was obliged to force them to eat by compelling earth-worms to wriggle down their throats; and feeding them well at the critical stage of metamorphosis seems to have been the main condition of success. When the change from gills to lungs was perfected, they fed themselves with avidity. But Nature herself, notwithstanding the difficulties experienced by Fräulein von Chauvin in transforming her axolotl (some of which died under the treatment), apparently succeeds sometimes in evolving *amblystoma* from the Mexican newt; therefore, assuming the variability of specific microbes under the influence of oxygen, there is nothing unusual in the idea of the parasitic germs of epidemics being spontaneously evolved from harmless saprophytes under peculiar conditions of culture, such as the presence of various gases instead of free oxygen. In that case, ill-ventilated sewers, stagnant pools, and other places where aeration is not efficiently carried on, may continually evolve new crops of specific disease germs. Moreover, no embryologist will object to the attribution of the characteristics of species to the infinitely little, and the resistance to retransformation under artificial conditions displayed by M. Pasteur's typhoid microbe is only what we might expect, on the assumption that it is a confirmed new species. Fräulein von Chauvin's axolotls had to be forced to eat under the new conditions which she provided for them, and they would certainly have died if they had been left to themselves.

The behavior of M. Pasteur's typhoid microbe, which retained its specific or virulent character even under the influence of oxygen, until it suddenly died, is singularly like that of the axolotls. Does it not also explain the often sudden disappearance of epidemics? The typhoid germs, having acquired a parasitic or virulent habit, say in the sewer, are conveyed to the bodies of human beings. Though subsequently exposed even to the abundant oxygen of a healthy locality, they resist its influence for a certain period, spreading death meanwhile, and then, under the influence of sanitary conditions, they suddenly become sterile and the epidemic disappears.—*Knowledge*, October 13, 1882.

EXTIRPATION OF THE SUB-ORBITAL NERVE.—At the meeting of the Société de Chirurgie held Nov. 29, M. POZZI read a memoir by M. BLUM on this subject. A woman, aged 68 years, had for two weeks suffered from severe neuralgia of the left side of the face; all treatment proved unavailing, even the extraction of all the teeth of the upper jaw. M. Blum therefore cut down upon the sub-orbital nerve and tore it out; the pain then ceased, and has not returned. M. Pozzi states that this procedure has only been employed in three instances; one was followed by cure, and the other two were unsuccessful in relieving the pain.—*Gaz. Hebdomadaire*, Dec. 8, 1882.

SUBCUTANEOUS INJECTION OF ETHER IN IMMINENT DEATH FROM HEMORRHAGE.—At a meeting of the French Academy of Medicine, held December 19, 1882, DR. HAYEM read a paper with the above title, of which the following is an abstract. When a dog has been bled to the extent of causing convulsions, and death is imminent, injections of ether are of no service: transfusion of blood may, however, in such cases save the animal's life. The results of the subcutaneous injection of ether are also negative when an amount of blood equal to one-nineteenth the weight of the animal has been withdrawn and the animal brought into a condition where the chances for life or death are about equal. In this state also, life may be assured by transfusion or the injection of serum obtained from blood of an animal of the same species. These results show that transfusion cannot be replaced by the stimulant effects due to subcutaneous injection of ether, which only increases the number and vigor of the heart's pulsations, and does not augment the blood-pressure or rectal temperature.—*L'Union Médicale*, December 21, 1882.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JANUARY 20, 1883.

RESECTION OF THE TARSUS FOR INVETERATE CLUB-FOOT.

ESPECIALLY in the treatment of deformities, osseous surgery, if we may so designate it, has made rapid progress during the last ten years, and operations formerly unthought of, or deemed inadmissible, are now of frequent occurrence.

As a rule, club-foot is amenable to less heroic measures than bony resection, but occasionally cases occur that resist all other modes of treatment, and so long ago as 1853 Little proposed, and in 1854 Solly performed, an excision of the cuboid. Since 1874, however, chiefly owing to the operations of R. Davy and E. Reid, the systematic resection of portions of the tarsus have been undertaken. But while in England and Germany the operation has been known and accepted, in France and in this country but little has been done. Erskine Mason, Stephen Smith, Porter, Bradford, and other American surgeons, however, have done a few operations.

In the *Archives Générales*, we find an excellent aper on these operations by CHAUVEL, of Val-de-Grâce, which well repays perusal. Three different methods exist. In the first or "anterior," the cuboid only is removed; in the second or "posterior," chiefly or wholly the astragalus, and in the third, or "total cuneiform resections," a wedge-shaped piece is removed, involving chiefly the cuboid and its neighboring bones, but extending, if need be, even to the inner border of the foot, though in ankylosis Reid has applied it to the ankle proper.

The first operation has been done, according to the statistics of Chauvel, eight times on six patients. Recovery has followed in all cases. The immediate results have been good, but the ultimate results were satisfactory in only one-half of the cases.

The second operation was done thirteen times; six of these were resections of the astragalus and bones of the leg in wedge-shaped pieces, followed by six successful ankyloses; seven were resections of the astragalus, either alone or combined with removal of the external malleolus, followed by two definite successes, four cases in doubt, and one bad result.

The third method was practised thirty-seven times. Three deaths resulted, one on the tenth day from an old cardiac valvular insufficiency with recent endocarditis, one from hospital gangrene, and the third from septicæmia. The operation should be held responsible only in part for the first two. Of the ultimate results in the thirty-four cases that recovered, in twenty-four it was satisfactory, and in ten undetermined, some of which certainly would have been counted among the successes.

The deformities to which the operations are applicable are otherwise incurable varus, equino-varus, and equinus. In varus and equino-varus undoubtedly the total cunieform resection is the best operation, and has been oftenest done. Removal of the cuboid only has deservedly met with but little favor. If the case be one of pure varus, the wedge has its base at the cuboid, the width of the base and the length of the wedge being proportioned to the degree of the deformity to be corrected, and without special regard to the articular surfaces of the cuboid or other bones involved. Indeed it is less important that exactly this or that bone be removed than that the wedge be well placed, and of proper size. Not seldom indeed more than one subsequent slice has to be taken off the bone, in order to obtain good apposition of the bony surfaces. In equino-varus the excised portion must be wedge-shaped in two ways—(*a*) the base as before at the cuboid externally, and apex internally to correct the varus, and (*b*) the base above and apex towards the sole to correct the equinus. In equinus proper, the anterior operation or resection of the cuboid, and the total cuneiform method will not remedy the deformity so well as the posterior operation at the ankle-joint. This should consist not so much in the removal of the astragalus or of the astragalus and external malleolus, as of a wedge-shaped piece or pieces involving both the upper and lower articular surfaces of the ankle of such size and shape as to correct the deformity, or a wedge-shaped piece may be removed just in front of the joint involving the head and neck of the astragalus, and the calcaneum if necessary.

So far as possible these operations should be subperiosteal and antiseptic. Because they are deliberate and designed, they are none the less severe

compound fractures, involving also, in most cases, the neighboring articulations, and in the part of the body most distant from the centres of nutrition. Hence, every possible precaution must be taken to insure the least risk and the quickest healing. This at best, if we obtain bony union, must be slow, and cover some weeks or even months.

The operative procedure is simple. The incisions in ⌊ or ⊥ at suitable places and of suitable length give easy access to the bones. The saw may be used, but the chisel and bone-forceps are preferable, and in children a stout cartilage knife will often suffice. The arteries are well known and avoidable, and serious hemorrhage is rare. The dorsal tendons and, also, especially that of the peroneus longus should be carefully preserved. Tenotomy will be required occasionally, either at the time of the operation or subsequently. Antiseptic dressings and a suitable splint, with a foot-piece, are to be immediately applied. The splint in some form or other, according to the preference of the particular surgeon, is indispensable in order to retain the foot in its proper position.

If the results have been so good in these the earlier operations, we have every reason to believe that still better are in store for us within the next decade. American surgeons certainly should not be behind in working out so favorable a result.

BACILLUS LEPRÆ.

AMONG the infectious diseases which have recently been ascribed to a micro-organism is leprosy. A close examination of the studies which have from time to time been made upon the *bacillus lepræ* show a better foundation for such a view than would at first be expected, though the same examination will also show that the evidence in its favor is much weaker than in the case of the *bacillus malariæ*.

The first observations on this subject appear to have been made in 1873, by Dr. G. A. Hansen, of Bergen, Norway, and published in *Norsk. Mag. f. Lægevidensk*, 1874, and more fully in *Virchow's Archiv* for January, 1880. He found constantly in the nodules of leprosy, both rod-shaped and granular bacteria, enclosed in certain brown-colored cells.

Dr. Albert Neisser, then of Breslau, now of Leipzig, extended these observations of Hansen's in a study of leprosy pursued in Granada in the winter of 1880–81, employing, for the first time, the staining methods of Weigert and Koch. Neisser claims to have been the first to declare that there exists in leprosy a specific form of bacteria which is the direct *cause* of the disease, while Hansen had originally merely suggested that such relation might exist. Neisser also made a culture of the bacillus.

In May, 1881, Dr. I. Bermann, of Baltimore, succeeded in demonstrating the bacillus lepræ in the "lepra cells" in sections of skin removed from a leprous patient. Recently (Dec., 1882) Hansen has published another paper in *Virchow's Archiv*, confirming and extending his original results by culture experiments. The names of Klebs and Ecklund have also been associated with studies on *bacillus lepræ*.

The *bacillus lepræ* is a peculiar one, being very attenuated and further characterized by black dot-like nodosities, sometimes at one end, at others at both, while sometimes there are found two or three intermediate dots, in which event the bacillus is always longer. These granules have probably something to do with spore formation, and may entirely replace the bacilli, which then appear to break up into them.

As to their occurrence, the bacilli, at least in the tuberculous form of leprosy, are found wherever the leprous productions occur, be they recent or old. This is especially true in the nodules of the external integument. Hansen has never seen the involvement of the liver, spleen, testicle, lymphatic glands, and nerves in its early stage; but when he has found these organs diseased, the bacilli were present in them. Nor has he ever seen the latter in the blood, though Köbner claims to have found them there in his patient. Nor did Hansen find the bacilli in the anæsthetic form of the disease, although his opportunities for the study of these have been limited.

An important link in the argument is, however, wanting, in that none of the attempts at inoculating leprosy in the lower animals, either by the introduction of pieces of leprous tissue or by the injection of the culture fluid swarming with bacilli, have been successful. It is true, Neisser claims to have communicated leprosy to dogs by inoculation, but both Köbner and Hansen, who acknowledge to have themselves failed to inoculate monkeys, consider Neisser's results doubtful and unsatisfactory. Of course, until more uniform success results from inoculation experiments similar to those which have followed the inoculation of *bacillus malariæ*, the existence of a specific bacillus cannot be admitted. In the above, however, we present our readers with what may be considered the present state of the question.

CHILDREN'S FOOD.

WE remember once going to see a respectable mechanic's child who had just recovered from an attack of cholera morbus. We found the boy of three years sitting at the tea table wrestling, and successfully, too, with a dozen fried oysters, a good-sized bowl of pretty strong tea, and a mug of beer. Thanks to our subsequent, but, we also regret to add, our unrequited, skill, he escaped the dangers

of a relapse, to fall a victim a year later to similar parental indulgence. Such an incident, together with many another drawn from late Christmas experience, may well point a moral as to the food of children.

Up to two years of age, little besides milk should be given. Before this age the stomach cannot bear stronger food. Even after it, and up to adolescence, great care is required in the choice of the diet. It should be simple in *quality*. Milk, oysters, eggs, plain farinaceous foods, easily digested and simply cooked meats, these should constitute the staple. Even if the children eat at the family table—an American habit we most heartily commend, because of its happy influences on both parents and children—they should be restricted to the simpler foods. Indeed, it is to be hoped that the very difficulty of enforcing such restrictions may lead to the abandonment of the richer dishes rather than to the exclusion of the children.

But it is especially the villanous but delightful concoctions at dessert that we must condemn. Pies and doughnuts are bad enough, but the wonderful combinations in various "sweets," to tempt an already satisfied appetite, are well-nigh a dietetic Pandora's box to all—except the doctor. Like St. John's little book, they are sweet in the mouth, but bitter in the belly. Children should never touch them any more than the rich ragouts or the highly spiced dishes of the rest of the meal. Fruit, ripe and wholesome fruit, varied so happily in this country from month to month, should be the usual dessert, with occasionally simple puddings and the plainer cakes. The hot biscuits and various forms of breakfast cakes we would not austerely exclude the whole year round from the older children, but let them be enjoyed as rarities.

The *quantity* of food eaten is not nearly so important as its quality. Children in good health will not often overeat if the food be simple. It is the enticing superfluities that do the mischief. Fear not only "gift-bearing Greeks," but gift-bearing cooks as well. If the appetite flag, and too little food be eaten, a little beef tea, tid-bits, and varieties may be used, which need not be unwholesome because uncommon; for a time a little stimulant may do good.

Many children, like many horses, thrive well on but little food. Personal idiosyncrasies must be taken into account. The scales are the best test. So long as a child gains in weight, even only slightly, parents need not, as a rule, have any anxiety.

The *regularity* of children's diet is also of prime importance. The stomach needs its periods of rest as much as the brain or the muscles. Feeding between meals, even if the food be wholesome, is noxious; not but that occasionally some good bread and butter, or a little fruit may be proper for a growing, romping child, but the rule should be the other way. To give candy, doughnuts, cakes, pie, etc., between meals, is unintentional cruelty. It not only cheats the stomach of its needed period of rest, but destroys the appetite for the succeeding meal. Candy in moderation, and as a dessert, may be allowed as a venial sin—certainly a winsome one. But it should be well chosen, and bought only of reliable dealers. Not a little arsenic or other poison sometimes lurks there.

When we say "between meals" we do not mean that the meals shall only be three in the day. Growing children need at least one lunch, especially if the interval between breakfast and dinner be a long one. Very often children in private schools do not get dinner until two or three o'clock. Six or seven hours between meals is too long an interval without food, and every child so situated should be supplied with a hearty lunch at recess.

The general tenor of the above remarks applies equally to children's *drinks*. Milk or water may always be given. In winter, when something hot at breakfast is desirable, chocolate and its allies may be used with advantage. Tea and coffee should never be given to young children, and only in moderation, if at all, before twenty years of age, except occasionally in cases of sickness. Among the poor especially, as our opening story shows, the vicious habit of giving tea in large quantities to young children is common, and it cannot be too strongly condemned. Beer, wine, and all the stronger forms of stimulants are, *ipso facto*, the more to be condemned. Apart from the moral dangers they are harmful physically. The parent who gives them commits well-nigh a crime.

EXPERT UNEXPERTNESS.

IN a recent issue of one of the journals devoted to specialties in medicine, we find a case recorded under the title of "post-scarlatinal insanity," in which the author expresses himself as having experienced serious doubts whether the case should be regarded as post-epileptic or post-scarlatinal insanity. Our readers who are not neurological experts, but who do know something of general medicine, would not be surprised to encounter a case of convulsions in a girl of nine years, during the desquamative period of scarlatina, or that a joint affection had supervened in the same case. But by an expert these ordinary complications are narrated with an impressive gravity befitting an account of unprecedented phenomena. The forms assumed by the delirium are described with a pompous formality of sounding epithets. Thus, the girl of nine "manifested rudimentary delusions of

grandeur strongly tinged with imbecility." In another place, "there is evident amnesic aphasia with word deafness," because, forsooth, "in answer to questions she invariably responds 'flees.'"

We learn further that "to anticipate several questions which are sometimes asked, I will say that no sphygmographic, electrical, or craniometrical examinations were made." Our readers will surely regard our statement as incredible when we say that the account contains not one word of the state of the urine. Notwithstanding the fanfaronade of technical phrases, there is not a word in respect to the condition of uræmia, which was, doubtless, the true explanation of the convulsions and of the delirium. Surely it does not require an extraordinary expertness to diagnosticate the uræmic complications of scarlatina, but it would appear that the psychiatric expert can find no organ diseased except the one with which he is concerned, and that all others are of little importance in causing any form of symptomatic disturbance.

A GRIEVANCE OF PASSED ASSISTANT SURGEONS IN THE NAVY.

MANY passed assistant surgeons now in the navy have been recently deprived of their seniority, fairly assigned them after competitive examination in accordance with a custom prevalent since 1824, which is recognized in legislative Acts of 1828 and 1835, through a literal construction by the Attorney-General, on February 25, 1881, of a law of March 3, 1871, as epitomized and presented in the Revised Statutes of the United States in 1877.

In order that they may have restored to them the seniority in their class of which they have been thus unjustly, though legally, deprived, they have petitioned Congress to enact, "That Passed Assistant Surgeons in the Navy shall be arranged upon the Navy Register according to merit, as determined by the system of competitive examination which has heretofore prevailed; and that this Act shall apply to the Passed Assistant Surgeons now borne upon the Navy Register, and all future assignments to positions on said Register shall be made pursuant to such competitive examination."

The appointment and promotion of assistant surgeons in the navy in accordance with the results of competitive examinations have had, it is universally admitted, the effect of procuring for the naval service better qualified practitioners than it could have obtained otherwise. This competitive examination presents the strong motive of personal interest to induce the competitors to strive zealously to obtain seniority by increasing their professional acquirements, because the higher the seniority the earlier is the promotion to the grade of surgeon. The measure asked for is surely proper, and it is therefore hoped that it will be speedily granted.

THE GARFIELD BOARD OF AUDIT.

THE award of $20,500 to the four surgeons summoned to attend President Garfield has been received by them. In response to the question of a newspaper interviewer, Dr. Hamilton is reported to have said that he accepted his cheque in much the same spirit as he would a dividend from a bankrupt corporation.

We are informed that the report of the Board of Audit has been called for in the House. This will again bring up the whole subject, and, in reaching a conclusion, Congress will have the aid of the light thrown upon the value of professional services as shown by the sums recently paid, without demur, by the Government to the lawyers in the Guiteau and Star Route trials. Congress will then also have it in its power to do tardy justice to the surgeons who are compelled to accept whatever may be awarded them, since, generously confiding in the justice of the Nation, they, by request, signed away all claim upon the estate of President Garfield, as a prerequisite to the case being brought before Congress for settlement.

Members of Congress, who are for the most part lawyers, have shown, perhaps not unnaturally, a willingness to make liberal compensation for legal services rendered to the Government, and we hope that they will now embrace this last opportunity to make, at least, a just remuneration to the eminent surgeons whose professional services were unsparingly given to our late President, under particularly trying circumstances.

THE new contribution to cardiac therapeutics, *Convallaria maialis*, has been carefully studied by Dr. Desplats, and his results are given in a special memoir. He concludes that convallaria is practically useless in ascites due to cirrhosis, and is of doubtful utility in albuminuria, and in cardiac icterus (nutmeg liver).

In cases of obstruction or regurgitation at the mitral orifice, with visceral congestions, dropsy, etc., convallaria lessens the number and improves the strength of the cardiac contractions, increases the urinary discharge, and thus removes the congestions and dropsy. It is, therefore, distinctly useful in this group of diseases. In his treatise on the diagnosis and treatment of heart diseases, Prof. G. Sée reaffirms his original opinion in regard to the utility of convallaria, which was strongly expressed in favor of its use in the group of cases for which it is advised by Dr. Desplats. Sée regards it as superior to digitalis in cardiac dyspnœa, in which he combines it with the iodides.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, December 26, 1882.

THE PRESIDENT, T. M. MARKOE, M.D., IN THE CHAIR.

EXCISION OF THE ARTICULAR EXTREMITIES OF THE PHALANGES.

DR. POST presented a patient upon whom he had operated for the relief of an angular deformity, of about fifty degrees, of the index finger of the left hand. It was one of a class of cases in which he had operated a considerable number of times within the past few years, by excising the end of the phalanx. About fourteen years ago this patient had his finger dislocated while playing base-ball. The dislocation was not reduced, and the terminal phalanx remained flexed at about the angle mentioned. For some time before he came under Dr. Post's observation there had been suppurative disease, and on examination there were found two sinuses leading down to rough bone. The operation, therefore, was performed not merely for the correction of the deformity, but for the removal of the carious portion of bone, and in this instance instead of excising the distal end of the proximal bone, he excised the diseased portion of the ungual phalanx. The operation had been performed a little more than three weeks, during which time the finger had been supported by a splint. Three days ago the splint was removed, and the parts were supported by adhesive plaster. The wound healed readily, and the deformity had been corrected. Dr. Post said that the operation in his experience had not been attended by so much irritation as had amputation of the phalanx. He had applied the same operation to the phalanges of the toes. He had not met with a case in which there had been any considerable amount of irritation following the operation. He believed that the wounds healed quite as readily as after amputation. He had not succeeded, of course, in securing a perfect joint, although there had been in nearly all the cases some motion. The after-treatment consisted in keeping the parts supported until they became sufficiently firm to sustain themselves.

The PRESIDENT then read a paper on

TRIPIER'S MEDIO-TARSAL AMPUTATION.

During my residence at the New York Hospital, in the years 1839, '40, '41, one of our best surgical nurses, a man named George Compton, had lost both of his feet by amputation through the tarsus by Chopart's method. He wore on each foot a shoe, not very ingeniously contrived, nor very neatly constructed, but one which, nevertheless, by much forbearance and not a little suffering, he was able to wear occasionally, and to stump about his ward with considerable agility, which certainly was the reverse of graceful. I remember that he used to pad his shoes very carefully with layers of old blankets, cut to fit the stump, and then lace them very tightly around the ankle and part way up the leg. Thus provided, he was able to get about with some comfort for a certain time, but soon the pressure upon the cicatrices gave rise to pain and soreness, frequently terminating in most intractable ulceration, and it must be acknowledged that, brave as he appeared in his shoe toggery on Sunday mornings, as he walked down the front avenue leading to Broadway, he would commonly come back in the evening wearied and limping, and glad enough to get rid of his uncomfortable shoes, and only too happy to be allowed to stump about on his knees. Of course, he was not at all times equally disabled. Several of the surgeons of the hospital tried to improve his stumps by various operations and modes of treatment, but without any permanent benefit, and to the last his active and useful life was rendered miserable by the constant irritation of ulcerated and tender stumps, and his intelligence and courage and endurance only showed what a prize he might have won in life's race if he had not been so heavily handicapped. I did not then study the position and relation of the bones, as I should be only too happy to do now; but this I remember, that his chief trouble arose from the frequent and intractable ulcerations of the face of the stump, showing that the cicatrix bore the chief weight of the body when he walked, and was, therefore, constantly suffering from the effect of pressure directed immediately upon it.

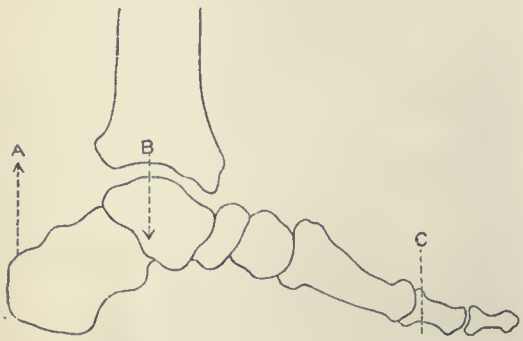
This unfavorable behavior of the stump left by Chopart's amputation has been noticed by all the surgeons who have had much to do with this operation, and much thought and ingenuity have been expended in endeavoring to explain and to obviate it. In regard to the cause, all seem to be agreed that it depends upon a change in the position of the stump whereby the heel being forcibly drawn up, the front part, or the cicatricial face, is thrown downwards, so that, instead of resting on the natural plantar cushion of the inferior surface of the stump, this anterior face receives the whole weight of the body. It is somewhat remarkable that so wide a diversity of opinion should exist among really good observers as to the reason of this change. It would seem to be a simple and adequate explanation of the deformity to say that it is due to the unopposed contraction of the gastrocnemial muscles, but I find that, at a recent meeting of the Société de Chirurgie in Paris, a M. Larger read a paper on the causes of the tilting of the heel after partial amputations of the foot, and arrives at the conclusion that it is due solely to the atrophy of the anterior muscles of the leg, and not at all to the action of the calf muscles, which, he asserts, take no active part in the change of the position of the heel. Acting upon this theory, he applies electricity to the weakened muscles, and insists that any other treatment is entirely unphilosophical, and therefore useless. The report of the committee to whom this paper of M. Larger was referred, did not accept the exclusive views of the writer, and while they acknowledged the possible occurrence of the atrophy in question, they felt that they could not ignore the powerful influence of the muscles of the calf. In the course of the discussion which followed, M. Vernenil contended that both the anterior and the posterior muscles of the leg undergo atrophy after these amputations, and that therefore neither of them have anything to do with the displacements in question.

By all the older, and by far the larger number of the best modern authorities, the calf muscles are fully recognized as the active agents in producing, or at least in perpetuating, the deformity. The main practical question, it seems to me, is what other vital or mechanical conditions favor, though they may not originate, the undesirable position which the fact is so apt to assume. That there are other causes which at least contribute to this undesirable result would seem to be proved by the fact that division of the tendon has been recommended by many of the best operators, and yet it is universally acknowledged that this procedure does not by any means always prevent the deformity, and still less cure it when it has occurred. Let us look now at one of these accessory causes, to my mind a very important one, and see what practical relations it may have to the main cause, and to the prevention of the trouble.

While the patient is in a standing posture, the tendency of strong contraction of the gastrocnemial muscles

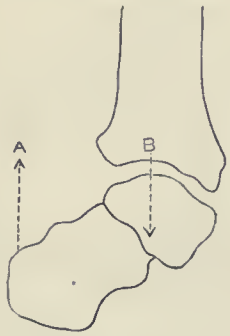
is to draw up the heel, and thereby extend the foot upon the leg. This movement is resisted by the long lever of the foot pressing upon the ground, and thereby preventing the extension from taking place. The only effect then of moderate action of the sural muscles is to keep the foot firmly planted on the ground, and at the same time to prevent the body from falling forwards. If now the action of the calf muscles be much increased, the ball of the foot remaining in contact with the ground, the effect will be to raise the posterior part of the foot, and with it the whole body, which rises as the act of extension of the foot on the leg is accomplished. The action results from the power A acting on the short arm of the lever moving the resistance B on the fulcrum C, which is at the end of the long arm of the lever (Fig. 1).

FIG. 1.



Now let us suppose, as happens in Chopart's amputation, that the long arm of the lever is removed by section between the scaphoid and astragalus; and then we should have the power A unopposed by the fulcrum C, and therefore unable to counteract the resistance B, which would force the astragalus downward until it came in contact with the ground. This becomes plain by glancing at Fig. 2.

FIG. 2.



If now the unopposed power A continues to act, its only further effect, after the astragalus has reached the ground, must be to raise higher the heel and thereby roll the astragalus in its mortise between the malleoli, so that its anterior face looks more and more downward, until finally it comes to press directly on the ground. It must not be forgotten, however, in thus estimating the action of the sural muscles, that if their influence should be entirely eliminated (as by tenotomy, for example) there would still remain in the obliquity of the under surface of the bones remaining after a Chopart's amputation a mechanical reason why the heel should rise and the astragalus descend as soon as the weight of the body is brought to bear, as in the act of standing. These two causes, then, it seems to me, conspire to produce the result we are considering, viz., 1st, the unopposed contraction of the gastrocnemial muscles; and, 2d, the oblique surface, in reference to the level of the ground, presented by the inferior surface of the bones which constitute the stump. When now we add to these statements the fact that the ligamentous tissues around the ankle-joint soon become so contracted and so rigid in their changed position that, even when the tendons are cut, they will obstinately maintain the displacement, we have related the chief, if not the only, causes which produce or perpetuate the deformity now under consideration. A review of these different causes shows also why it is that the deformity is not in every case relievable by section of the tendo Achillis; and particularly why that operation, performed after the lark heel has become established, does in many cases so little to improve the usefulness of the medio-tarsal stump.

The study of the causes of the deformity of the Chopart stump has led surgeons to seek some plan by which it might be avoided, and various suggestions have been offered in that direction. The one to which I wish to call the attention of the Society is one which was first brought forward by M. Tripier, of Lyons, and which has since gone by his name. It may be considered as a modification of Chopart's amputation in so far that the astragalus and calcaneum are left; but it differs from it in this, that a segment is sawed off from the lower part of the os calcis in such a way as to leave the lower or plantar surface of the bone showing a line parallel with the surface of the ground on which it bears in standing or walking. This section is made at the level of the sustentaculum tali in such a direction as to bring the line of the saw-cut at right angles to that of the tibia, leaving therefore a bone surface which, when the weight of the body is brought to bear on the stump, will have no tendency to change its relation parallel to the ground on which it rests. This is the principle of the operation, and its originator claims for it a great success. The cases in which the operation has been tested, thus far, are very few in number, and time enough has not yet elapsed to enable us to reach a final verdict as to its merits. In the *British Medical Journal*, of February 26, 1881, Dr. P. J. Hayes, of Kingston, Surgeon of the Mater Misericordiæ Hospital, reports a case in which he operated by this method, the man making a good recovery, and walking without a crutch in a month. He has since repeated the operation with a like satisfactory result. Mr. Wagstaffe, in the *London Medical Record*, discusses the merits of this operation and approves of it as likely to prevent the tilting heel. He contrasts the operation with the sub-astragalar, and gives preference to the method of Tripier. He does not say that he has ever done the operation.

Tripier's amputation is performed by an incision which commences on the outer border of the tendo Achillis, on a level with the outer malleolus, passes downward and forward, skirting the malléolus about one inch below it, passes then along the outer border of the foot, rather more toward the dorsal than the plantar surface, till it reaches the base of the metatarsal bone of the little toe. The line of incision here turns upward and inward, passing across the dorsum of the foot till it reaches the base of the metatarsal bone of the great toe, and then turning downward and forward into the sole is continued across the sole, making a convex flap at least an inch longer than the dorsal. When it reaches the outer border of the sole, it turns backward and upward, and joins the original incision at an oblique angle on the outer side of the foot. The flaps thus marked out are raised so far as may be necessary to disarticulate between the astraga-

lus and the scaphoid and between the os calcis and the cuboid, leaving behind the astragalus and os calcis, as in Chopart's amputation. Then the plantar flap is carefully dissected from the lateral and lower surface of the os calcis, so that it can be exposed as high as the sustentaculum tali, this part of the operation resembling the dissection round the heel in Syme's amputation at the ankle-joint. When the lower part of the calcaneum is thus fully exposed, it is to be sawn through just below the level of the sustentaculum, so as to make the line of saw-cut as near as may be at right angles to the line of the tibia when the patient is standing, and therefore parallel to the line of the ground on which it is to be placed. The section of the bone is recommended to be made from within outwards, thereby more surely avoiding any injury to the posterior tibial artery, which, from its important bearing on the life of the plantar flap, is to be most carefully guarded. Having made sure that the section of the bone has been made in the desired line, the sharp edges and corners of the bone are to be removed with cutting forceps, and the flaps brought into place and united by many sutures. Proper drainage-tubes being placed, and a supporting dressing applied, which shall hold the lower flap well in its place, the operation is completed.

I performed the operation in the following case: John Ohmer, a German, æt. 33, a waiter by occupation, was admitted to the New York Hospital April 18, 1882. His health had been good until about four months previous, when, without any known cause, his left ankle became swelled and painful. The trouble rather slowly increased, he continuing to walk about for nearly a month, when his ankle became so distressing to him that he took to his room and finally to his bed. The further course of the disease was one of steady increase, with increasing and finally severe and constant pain. On admission the tarsal region was recognized as the seat of the disease, the swelling, however, extending up to the ankle-joint. The swollen parts were very hard and tender to the touch, and the whole region was hot and painful, but without much redness of surface. After a time obscure, deep fluctuation could be discovered, and some crepitation could occasionally be elicited by moving the metatarsal bones on the tarsus. Deep incisions were made, letting out a great deal of pus. The part was poulticed, and everything was done that we could think of to improve his general nutritive condition, but without result. The abscesses did not heal; fistulæ remained; pain was not mitigated; in short, the carious disease was making constant progress.

On the 20th of May the actual cautery was applied at several points on the dorsum of the foot, but, beyond relieved pain, no benefit could be traced. The question of amputation soon decided itself, and inasmuch as we felt confident that disease was confined to the anterior row of the tarsal bones, it was regarded as a suitable case in which to make a trial of Tripier's method. The amputation was done on the 7th of June, precisely in accordance with the description given above. Particular care was taken to make the plantar flap as liberal as possible. All the fistulæ leading down to carious bone were included in the part removed, except one which remained on the inner side of the stump. When the disarticulation was accomplished the remaining bones were carefully examined, and were considered to be free from disease, and the section of the os calcis revealed bone tissue softened, indeed, from the atrophy of disuse, but as far as we could judge, free from present disease. The flap fitted exceedingly well, and covered the bone without the slightest tension. Everything proceeded to our entire satisfaction during the first few days after the amputation. The wound healed almost entirely by the first intention, and he improved very greatly in his general condition as soon as he was released from the irritation caused by the carious bones. The local conditions, however, did not long continue favorable. Part of the wound broke open and gave issue to pus, which, it was soon evident, came from a deeper source than the surface granulations. The stump became swollen and painful and it became clear that carious disease had attacked the astragalus, and probably the os calcis. His general condition began now pretty rapidly to depreciate, and though the operation wound was for the most part soundly healed, we were convinced that there was hopeless local disorganization of the bones, and that reamputation was the only thing that could save his life. The limb was accordingly amputated through the lower part of the leg on the 8th of August, just two months after the previous operation had been performed. He made a rather slow, but ultimately a perfect, recovery.

As far as the cure of the disease was concerned, Tripier's amputation, in this case, was not a success; the mischief spreading to the bones left in the stump, and requiring another operation for its eradication. This feature has, however, no particular bearing on the operation itself, which is the subject we are now considering, and it may be said generally that in all these partial operations on the foot and also on the hand, some uncertainty must exist—first, as to whether any disease of the bones has been left behind; or, secondly, whether the bones, now healthy, may not take on diseased action in the future. As a rule, I think this point ought, with care, to be determined with substantial accuracy, and, in point of fact, recurrence of disease has been found to be rare. I am aware that Mr. Syme says, "In this operation the astragalus and os calcis are left, and though they appear sound at the time of operation, yet the disease frequently recurs, as you may learn from the fact that I once performed three secondary operations within the period of twelve months upon stumps in which Chopart's operation had been practised." On the other hand, Mr. Hancock replies: "This objection, thus forcibly urged by Mr. Syme, is, I am aware, maintained by other surgeons, but it is not supported by the statistics of the operation; since, of 104 cases, exclusive of those mentioned by Mr. Syme, I find only two followed by secondary amputation, and this for retraction and painful cicatrix, and not for recurring disease."

The new operation seems to me to offer a satisfactory substitute for a very unsatisfactory one, such as in many cases Chopart's amputation is conceded to be. It is an operation not yet proved, scarcely fairly tried, and it would therefore be unwise to pronounce too positively on its merits. That it is feasible, that it makes a good stump, is settled by the few cases in which it has been done. That it certainly and perfectly obviates all the disadvantages of the amputation which it is proposed to displace, we cannot be sure. I can only say that, as far as theoretical considerations go, and as far as a very few cases can be trusted, it seems to promise well, and I challenge for it the careful consideration of those who may have occasion to perform a medio-tarsal amputation.

DR. POST referred to another operation which furnished better results, so far as usefulness of the limb was concerned, than did Chopart's—namely, that performed by Dr. Quimby, also claimed by Dr. Turnipseed, of South Carolina. It consisted in a modification of Pirogoff's operation, but differed from it in the fact that the lower extremities of the tibia and fibula were left entire, the cut surface of the os calcis being brought in contact with the cartilage covering the lower extremity

of the tibia. Dr. Quimby had performed the operation three times and Dr. Post had performed it twice, and in all the cases there had been a good stump and no inconvenience had resulted from want of homogeneity of the parts brought together. The wounds had healed kindly, the stumps had been firm, and the operation had been attended by only a moderate amount of shortening.

DR. L. A. STIMSON said the idea of the operation referred to by Dr. Post was not novel. It had been considered by Pirogoff himself, and, he believed, also by the English surgeon Ure, who devised the operation at about the same time as Pirogoff. The suggestion has been frequently referred to and generally condemned. The lower end of the bone is sawn off in Pirogoff's amputation, not because surgeons do not know that bone and cartilage can unite, but mainly because of the difficulty of otherwise keeping the end of the calcaneum from being drawn up by the tense tendo Achillis, the same reason that has led to its modifications in the direction of the line of section of the calcaneum or of both bones. Dr. Stimson asked if it had been found difficult to perform Tripier's operation.

The PRESIDENT remarked that there was no greater difficulty in the performance of the operation than obtained in Syme's or Chopart's, except with reference to following the line of the incision.

DR. MCBURNEY had performed Chopart's operation in one case, in which there was ankylosis of the ankle-joint, not produced by disease, but by long confinement in one position. The patient made an excellent recovery and had a useful stump. That fact suggested to him the question as to whether sufficiently strict attention had been paid to retaining the stump in proper position for a sufficient length of time after Chopart's operation had been performed. The idea was to retain it in position for a sufficient length of time to allow a certain loss of muscular power to take place, so that there would not be a marked antagonism between the anterior and posterior groups. He could easily imagine that the stump after Chopart's operation might bend downward within two weeks if allowed to follow its own course. He asked Dr. Markoe if he was able to give any information upon that point.

The PRESIDENT replied that, so far as he recollected, none of the authorities had directed attention to the question raised by Dr. McBurney. It seemed to him, however, to be a reasonable suggestion, and it also seemed to him that the mechanical factor, even with atrophy of both sets of muscles, the os calcis touching the ground first, was the great factor of the operation. Contraction of the muscles was probably another important factor.

DR. SANDS believed that the neglect to prevent this extreme extension of the foot after Chopart's operation had been recognized by European continental surgeons as perhaps the main cause of the subsequent difficulty in locomotion. He believed it had been claimed that, if extension of the foot was duly prevented during the course of the treatment immediately following the amputation, it would not subsequently take place to such a degree as to bring the cicatrix in contact with the ground, provided the former was not placed too near the plantar surface. He believed that the verdict given by American surgeons against Chopart's amputation had not been sustained by statistics. The statistics given by Max Schede proved that the limb, after Chopart's operation, was no more frequently useless than after other partial amputations of the foot; there were only ten per cent. of useless limbs after Chopart's operation. He thought that Chopart's operation was entirely legitimate, provided the astragalus and os calcis were both sound. There was an objection to both of these operations, Chopart's and Tripier's, namely, that when carious disease invaded the tarsal bones, it was apt to implicate, sooner or later, all of them, and thus there might occur, as in the case related, extension of the disease after performance of the operation, so as to render necessary amputation at a higher point. Some years ago, Mr. Hancock proposed, in cases of partial amputation, to regard the foot as a whole, and to operate without reference to the articulations, forming the flaps and sawing the bones as might be expedient. Dr. Sands thought that the suggestion made many years ago was particularly useful in these days of antiseptic surgery, when operation wounds, whether of bones or joints, were so likely to pursue a favorable course.

DR. WEIR supplemented Dr. Sands' remarks by the statement that Hancock also suggested the removal of a small section of bone, so as to counteract the contraction of the posterior group of muscles.

DR. BRIDDON said that within the last two weeks a patient came under his observation who had had Chopart's operation performed two years ago. Since that time he had been incapacitated in going about on account of painful ulceration in the line of the cicatrix; the whole of the anterior surface of the stump was covered with cicatricial tissue, and a spot about the size of a quarter of a dollar was in a state of ulceration. He thought the ulcerated condition was not attributable entirely to the operation, inasmuch as the operation had probably been performed in apparently healthy tissues. The original injury, however, was a railroad accident, and he, therefore, presumed that, as was commonly the case in railroad accidents, the vitality of the tissues was, to a greater or less extent, destroyed to a point higher than that at which the amputation was made, as some sloughing of the flaps took place, making them scanty and tense, and ulceration occurred after repeated cicatrization. As a further operation, he had recommended Syme's amputation.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting, January 3, 1883.

THE PRESIDENT, W. S. W. RUSCHENBERGER, M.D., IN THE CHAIR.

DR. JAMES C. WILSON made some

OBSERVATIONS ON THE MANAGEMENT OF ENTERIC FEVER ACCORDING TO A PLAN BASED UPON THE SO-CALLED SPECIFIC TREATMENT,

which he has employed during the past year, and which, tested by such uncertain but not necessarily fallacious means as are available for a limited series of cases, has yielded satisfactory results.

The Plan of Treatment.—The management by medicinal means, super-added to the so-called rational and expectant method in general use in this community, differs from the common practice, and constitutes the plan in question. So soon as the patient's symptoms warrant a reasonable suspicion that he is about to develop enteric fever, he is put to bed, ordered a diet consisting of milk, animal broths, jelly and simple custards, in small amounts and at intervals of two or three hours. At night he is given a dose of calomel. This dose varies in amount from 7½ to 10 grains, and is repeated every second evening until three or rarely four doses have been administered in the course of the first six or eight days. It is given alone or in connection with sodium bicarbonate. There is commonly a slight increase of diarrhœa, if it be present, without aggravation of the other symptoms, and in some instances the tendency of the temperature at this time to steadily rise appears to be controlled. If, as is frequently the case, spontaneous diarrhœa has not re-

curred in the first week, the calomel usually brings about two or three large evacuations on the day following its administration, not more. In either case, the tendency to frequent passages in the later stages of the attack is favorably influenced by the repeated administration of this drug during the first week. If the case does not come under observation until after the tenth day, one only, or at most two doses of calomel are given. No further doses of it are, however, given during the course of the attack unless constipation occur. In this event, if the evidences of extensive or deep implication of the intestinal wall, such as abdominal pain, tenderness, or marked tympany are absent, calomel in 7½-grain doses is given at intervals of three or four days. If there is reason to suspect serious intestinal lesions, the lower bowel may be more safely emptied of its contents every third or fourth day, by enemata of moderate size (8 to 10 fluidounces). It is necessary to bear in mind that the gravest lesions of the gut, leading even to hemorrhage and perforation, have occasionally been observed in cases characterized, not only by constipation, but also by an entire absence of pain or tenderness, and very moderate tympany. The danger of salivation from calomel in these doses in enteric fever appears to be slight. In only one case in sixteen were the mercurial fetor and slight swelling of the gums observed.

Excessive diarrhœa has been controlled by the use of opium, in suppositories or by the mouth, often associated with bismuth. It is an invariable rule that the patient be kept in the horizontal position and to the use of the bed-pan and urinal, from the time of the recognition of the disease until defervescence is completed. He is, however, turned upon his side from time to time, and made to maintain that position for twenty or thirty minutes, if necessary, being supported by the nurse.

From the beginning of the attack the following mixture is regularly administered in doses of one, two, or even three drops in a sherryglassful of ice-water after food, every two or three hours during the day and night.

℞.—Tinct. iodinii, ... f℥ij.
Acid. carbolici liq., . . . f℥j.—M.

Unless some unusual circumstance occurs to render a change necessary, this medicine is not suspended until the attack draws to a close. It is well borne by the stomach, and in one case only has it been necessary to omit the carbolic acid on account of the disgust caused by its odor.

Partly for the sake of its favorable influence upon the skin and for the sake of cleanliness, partly because of its favorable though slight influence upon the temperature, the patient is to be sponged twice a day with equal parts of aromatic vinegar or alcohol, and cold water. If it is more grateful to him, this sponging may be done with tepid water.

When the evening axillary temperature reaches 104° F., quinine in massive doses, 24 to 30 grains, is given upon a falling temperature. I usually direct 8 to 10 grains to be given in solution at 5, at 5.30, and at 6 A.M. the following morning. Administered thus at the decline of the temperature in its diurnal revolution, these large doses of quinine depress it from 2.5° to 3.5° F. After the lapse of forty-eight to seventy-two hours, if necessary the dose may be repeated. If these doses be rejected by the stomach—an unusual circumstance—half the quantity of quinine may be administered hypodermically. For this purpose a citric acid solution is to be preferred. Since the adoption of the plan of treatment under consideration, I have not encountered cases attended with such hyperpyrexia as has rendered attempts to control it by cold baths necessary or even advisable.

The minor nervous symptoms are best held in check by skilful nursing. For the relief of the headache of the first ten days absolute quietude, a dim light, etc., are often sufficient; occasionally the bromides alone or in combination with chloral are required. Later in the course of the disease chloral is unsafe. From the end of the first week the patient cannot be left unattended even for a few minutes, without risk. Persons in whom delirium was only occasional and transient, have in many instances destroyed themselves during the momentary absence of the nurse.

Alcohol is not often indicated prior to the beginning of the third week. It is commonly administered, usually in small amounts, towards the close of sickness. Some patients do well without taking it at all. It is, of course, administered in accordance with well-understood indications upon the supervention of delirium, ataxic symptoms, and the evidences of failure of the forces of the circulation. The patients are carefully watched well into convalescence, and cautioned against too soon regarding themselves as restored to health.

The dangers of the establishment of a focus of contagion are guarded against by the systematic, thorough disinfection of the stools immediately after they are voided.

The considerations which led Dr. Wilson to adopt this plan of treatment are:

1. A feeling of dissatisfaction regarding the expectant method of treating enteric fever, based upon the high death rate.

The percentage of fatal cases rarely falls below 15 per cent., and often exceeds 25 per cent. Jaccoud, with a collection of 60,000 cases, observed a mortality of 20 per cent.; Murchison, in 27,051 cases, 17.45 per cent.; Liebermeister, in 1,718 cases at Basle, under an expectant plan, records 27.3 per cent. of deaths. But turning from broad generalizations to personal experience, who is there here that, many times elated by the happy issue of mild or average cases treated by the expectant plan, has not realized the sense of utter powerlessness attending it when he has stood face to face with cases in which *to do*, rather than *to wait*, has been necessary to save life?

2. Enteric fever is the very type of the general diseases, of affections *totius substantiæ*. The tissues are universally implicated in the morbid processes; no function of the body wholly escapes perturbation. For this reason plans of treatment suggested by the prominence of certain groups of symptoms, or by the known lesions of particular organs, even though of undoubted benefit as far as they go, are in theory unsatisfactory, because they are directed in effect against conspicuous manifestations of the cause of sickness rather than against the cause itself.

Whilst in actual practice the treatment by turpentine, by alcohol, by opium with lead, or the silver nitrate, or by agents capable of controlling the febrile movement, as quinine, digitalis, salicin, and the salicylates, even the cold-water treatment itself, although at times and in the hands of certain clinicians showing favorable results—all these have failed of general acceptance on the part of the profession.

3. The general character of the disease, the specific nature of its cause, the unsatisfactory results alike of an expectant and of a symptomatic plan of treatment, or rather of the two combined, have united to render the idea of a specific treatment, a true cure for enteric fever a most attractive one, to stimulate thoughtful observers to renew again and again the disappointing search for it. To this idea may be traced the treatment by the mineral acids, by chlorine water, by carbolic

acid, by quinine alone, by quinine and digitalis, by iodine, by the potassium iodide, by calomel.

4. Not only is the conception of a specific treatment for specific diseases a most attractive one, and the attainment of such a treatment for enteric fever brought within the bounds of a reasonable hope by the analogy of syphilis and the malarial diseases, but the search after it with due caution and judgment has also the warrant of the very highest medical authority.

The treatment advocated consists of the use of the two remedies that are proved to exert a favorable influence upon the disease, iodine and calomel, with the addition of carbolic acid in minute amounts. The results of this treatment encourage Dr. Wilson to hope that they will lead to its trial on a more extended scale. That it amounts to a specific treatment in the narrow sense is not affirmed.

The *total number of cases treated* by Dr. Wilson by this plan is sixteen; all recovered, one being now in the second week of convalescence. Of these, eight were severe, the temperature reaching or exceeding 104° F. Of these, one was characterized by uncontrollable vomiting in the third week. The patient retained no food taken by the mouth for five consecutive days. One case was very irregular in its course, and was complicated by an obscure abdominal abscess which discharged by the bowel. The temperature in this case on two occasions attained 105° F. A third case was prolonged by a severe relapse.

Of the eight cases in which the observed temperature did not at any time attain 104° F., one was complicated by crural phlebitis, and another by the occurrence of intestinal hemorrhage.

The average duration of the eight severe cases was about thirty-one days; that of the eight mild and medium cases was about twenty-five days.

Of the whole number, ten were treated in hospital, six in private practice.

In two cases the special plan of treatment was abandoned about the beginning of the third week on account of the supervention of unusual symptoms of great gravity. These related respectively to gastric irritability and an obscure abdominal abscess.

These sixteen cases are unfortunately not a consecutive series. During the year in which Dr. Wilson has had the opportunity of observing them, two other cases of enteric fever occurred in his hospital practice in which this plan of treatment was not employed. One was previously greatly reduced, and was not regarded as a suitable subject for a special treatment, the efficacy of which was not yet established. The other, with an obscure history of a sickness of many weeks, and a very irregular temperature, developed the typhoid eruption, and within forty-eight hours had general peritonitis. These two fatal cases have, however, no bearing upon the result of the treatment.

In private practice several cases of mild continued fever of long duration were treated upon this plan. They are believed to have been anomalous cases of enteric fever, but as the rose spots of that disease were absent, and their departure from the typical disease was wide, they were not included. They all recovered.

The result of this plan of treatment has not only been satisfactory in respect of the recovery of all the cases treated, an accidental circumstance not liable to mislead persons familiar with the disease, but it has also been satisfactory in respect of the general course of the attack, and the appearance of the patient. These were in the main, despite the severe type of the disease in several of the cases and despite the occurrence of grave complications, favorable. Dr. Wilson made this statement with due regard to the personal equation, and with no willingness to permit the observed fact to differ from the actual fact, for he desires any who may make trial of this plan to be more favorably impressed with the results of it, than with his account of it.

Dr. Roberts Bartholow said that this plan of treatment is in part the so-called "specific" method. The administration of calomel in full purgative doses during the first week serves a double purpose: it has an effect on the range of temperature, and it acts on the typhoid germs present and multiplying in the intestinal canal. The use of iodine—usually Lugol's solution—throughout the disease, is also one mode of the specific treatment. By the use of this medicine, it is attempted to prevent the multiplication of germs in the intestine, to check fermentation, and to maintain an antiseptic action in the blood. Although the existence of typhoid germs has not been proved, it must be regarded as possible. Klein, a few years ago, announced the discovery of the specific organism of typhoid in the affected intestinal glands, but Creighton, of Cambridge, showed that the supposed germs were produced by the mode of preparation. This *fiasco* threw great discredit on the whole question of germs. Nevertheless, the course of treatment directed against supposed germs—the antiseptic method—has had a most favorable influence on the progress and mortality from typhoid. Whilst the specific plan has been advocated in Germany, the Montpelier school has brought forward carbolic acid as the remedy, and the success which has attended its use has been really remarkable. Quite a different complexion has been put on the statistics of mortality since they began the use of carbolic acid. It is probable that the combination of carbolic acid and iodine gives better results than the use of either singly. According to my observation, this method of treatment diminishes the diarrhœa, lowers the fever, and renders the disease much less violent, consequently lessening the mortality. Dr. Wilson has, therefore, rendered us a real service by drawing attention anew to this plan of medication, and especially by supporting his position with valuable cases and statistics. Besides this use of medicines, Dr. Wilson's treatment contains many valuable suggestions and practical methods, which, no doubt, contribute materially to his success.

Dr. J. M. Da Costa spoke of the purgative treatment in enteric fever, as that which had been tried in the French hospitals, and for a time sanctioned by Louis. As regards calomel, it was partly by its purgative action that it was supposed to be beneficial. In his hands the calomel treatment had not yielded favorable results. He had found carbolic acid useful in controlling diarrhœa and in lowering the temperature. He had also employed thymol in one-half to one-grain doses. He suggested the use of this remedy in the place of carbolic acid, as more acceptable to the stomach.

Dr. Wilson called attention to the fact that carbolic acid and like drugs probably exert a favorable influence upon the course of enteric fever by their power to stay the rapid decomposition of the intestinal contents, which, for lack of the antiseptic influence of the intestinal juices, the bile, etc., all of which are changed, is a secondary cause of irritation, diarrhœa, and tympany. Calomel also, he thought, probably exerted an indirect beneficial influence in the same direction.

CORRESPONDENCE.

THE APPROPRIATION FOR THE ARMY MEDICAL MUSEUM AND LIBRARY.

We have received from Dr. A. B. Isham, of Walnut Hills, Cincinnati, the following note addressed to him

by the Honorable Mr. Butterworth, in relation to the note relative to the appropriation for the Army Medical Museum and Library, given in the number of this journal for December 30th, page 738.

We are very glad to learn that we have been misinformed as to the attitude of Mr Butterworth relative to this interest. In the last number of this journal, January 13th, page 59, the full debate in the House relative to this appropriation was given, and Mr. Butterworth's remarks as there reported fully sustain the statements in his letter.

HOUSE OF REPRESENTATIVES U. S.,
WASHINGTON, D. C., January 6, 1883.

MY DEAR DOCTOR: Your letter of the 3d is received. THE MEDICAL NEWS was not possessed of accurate information. So far from reducing the appropriation, I moved its increase over what the Committee had allowed. I am aware of the great value of the Museum, and am only sorry that no suitable fireproof building has been provided for it.

I thank you for the kind expressions contained in your letter, and with best wishes, I am

Very truly yours,
BENJAMIN BUTTERWORTH.

A. B. ISHAM, M.D.,
(Walnut Hills, Cincinnati, Ohio.

MUSCLE-READING.

To the Editor of THE MEDICAL NEWS.

SIR: A recent issue of your journal contains a report of some of my more recent experiments in muscle-reading, which, together with the comments made thereon, are founded on a misunderstanding of the nature of my experiments.

I understand you to say that there is in these experiments danger of being deceived. This is precisely not the case. Muscle-reading experiments are as accurate as anything in mathematics; they are indeed a part of mathematics itself. The beauty and the power of these experiments in muscle-reading consist in their precision, in the impossibility of being deceived, in the certainty of the results, and in the firm knowledge which the experimenter has that he has not been cheated by anybody, not even by himself.

It is quite true that many of the phenomena of artificial trance or hypnotism can be simulated; but the phenomena of muscle-reading, whether done by a person in trance or out of trance, cannot be simulated, as all authors all over the world who have studied the subject agree; even a non-expert can understand this after a short process of experimentation. If those who have not an opportunity of experimenting themselves on this subject, or of witnessing the experiments of others, will read what I have published on the subject years ago in *The Popular Science Monthly* (February and July, 1867; and *Journal of Science*, July, 1881, London), and in other journals, or will read the reports of the members of the Royal Society of England (Francis Galton, Ray Lankester, M. Romanes, and Prof. Robertson), who experimented in the same direction (*Nature*, June 23 and July 14, 1881), and who obtained results precisely similar to mine so far as they went, they will find that there is nothing in science more accurate than the results obtained in these experiments. The special object of these later experiments was to determine the extreme minuteness of the localities that can be found by means of artificial appliances. The details will soon be published in a scientific journal.

I hope, however, that the readers of your journal will not content themselves with the experiments of others on this subject, but experiment for themselves independently; subjects can be obtained everywhere, and they will find results as hertofore stated. I trust also they will do what is possible to enlighten the public, as well as professional and scientific men, on this theme. The strongest friend of quackery of all kinds, and the strongest enemy of our profession, in this country especially, but more or less in all countries, is ignorance of the action of mind on body. The best single answer to the delusions that sustain quackery that I know of is found in these muscle-reading experiments; in the rapidity, the precision, the delicacy, the certainty to which they can be carried on they show more powerfully than anything else I know of in science the interdependence of body and mind, and suggest the true explanation of the success of nearly all the forms of charlatanism in all ages. Withal, these experiments, which when they were first made were an original contribution to science, have a direct and positive value for physicians who rightly understand them; the suggestions they give are of practical as well as scientific service to our profession, and especially to psychologists.

It is now eight years since I made my first experiments in this department of science. The interest in the subject has increased to such a degree that there is already quite a literature on the subject, particularly in England, and in the past year the German psychologists are beginning to look into the matter. There is no danger that physicians will study it too much; there is much danger of studying it too little, and giving too little heed to the important practical suggestions which it offers. GEORGE M. BEARD.

NEW YORK, January 10, 1883.

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

A NUMBER OF SUPPOSED CASES OF TYPHUS FEVER were discovered in a Hester Street tenement house by the Board of Health, and it was found that there had been no less than six deaths in a few weeks. The disease was typhoid, and not typhus fever. The locality is one of the worst in New York, and this outbreak should be a warning to the authorities.

A NEW SOCIETY OF MEDICAL JURISPRUDENCE has been established by the dissatisfied seceding members of the Medico-Legal Society; among them Drs. Hammond, Spitzka, Morton, and a number of Brooklyn physicians. Dr. Wight, the Professor of Surgery at the Long Island Hospital Medical College, read a paper upon "Illusions and Hallucinations as Affecting Testamentary Capacity," at the inaugural meeting.

THE NEW CODE.—There is much sharpening of knives and burnishing of armor upon the part of the delegates who are to go to the State Society. The outside County Societies are repudiating the action of their delegates who went to Albany last year. Several medical men, not entirely unknown in medical politics and post-graduate instruction, are determined to make a bitter fight for the New Code.

THE ILLNESS OF MISS LILLIAN RUSSELL, a popular comic opera singer, brought forth a column of interview in the *New York World* the other day. Miss Russell seems to have been treated in sections by a dozen or more of the regular physicians and homœopathists, all of whom pursued a different plan of treatment, and abused each other roundly. The stage manager of Miss Russell objected because one of these gentlemen gave her 120 grains of quinine *per diem*.

THE GOVERNMENT'S MEDICAL EXPERTS IN THE GUITEAU CASE, many of whom gave a month of their time to the trial, have not been compensated yet, although over a year has elapsed. The lawyers have been paid, and it is difficult to see why an exception should have been made entirely in their favor.

POUGHKEEPSIE, N. Y.

(*From our Special Correspondent.*)

THE DUTCHESS COUNTY (N. Y.) MEDICAL SOCIETY AND THE NEW YORK CODE.—At the annual meeting of the Dutchess County Medical Society, held at Poughkeepsie on January 10th, it was

Resolved, That the Medical Society of Dutchess County instruct its delegates to vote in favor of repealing the Code passed at the last meeting of the State Society.

TROY, N. Y.

(*From our Special Correspondent.*)

RENSSELAER COUNTY (N. Y) MEDICAL SOCIETY AND THE NEW YORK CODE.—At the annual meeting of the Rensselaer County Medical Society, held January 9th, the following resolutions were adopted by the Society:

Resolved, first, That this Society affirms its loyalty to the Code of the American Medical Association.

Second, That it directs its delegates to vote for the restoration of the Code of the American Medical Association.

CHICAGO.

(*From our Special Correspondent.*)

PRELIMINARY EXAMINATIONS.—It has been known for a number of months that after the present course of lectures our State Board of Health would not recognize the diplomas of colleges which do not require an entrance examination of its students. Hereafter, graduates from colleges which do not have this requirement will be obliged to undergo a special examination before the State Board in order to be admitted to practice in Illinois. The four regular schools here require preliminary examinations.

TRAINING SCHOOL FOR NURSES.—This organization, now only about two years old, has become so much of a success at the County Hospital, that citizens have contributed funds enough to buy a lot and commence the building of a permanent Home for the school, within half a block of the college. Probably no good organization, touching in its work the practice of our profession, has ever been started among us which has worked more quietly and modestly than this, and certainly no other has, in so short a time, established itself on so firm a foundation of public confidence in its value and usefulness.

A NEW CHAIR OF LARYNGOLOGY.—Rush Medical College has just created a special chair of laryngology and elected Dr. E. Fletcher Ingals to fill it, with the title of Professor of Laryngology.

NEW ORLEANS.

(*From our Special Correspondent.*)

HEALTH OF NEW ORLEANS.—This city is not as healthy as it usually is at this time of the year. One hundred and sixty-three deaths occurred last week.

The most serious diseases prevailing are pneumonia, some of the eruptive fevers, and cerebro-spinal meningitis. It is reasonable to suppose that the holidays are in part chargeable with this increase of mortality. The festivities of Christmas and New Years bring such fruits as pneumonia and cerebro-spinal meningitis from exposure to cold; and the eruptive fevers by disseminating their special poisons throughout those assemblages which hilarious occasions bring together.

The deaths from smallpox average about ten a week; scarlatina is much less prevalent. Four cases of cerebro-spinal meningitis have been admitted to the hospital within the past ten days. One of these, which was apparently the most furious at date of admission, suddenly abated, and the patient has been discharged, well. It is a well-known fact that in some autopsies of patients who die from cerebro-spinal meningitis, no lesions are found to indicate that the inflammatory process had gone beyond the stage of engorgement. We may from this understand how it is that well-marked and threatening symptoms may sometimes stop short of death, or of such an amount of effusion as to make recovery slow. Two of these cases were under your correspondent's charge. They were treated by bromide, potash, and ergot in the first stage: by iodide-potash in stage of effusion.

Pneumonia is a fatal disease in all large hospitals. It becomes still more so if the hospital be located in a place where malaria is so rife that every case treated is complicated by its presence or influence. But in spite of these difficulties which we have to meet, the mortuary reports of the hospital show very favorably when compared with the death-rate of the city.

DEATH OF DR. WARREN STONE.—The early days of the present year instanced the death of Dr. Warren Stone, the son of the late Prof. Warren Stone. He was very largely endowed with the talents and noble traits of character which distinguished his father. The medical profession of New Orleans and a large circle of non-professional friends deplore his loss.

TORONTO.

(*From our Special Correspondent.*)

MORAL INSANITY.—At the December meeting of the Toronto Medical Society, the veteran Dr. Workman, late Superintendent of the Toronto Asylum for the Insane, read a long and very interesting paper on moral insanity, in which he said: "The term *moral insanity* was introduced into alienistic literature by Dr. Pritchard, an English writer, in 1835. Previously, Pinel, of Paris, to designate cases apparently identical, had styled them '*manie sans delire*.' His pupil, Esquirol, preferred the term '*manie raisonnante*.' This, to the vast majority of lay readers, must have appeared a very absurd designation, for the vulgar conception of insanity is that its subjects are incapable of reasoning, a belief which has been found very erroneous by many visitors of asylums who have ventured to address the inmates as if regarding them all as utterly mindless beings. Pinel's *manie sans delire* was a term quite applicable to a large proportion of all the insane, that is, in certain phases or intervals of the malady, but it would certainly be found to fail to cover the whole history of his cases. Insanity almost invariably has its inception in a change of the feelings or moral sentiments of its destined victims. This is its usual prodrome; but it is only when abnormality of the intellect has become manifest that the real disease is recognized by the friends of the patient, and too often, even then, it is not admitted by the neighbors, or the community, for outside of his own domestic circle the patient's language or actions may appear quite rational. When the insane commit crime, in almost all instances, the quality of the offence is judged of, not according to their actual mental state, but according to its nature or enormity; and it is very well known that the crimes of the insane are sometimes shockingly enormous. Why should they not be so?

"Pritchard's *moral insanity* might, with more propriety, have been called *insane morality*. Of the seventeen cases adduced by him, hardly one will bear the test of strict analysis. Some degree of intellectual debility or impairment may be detected, by an experienced reader, in every one of them, and several exhibited very palpable defects; one, indeed, perhaps his most accentuated, terminated in general paralysis, an invariably fatal form of insanity and one which, in its early stage, is often characterized by gross departures from moral propriety."

Dr. Workman, in the latter part of his address, gave the history of several cases of the *so-called* moral insanity which had come under his own observation, or had been recorded by his alienistic *confrères*. The details were very instructive. He concluded by earnestly admonishing his professional brethren, when unfortunately they might have to appear in Court as expert witnesses, never to fall into the inadvertence of using the term *moral insanity*.

INTERNATIONAL MEDICAL CONGRESS, EIGHTH SESSION; COPENHAGEN, 1884.—Prof. P. L. Panum, President of the Organizing Committee of the Congress, and D. C. Lange, Secretary-General, announce that, in accordance with the desire expressed by the International Medical Congress at its seventh session in London, 1881, that the eighth session of the International Medical Congress will be held in Copenhagen during the days from the 10th to the 16th of August, 1884.

FEES OF THE GUITEAU TRIAL EXPERTS.—The Department of Justice has decided on paying the experts summoned by the Government in the Guiteau trial at the uniform rate of $25 a day, with the ordinary witness fees in addition, but no other allowance for expenses. It was felt that the Government could not undertake to distinguish between experts according to their supposed rank in the profession or their comparative eminence, but must be governed by the length of their service. The bills ranged all the way up to $100 a day. The whole amount to be paid to the experts, exclusive of the ordinary witness fees, will be between $12,000 and $13,000.

Mr. Brewster Cameron, who has the matter specially in charge, intimates that any experts who were especially connected with the preparation of the case may receive an additional allowance on that ground. There were four of these—Dr. Gray, of Utica; Drs. Macdonald and Allan McLane Hamilton, of New York, and Dr. Kempster, of Wisconsin.

A TRAINING SCHOOL FOR NURSES is to be attached to the Kings County Hospital, on the plan of the one at Bellevue.

NATIONAL ASSOCIATION FOR THE PROTECTION OF THE INSANE AND THE PREVENTION OF INSANITY.—The annual meeting of the National Association for the Protection of the Insane and the Prevention of Insanity will be held at the hall of the College of Physicians of Philadelphia, on January 25, 1883, at 3 and 8 P.M. The address of welcome will be made by Dr. S. D. Gross. Papers will be read by Drs. Traill Green, J. S. Jewell, Charles K. Mills, Milner Fothergill, and others.

THE MONTHLY BULLETIN OF THE MORTALITY AND SANITARY CONDITION OF LOWELL, MASS., differs from most of its contemporaries, which are strictly statistical, in containing short but excellent articles intended for popular education in sanitary subjects. The issue for December discusses "Preventable Disease" and "School Hygiene."

THE JOHNS HOPKINS UNIVERSITY.—PRESIDENT GILMAN has just issued his seventh annual report, covering the session of 1881–82. The University is stated to be in a flourishing condition. There has been considerable original work accomplished during the year in the different departments.

DR. REMSEN'S attention seems to have been confined principally to analyzing the drinking waters of Baltimore and Boston with a view of remedying their disagreeable taste and odor. His work has been very successful, particularly at Boston, where he showed the cause of the trouble to be a fresh water sponge, *spongilla lacustris*. In addition to the general course in biology, there is a course preliminary to the study of medicine which has been well attended. It is hoped that the time is not far distant when the medical department in connection with the Johns Hopkins Hospital will be organized. The work accomplished here in biology has been extensive. Dr. Martin, since his connection with the University, has paid special attention to researches in physiology, and has devised a new method of studying the mammalian heart. He has succeeded in keeping the heart alive for five or six hours after the death of the animal, and now any external influences upon this organ can be investigated much more satisfactorily than heretofore, when biologists had to confine their experiments to the hearts of batrachia.

The appendix to the report contains a full list of Fellows since 1876, and a complete bibliography of all articles and books published by members of the University.

When it was determined to build the two new laboratories, the board of trustees was divided on the question of location, some favoring Clifton, others the present situation in Howard Street. As they are being built in the city, it would seem that the University will be permanently located in Baltimore, and not at Clifton, as was the founder's intention.

The Johns Hopkins Hospital is about a mile directly east from the University. The towers of the administration buildings can be seen from all prominent parts of the city. The buildings most needed at present are virtually completed. Seven of the twelve wards are almost ready. Five of these are free, and can accommodate with the greatest ease 156 patients. The other two are pay-wards and furnish room for thirty-two beds. These wards are to be supplied with all the modern improvements. The construction of the elaborate system of ventilation has been directed by Dr. John S. Billings, United States Army. Fifteen buildings have up to this time been erected, the ground inclosing them being a plot of fourteen acres. In addition to the wards the administration, nurses' kitchen, autopsy and medical school buildings are completed. All are of the Queen Anne style.

WEST VIRGINIA STATE BOARD OF HEALTH.—Governor Jackson in his biennial message to the Legislature, dated January 10, 1883, refers to the Health Board of the State as follows:

"The law establishing the State Board of Health and regulating the practice of medicine and surgery, as amended and re-enacted last winter, has proved a wise act of legislation. It is admirably adapted to secure the protection of the lives, health, prosperity, and happiness of all classes of the people. It has met with the sanction of eminent sanitarians in other States, who have become acquainted with its provisions. The law is now in force in every county of the State, and we may reasonably expect that its operations will prove of much benefit. The number of registered physicians and surgeons to date of report

is 1,041. Of these, 958 are residents of the State and the residue residents of adjoining States.

Besides the careful protection of the interests of the life and health of the inhabitants of the State, the Board is charged with the duty of investigating the causes of diseases occurring among the domestic animals. The value of this provision of the law was witnessed in Brooke County last summer, when what is known as the Southern cattle fever made its appearance in that county. The prompt action of the State and County Boards arrested the spread of the disease, and probably saved large sums of money to farmers of that locality, in the preservation of their stock from infection."

DISINFECTION BY HEAT, AND ITS PRACTICAL APPLICATION.—The superiority of heat over all fumigations and other reputed disinfectants is now generally recognized, and local sanitary authorities have already in many districts set up disinfecting ovens or chambers of one or other kind. It is, however, of the utmost practical importance that the intensity and duration of the temperature required for the destruction of bacilli and of spores should be fully appreciated and attended to, if such "disinfection" is to be really effective, and not a dangerous delusion. DRS. R. KOCH and WOLFFHUGEL, after a long course of carefully conducted experiments, find that bacteria are not killed until after an exposure of one hour and a half to a temperature of 100° C. (212° F.). Spores of fungi require a greater heat, viz., 110° to 150° C. (230° to 300° F.), for at least as long; while nothing less than a temperature of 140° C. (285° F.), continued for three hours, suffices to kill the spores of bacilli, as those of anthrax. These are the germs with which we have to deal in practical disinfection. Such a temperature will, in three hours, infallibly kill these spores, but since it takes that time to penetrate to the centre of even small bundles of clothes, or of pillows, a further exposure of like duration will be required for their complete disinfection, and few articles of clothing or bedding will bear such treatment without serious damage. It is to be regretted that Drs. Koch and Wolffhugel did not repeat their experiments with moist air, for there seems to be no reason to fear that the presence of a proportion of vapor not amounting to saturation can detract from, if indeed it do not actually enhance, the efficacy of the heat; while it is known that the most delicate fabrics, as ostrich feathers, dyed silks, etc., are uninjured by a temperature of 300° Fahr. under these conditions, and if the moist air be forced in under pressure, as in W. Lyon's apparatus, the penetration of the heat is greatly facilitated. The general conclusion to be drawn from these experiments, which are described in detail in the *Mittheilungen des k. Gesundheitsamte*, Bd. i., seems to be that nothing less than a three hours' exposure to a temperature little short of 300° Fahr., with precautions to insure the penetration of every part of the articles subjected to it, is sufficient. How this is to be attained is a question of detail, but at present it certainly appears that preference is to be given to the particular apparatus above named.—*Medical Times and Gazette*, Nov. 4, 1882.

SMALLPOX IN SOUTHERN AFRICA.—Reports recently received from Cape Town state that the epidemic with which the city and neighboring villages have been scourged during the past few months is now abating. There were admitted into the Lazaretto from the commencement of the outbreak until October 30, 1,015 patients, but these constitute only about one-eighth of the whole number who have been affected. Of the 1,015, 253 were white, and 762 colored. Of the whites, 183 had been vaccinated at some previous time, and 70 were unvaccinated. Of the colored, the corresponding numbers were 180 and 582. Among the whites 49 deaths took place, 23 of the patients in these fatal cases having been vaccinated, and 26 unvaccinated. Among the colored people 252 fatal cases occurred, 31 having undergone previous vaccination, and 221 never having been vaccinated.

	Admitted.	Died.	Percentage.
Vaccinated,	363	54	14.87
Unvaccinated,	652	247	37.88
	1,015	301	29.65

Difficulty was experienced in procuring reliable vaccine virus.

At St. Paul de Loundu the disease is progressing. During the month of October 150 cases of smallpox were registered, of which 80 proved fatal. The population is estimated at 12,000. The sanitary condition of the town is represented as of the worst possible character.

CHOLERA, PREVENTION AND CURE IN CHINA.—The United States Consul at Foochow, China, in a recent official report, gives information derived from native physicians concerning the cause and treatment of cholera. The disease is conceived to arise from unseasonable weather and a lack of harmony between the upper and nether worlds, so that men living between the two are exposed to and suffer from noxious influences; or it is caused by wraiths badly laid or of evil intent, who are boldly exorcised from houses and passages by nightly processions bearing the images of proper spirits. The villages quarantine against each other. Among the precautions to be observed in times of danger, we find that nothing must be eaten or taken into the stomach which is liable to cause diarrhœa or vomiting. Fats and oils must be avoided, and salted provisions used instead. Tea should be replaced by ginseng infusion. Exercise in the heated part of the day should be avoided. If all precautions fail, and the individual become affected, ginger, cassia, and aconite are administered, the black blood is let out from under the finger-nails by needle punctures, counter-irritation is applied to the arms by heated seeds, and finally, the umbilicus is burned to warm up the stomach and start the circulation of the blood.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending January 6, 1883, indicate that consumption, erysipelas, measles, pneumonia, and bronchitis have increased, that diphtheria and neuralgia have considerably decreased, and that intermittent fever, whooping-cough, inflammation of brain, remittent fever, and influenza have decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during the week ending January 6th, and since, at 18 places, scarlet fever at 15 places, and measles at 12 places. Smallpox was reported in Richmond, Osceola County, January 2d, and in Royalton, Berrien County, January 4th.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 8 TO JANUARY 15, 1883.

MUNDAY, BENJAMIN, *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Fort Klamath, Oregon.—*Par. 3, S. O. 195, Department of the Columbia, December* 29, 1882.

ORIGINAL LECTURES.

ESMARCH, ANTISEPSIS, AND BACILLUS.

The Annual Address, before the Philadelphia Academy of Surgery, delivered at the Hall of the College of Physicians, January 8, 1883.

BY WILLIAM HUNT, M.D.,

SENIOR SURGEON TO THE PENNSYLVANIA HOSPITAL.

GENTLEMEN: How does the statement, so often made in these times, that everything is practical and demonstrative, and that the days for didactic teaching and oratory are past, agree with the fact that there not merely lingers, but actually exists, an intense desire on the part of most people to hear something said by somebody, it too often seeming to be a matter of indifference whether what is said be good or bad, so that the desire is fulfilled? Does not the reason lie in the fact of the vast superiority of the sense of hearing, over every other sense, as a means of intellectual culture? Science demands demonstration, but demonstration requires explanation; pantomime alone will not do, otherwise the deaf and dumb should be our intellectual superiors. They are, however, shut off in a much greater degree than the blind from that capacity of association with their fellow-men which is so essential to high degrees of mental cultivation. We can demonstrate to deaf mutes, but we cannot do so to the blind. These say "*tell* us all about it;" the others, "let us *see* it." These will ponder with the subjective, and show that, hearing, they have understood, while with the others there is reason to believe the objectivity of objects remains without analysis, and for the most part seeing, they see not. The modern introduction of lip language promises a great compensation to these unfortunate ones. I can see no reason why a deaf mute with a healthy brain, one who simply cannot speak because he has never been able to hear, having learned the language of speech, instead of his own, which is essentially a foreign one of signs, should not become the peer of any of his fellow-men. It may be said that deaf mutes have all the requisites for cultivation in books, after they have learned to read. But reading of a high order, to one who only knows the language of signs, must be a labor indeed, and I should argue without having made practical inquiry that it would be very exceptional, and in most cases an impossibility.

In studying, then, the respective merits of the didactic and the demonstrative, the blind and the deaf give us the most striking contrasts. Great contrasts, also, teachers most sadly know, exist among those who pride themselves on the full possession of all of their senses. Dumb talkers and deaf hearers thrive in such numbers as to almost justify Carlyle's estimate of population being "mostly fools." It may be that a tacit acknowledgment of this by the wise ones of the world is the foundation of the immense advance of demonstrative teaching over the other and older method. The teacher seems to say, if I cannot *talk* a fact into your head, I can at least *show* it to you; and if with ears and eyes both you do not take it in, it is your fault and not mine! Who knows but what these proud demonstrators, who now so largely occupy the field of knowledge, may, when the concealing veil of truth is lifted, have to realize that they have been engaged in a fleeting *show;* while the dialectician, by contemplation led, is enabled to reveal that to which their work is as nothing and vanity.

And now I, who have always been a demonstrator, being forced for the first time, by the appointment of our unrelenting President, into a didactic position, must cast about for a theme with which to occupy the allotted time this evening.

Biography is justly the favored resort on such occasions, for what is more interesting and instructive than the following of the footprints of the great and learned ones of the past? Our two great leaders have already indulged us in this way. John Hunter and his pupils and Baron Larrey have been most vividly pictured to us. It is most tempting to follow the example, and I might take up Paré, or Cheselden, or Cooper, and discourse on the ligature, or lithotomy, or luxations, until my task was done. I might also go back, almost into the "night of time," and query as to what was then done for human ills, and show that medicine and the knife and fire were then, as they are now, at the command of those who had the skill, or the boldness, or the assumption to use them. But I shall choose none of these subjects, for my discourse will be devoted to a few of the occurrences of the past year, partly hackneyed and partly, I hope, fresh enough to interest you.

On the 2d of February, 1882, the distinguished Prof. Esmarch delivered a lecture at Kiel upon the "Treatment of the Wound of President Garfield." He was so kind as to send me a copy of this lecture. The high standing of the author and the lecture itself were looked upon as matters of such importance that, you will remember, they were made the subjects of a cable telegram to this country, and doubtless also to other places. A short statement of the opinions of Esmarch was given in the telegram. In his lecture the Professor states that he is led to select his subject from having noticed, through many English and American publications, that the widest difference of opinion exists among most distinguished American surgeons, both as to the wound and as to its treatment.

Short comments on five of the critics form the introduction to his paper. These, in the order named, are myself, from whom he opens the discourse with quite a lengthy quotation, from my letter published in THE MEDICAL NEWS, for Nov. 1881, which he characterizes as an attack upon antisepsis. Then follow the conclusions of Drs. Wm. A. Hammond, Marion Sims, John Ashhurst, Jr., and John T. Hodgen, taken from the celebrated and widely read article contributed by these four gentlemen to the *North American Review* for December, 1881.

In his concluding paragraph Dr. Hammond says, "it is denied that the wound was necessarily a mortal one," and that "the President did not have all the advantages of treatment which modern surgery is capable of affording." This much of that paragraph Prof. Esmarch quotes, and further on he says, "I must, upon the whole, adhere to the last proposition of Dr. Hammond, but, indeed, from an entirely contrary standpoint." He then takes the history of the case furnished by Dr. Bliss to the *Medical Record* of the 8th of October, 1881, and from it, and from the report of the autopsy, he seeks to establish his points.

I have never met Prof. Esmarch personally, but he must be a capital example of the effect of climate on character. His work has the snap of a Norseman in it, and is very different from the tedious disquisition

of many German writers. He was born at Tönningen, on the North Sea, but most of his life appears to have been spent at Kiel, on the Eastern shore—"by the wild Baltic's strand." In considering his subject, he gives a synopsis of the case from the materials at hand, and with abrupt, short, and sharp, if not always decisive, running comments, in the shape of foot-notes, he makes his thrusts. The reader who is not fond of foot-notes would miss the gist of the matter if he avoided them here. It would be interesting to know how they were managed in the lecture, as this, surely, could not have been delivered as printed; for, if so, much of its spice must have been lost.

The main point of the illustrious critic is, that *true* antiseptic treatment was not practised. The whole story is so familiar to us that I shall confine myself mostly, and therefore often abruptly, to the exact places where these pithy notes occur, and also, adopting the same style, I shall take the liberty of occasionally throwing in a note of my own, designating it with an H. The order will be a translation by me, back into English, of the parts of Esmarch's synopsis of Dr. Bliss's record, which are the especial subjects of his strictures; then Esmarch's notes; then my H's. After the record has been gone through with, only E. and H. will appear.

To begin: "The first physician who saw him (Dr. Townsend) carried his finger immediately into the wound; nevertheless, without finding the ball."

Note, "It is not stated that before this he washed and disinfected his hands."

H.: Railroad stations, as a general thing, do not keep twenty to forty per cent. solutions of carbolic acid on tap.

"The patient complained of a feeling of weight and numbness, later of pins and needles, and pain in the lower extremities."

Note, "Shock of the spinal cord."

"Dr. Bliss immediately examined the wound."

Note, "Nothing is said of antiseptic precautions."

"Then he carried the little finger of his left hand into the wound."

Note, "A dangerous operation without the spray."

"Thereupon he carried in a bent silver probe."

Note, "That it was previously satisfactorily washed and disinfected, is not stated."

H.: Clean hands and clean probes are at least as common in America as in Germany or Denmark. That "something is rotten in the State of Denmark," is a matter of common information.

"As the President was very desirous of being taken to the White House, a *temporary dressing*"—

Note, "What is that?"

H.: Why that is just what it says, a temporary dressing put on to last during transportation.

"In answer to questions, the President stated that the movement of the wagon did not cause any unpleasant feelings."

Note, "From which it is to be concluded that the spinal column was not separated."

H.: His attendants surely knew that much.

"As there was suppression of urine until six o'clock in the evening."

Note, "Urethral spasm."

H.: Better, insufficient or disturbed innervation from admitted spinal shock.

"A catheter was introduced and six ounces of clear, not bloody—"

Note, "Therefore, no injury to the kidneys."

H.: A good point in diagnosis

"The carbolized-cotton dressing had become displaced and must be renewed."

Note, "An *antiseptic* dressing could not have been so easily displaced."

"During the night the outflow of dark blood continued, and made frequent renewals of the dressing necessary."

Note, "The dressing could not have been very thick."

H.: I find nothing about frequent renewals at this time in Dr. Bliss's report, but if they were made, how thick should the dressings have been? It appears to me that the abundant first and wet organic discharges would soon, in the hot weather especially, have become a true outward nest for infecting germs, instead of theoretical ones in the room.

Drs. Agnew and Hamilton arrived July 4th. "The temperature was 37.8° C., pulse 104, respiration 19."

Note, "Therefore the whole condition was very satisfactory. In spite of this a renewed examination was made with probes, flexible bougies, etc., in order to determine the course of the ball."

Note, "What for? According to his report, Dr. Hamilton disclaimed any probing. It is not stated whether the instruments were properly disinfected or whether other antiseptic precautions were observed."

H.: Here is a question of fact, and here is an extract from a letter of Dr. Agnew's, dated December 5, 1882. I wrote to Dr. Agnew on account of remembering what he told me on his return from Washington after his first visit there. He says: "You are right; no examination was made by the consulting surgeons at the time of their visit. They were informed that careful explorations had been made at the time of the shooting by Bliss and by Wales. Bliss admits that he committed an error on this point, writing as he did in New York and without any notes to refer to." Of course, Prof. Esmarch is excusable, as Dr. Bliss's report was his source of information. But one of his severest strictures is thus swept away, and the expectant treatment, as we will find further on, which he so ardently advocates in such cases, and with which I am in full accord, was carried out to the letter.

To proceed: "They were convinced that neither the liver, nor the kidneys, nor the intestine, nor the peritoneal sac were injured, and refrained from any operative interference."

Note, "They might have known this without this examination."

H.: As the examination was not made, they appear to have been a fairly bright set of men, with average reasoning faculties.

"On the 21st of July a pus collection was discovered in the general integument which passed below the twelfth rib; towards the erector spinæ muscle, and underneath the latissimus dorsi; and the pus, with every change of the dressings, was carefully (Dr. Bliss says gently) pressed out towards the wound of entrance (Schussöffnung)."

Note, "Stromeyer and myself (references given) have most energetically spoken of the dangers of pressing pus out of wounds, especially, or namely, if splinters of bone are within."

H.: A very important thing to protest against, but I will again refer to this further on.

August 6: "A flexible catheter was passed downwards through the wound seven inches, towards the crest of the ilium. This was *now done twice daily* in order to rinse out the pus with an irrigator (hand fountain) filled with a solution of permanganate of potash."

Note, "In any case an obsolete and ineffective disinfection method."

H.: Whether this was done too often or not, those who were in attendance were the best judges of the requirements; also they were at perfect liberty to select their disinfecting fluid, and the permanganate of potash is a good one.

"In conclusion, Dr. Bliss remarks that the most approved antiseptic dressings were used during the entire progress of the case."

Note, "That, certainly, does not amount to much. There is a great difference whether one treats a wound with antiseptic *dressings*, or whether he treats it according to *antiseptic principles*. Against these much that is bad has been manifestly done here."

H.: Here are questions of fact, and the record to appeal to. Each one will have to judge for himself, though I hope not so harshly as the Professor has done, as to whether principles were subordinate to technic in the case.

Here follows a synopsis of the autopsy, illustrated by the familiar drawing of the perforated vertebra and fractured ribs. How any surgeon can look at that drawing and reflect upon the surrounding structures, which, if not directly, were by contiguity involved, and then say, not that it is not *possible* for a man so wounded to recover, but that he *ought* to recover, through modern methods properly applied, it is hard to conceive.

Then follow the conclusions of the Holstein Professor, thus:

E.: "1. President Garfield did not receive an absolutely deadly wound. The liver was not injured; the peritoneal sac was not injured; there was no peritonitis; altogether there was no important organ injured, *with the exception* of the *vertebral column!* The injury of the vertebral bodies was not of itself mortal. Healing might have readily occurred if putrefactive ichor (verjauchung) had not set in. *In military surgery there are examples enough of recovery from similar injuries.*"

H.: Instead of giving any such examples, here follows a long foot-note about deer shooting, thus:

Note, "Every hunter knows that the stag mostly survives a peculiar shot, the so-called hohlschuss. This is a shot by which neither the viscera, nor the great bloodvessels, nor the spinal cord are injured. As the great vessels lie directly below the faces of the vertebral bodies, and the spinal cord directly above them, the ball, in this case, must go directly *through* a vertebral body itself. If the cord is wounded, the stag, on account of the paralysis of his hinder extremities, cannot take to his heels when the hunter comes to give him the final stab.

"If the descending aorta or the inferior vena cava is injured, he does not fall immediately, but very soon after the shot, on account of the great hemorrhage. The 'Hohlschuss' is considered to be a bad one by the hunters, because by it they do not secure the game. It is also of no great consequence, because no surgeon comes to the rescue with fingers and probes, which carry corrupting causes into the wound."

H.: Allow me to suggest also that neither spray nor antiseptic dressings are at the service of the poor stag. "Pity 'tis, 'tis true." This is a point for the open method. To go on:

"Equally also the game is not killed or secured when it receives a shot that only wounds the spinous processes. In this case the stag falls because the hinder extremities are paralyzed momentarily by spinal shock. When the hunter approaches, however, the stag struggles forwards for some distance like a seal, with his forelimbs, and then suddenly springs up, and on all fours he runs away and is quickly out of sight."

H.: If the deer is so soon out of sight and if also those who have received the Hohlschuss escape, how do you know whether they die or not? Are they not as likely to suffer, and to languish, and to die in their solitudes, with such injuries, as human victims do in the open day? The laborious preparers of anatomical specimens, both human and comparative, so numerous in Germany, should be able to show some specimens illustrating recoveries of the kind the Professor mentions. I believe they would be very rare from the stag.

As to man, the matter has been gone over so thoroughly by most competent authorities that it is unnecessary for me to burden you with the tedium of statistics. Museums have been ransacked and records have been searched. I have done something at it myself, and notwithstanding the Professor's assertion that there are examples enough of recoveries from such wounds as that of the President, I feel no hesitation in here challenging him to produce a single *human specimen* unquestionably proving a recovery from a PERFORATING *gunshot wound of the body of a vertebra.* This deer note also requires further criticism. A shot is spoken of by which neither the viscera, nor the *great bloodvessels*, nor the spinal cord, are wounded. What does the Professor call the splenic artery two and a half inches from its origin at the cœliac axis, where it was wounded? I call it a great bloodvessel. I have prepared and mounted many a one, and we all know what a striking idea of great vascular supply to the spleen and neighboring parts is given by specimens of it. This artery wound was enough of itself to determine a fatal result.

To go on with the conclusions. E.: "2. The putrefactive ichor (verjauchung) cannot be laid to the ball, as it appears to have carried no septic substance into the wound, for it was already encapsuled and the neighboring part of its track was obliterated, that is, healed.

"3d. Therefore the foulness, the putrefying causes of the wound, must *have been brought in from without*, and for this, different points in the treatment are to be accused!"

H.: Is it logical in the search for the causes of phenomena, to abandon obvious and all-sufficient ones, and to substitute those which are vague, unproved, and theoretical? What a blessing it is to live and learn! In 1868, in the *Pennsylvania Hospital Reports*, in a paper called a "Contribution to the History of Toxæmia," I give an account of how I was poisoned and made seriously sick, from suddenly inhaling the fumes from an outburst of ichor, that gushed forth when I plunged my knife into a huge gluteal abscess. Innocently thinking that inward causes, possibly germs, may have been at the root of the trouble, I say, "we may imagine a micro-photograph taken of the material just as it gushes forth, picturing myriads of spores rising to a certain height and then falling dead like melting snow-flakes. The hapless victim who chances to be in the first part of the stream, catches up the living material, and affords a bed for its nourishment and propagation. Who knows, but what we may some day see such a photograph? Stranger things have happened."

My hopes of ever seeing such a picture have vanished, for I find I was altogether wrong. The spores were going the other way! I am told that, without having taken antiseptic precautions, the moment I made my cut, a myriad host of cocci rushed for the wound, and that some cowardly divisions as they passed me by, sought refuge in my mouth and air-passages, and insidiously poisoned me with their foulness. The invisible contest with the main army must have been fearful and altogether without the ramparts, and without quarter, for the gluteal sortie was successful, as the parts healed kindly and there was no evidence of prisoners. Notwithstanding my enlightenment, I have still a lurking belief that it was what came out of that man, and not what went into, or tried to go into him, that defiled both him and me.

To continue, E.: "The different points in the treatment that are to be complained of are:

"1st. The immediate examination of the wound with button probes and fingers, which were probably not disinfected (without antiseptic precautions).

"2d. The repeated examinations on the third day by several of the surgeons (probably so)."

H.: We have already dealt with this point.

"3d. The entirely insufficient antiseptic treatment of the wound (deficient in the technic of dressing).

"4th. The *squeezing* out of the wound undertaken from the 21st of July on."

H.: Nowhere, my dear Esmarch, in your synopsis of the record, nor in the record itself, does the word *squeeze* occur, but you take the deliberate liberty of substituting, in your summing up, "Ausquetschen" (to squeeze), for "Ausdrücken" (to press), and Bliss says, *gentle* pressure in one place, and pressure in another. Now, if you knew our beloved Dr. Agnew as we know him, you would know that he would not allow himself to *squeeze* any kind of wound, to work harm; nor would he allow others to do it if he could prevent it. In practice and in precept, he is most earnest against roughness of any sort. Shall I tell you, though, what I know he thinks? He thinks that, for a first-class squeezer, there is nothing equal to an Esmarch bandage, and it is on account of this very squeezing property that I have often heard him utter warning caution as to its use.

E.: "5th. After this the daily probing and syringing out of the wound with unsatisfactory antiseptic fluids (obsolete disinfection methods)."

"6th. The neglect of a radical division into the pus-cavity (8th August)."

H.: From Dr. Bliss's account, it was in my opinion radical enough, and Dr. Agnew writes to me, December 27, 1882, "free incisions had been made, one *five* inches in length, opening up freely the post-peritoneal space of the lumbar region, in order to favor drainage, which was also assisted by means of drainage-tubes." What more the Professor would have I cannot imagine. He appears to find fault here for not doing enough, and later on we will find him blaming the attendants for doing too much.

After noting the metastatic inflammation of the parotid, which he says did not advance to a regular metastatic pyæmia, the Professor goes on to say that "The President did not die of pyæmia, but of a relatively small hemorrhage, after his powers had become exhausted by septic fever, by decubitus, by bronchial catarrh, and by hypostatic pneumonia. The hemorrhage followed a laceration of the splenic artery, which perhaps may have been caused by the ball, or by a splinter of bone; but probably it gradually formed later, under the influence of the ichorous degeneration acting upon a place contused by the ball, or against which a splinter of bone had been *squeezed* (*gequetschten Stelle*). Before the fatal hemorrhage, probably, a spurious aneurism had formed, which burst under the influence of the ichorous degeneration. If suppuration had not set in, the injury to the artery might not have produced any evil consequences."

H.: Why depreciate the hemorrhage by calling it relatively small? The record states that, besides some bloody fluid, the coagula which were gathered measured nearly a pint. Is it likely that a wound four-tenths of an inch long in so large an artery as the splenic would have healed spontaneously under any circumstances? Who of us here to-night, apparently in full health, would give much for his chance of life if he knew that there was suddenly thrown into his abdomen a pint of blood from an ulcerated splenic artery? Of the two, I would rather take my chance from a perforating gunshot wound of a vertebral body. Either would be enough to kill; our poor President had both conditions to contend with, and yet there are those who say he ought to have got well if he had had a fair chance.

I notice that the Professor does not say the blood was pushed out of the arteries after death by the embalmers' injection. He knows better than that!

To go on, E.: "It appears, therefore, that our colleagues on the other side of the ocean have not regarded our admonition as to the leading principle in the first treatment of gunshot wounds: 'Do no harm!' and the beautiful observations of Pirogoff, Klebs, Reyher, Bergmann, and others, upon the healing of the most serious gunshot injuries without suppuration, have made no impression upon them."

H.: That is fine! All we have to say is, that we have had a *few* gunshot wounds on this side of the water, and that we have made most beautiful observations upon them, and the outcome of those observations is that some get well and some do not.

E.: "The public, indeed, think that the ball is the most dangerous thing, and the soldier is happy when the ball which has been cut out of him is placed in his hand. The surgeon, however, should know that the ball itself in most cases does no harm. The real injury is what it has inflicted in its course, and what is superadded comes mostly from the fingers of the examiner."

H.: This is somewhat strongly put as to the last proposition, or else German fingers must be peculiar. With the other part I, and I think most of us, are in full accord, both as to practice and precept. I have written and taught in almost precisely the same words and to the same effect.

E.: "Practising American physicians seem, under the pressure of public opinion, to have assented to the proposition that much too *little* was done. But, according to my view, they did not do too little, *but much too much!*"

H.: It would be a fair logical sequence that, between these two extremes, just enough was done and no more!

Here is the climax and conclusion of this remarkable address:

E.: "If they had left the search for the ball entirely alone, and immediately after the injury treated it with *true antiseptic dressings*, the President probably might have been now alive, even as our Emperor, of whose numerous shot grains Langenbeck did not cut out a single one."

H.: Now, my dear Esmarch, is not this *ganz durchsichtig?* Is it not most uncommonly diaphanous? For one moment to compare the bird-shot peppering of the Emperor with the frightful, deadly wound of the President! Is it your regard for the "divinity" that "doth hedge a king" that makes you do this? As I write, I have before me German newspapers, and an extra of the day, containing full accounts of the attempt on the Emperor and the after-history. On the 2d of June, 1878, towards three o'clock in the afternoon, the Emperor, whilst taking a drive, was wounded by two discharges from a double-barrelled shot-gun, loaded with shot, and fired from the second-story window of house No. 18, Unter den Linden.

Many of the shot were warded off by the Emperor's helmet, of which he soon afterwards affectionately said, "How often, old helmet, hast thou done this duty for me! and now again thou hast protected my life." Nevertheless, there were wounds in the face and both arms, but none of any gravity whatever. A quarter of an hour after the outrage the Emperor took a cup of strong tea, and at half-past three Count Perponcher appeared upon the landing-place of the palace, and communicated to the assembled officers and cadets the facts that his Majesty had received three wounds from grains of shot—one upon the left temple over the eye, a second upon the cheek, and a third in the hand. He gave also to

the feverishly excited masses the comforting assurance that there was no danger to the life of the Emperor.

The royal patient kept his bed for a very short time, and on the 10th of June, 1878, the eighth day after the injury, at 9.30 o'clock in the evening, the following bulletin was issued by his medical attendants, Drs. von Lauer and von Langenbeck and Dr. Wilms:

"His Majesty the Emperor feels himself strengthened by a night's rest, and after the dressing was finished he left his bed for his arm-chair. Most of the wounds are healed. The arm, however, is still swollen, but is not so painful on being moved." The case went on without a drawback to complete recovery.

To compare this case with the President's! Full well you know, Dr. Esmarch, no one better, that if two mortals of the baser sort, wounded respectively as these two great men were, had been brought together into your hospital, that the one, after the requisite examination and dressing, and possibly after a few days' detention, would have been consigned to the care of the merest tyro in the out-ward; while the other would have claimed all of your knowledge and skill as a surgeon, and all of your sympathy as a man; and, although you may have appeared like impassive steel at his bedside, your heart would have bled at his imploring looks for that aid, which you were powerless to give, beyond mere temporary help; and some morning, coming and finding his place empty, you would have thanked God that relief had come for both of you at last.

When I said my discourse would be devoted to a few of the occurrences of the past year, I had no idea that one of them would take up so much of your time. The *great* event of the year, as important, if true, to surgery as to medicine, was the announcement that Koch, in Berlin, had discovered the origin of tubercle to be a bacillus, which he named the bacillus tuberculosis. This event also was heralded by cable and wires the world over. I had intended to give the discovery more than a passing notice, and I might dwell upon the excitement which it caused among all classes, scientific and lay, especially though in Germany.

No one has more graphically pictured the story than Dr. Formad, in his lecture before the County Medical Society, on October 18, 1882. The bacillus was discovered. The emperor saw it and fled. Virchow was driven back. We are told by an imperial order that in military hospitals phthisical patients were isolated. The community was in a ferment. Koch's conclusions are, however, not unchallenged, as the masterly labors of Formad prove.

More interesting and instructive reading than his lecture, I do not know. Formad admits the bacillus, but denies the claim for it as a cause, and right well, by experiment and reason, does he sustain his propositions.

And now there is another antagonist at hand. One whom some of us know well, Dr. H. D. Schmidt, a former close colleague of Dr. Leidy and myself, in this city, but now of New Orleans. When one sees that man, broken in health, lame, and with hands terribly crippled with rheumatism, through exposure in the field (for this was his condition on his last visit here), one is lost in wonder at his enthusiasm, and at the way in which he produces his beautiful work. He writes me, under date of October 20, 1882, in a tone of apology, for not having sent certain preparations for the Mütter Museum: "Just now I am very busy in preparing a paper on the bacillus tuberculosis of Koch, with which I have been occupied the last three months. I have made very extensive microscopic researches on this subject, during which I prepared and examined several hundred sections of tuberculous lung tissue taken from a dozen fresh cases, besides other fresh sections which I had on hand from my studies of the miliary tubercle during last fall and winter, and *I can say now that Koch's bacillus tuberculosis* appears to be nothing else but *a fat crystal* formed from the fat globules in the degenerating tubercular cells. I have found this pseudo-bacillus even in pathological neoplasms containing fattily degenerated cells. But my paper will tell you all about it." Here, then, is a man who has the temerity to deny the very existence of the bacillus which the emperor saw.

I would suggest whether it can possibly be the same thing that all of these men are looking at? Koch's and Formad's bacilli increase and multiply rapidly under nurture and cultivation. Schmidt's, if they are fat crystals (pseudo-bacilli), cannot surely do this.

And now I hear some specialist say, after the abrupt manner of Esmarch, "So *you* had intended to take up and discuss Koch's bacillus? What do you know about it?" My friend, did I say I *knew* anything about it? What do you *know?* I have a right to an opinion, have I not? I, who long ago put in a most touching appeal for maggots! Having noticed wounds healing kindly under masses of maggots, I reflected, that they were scavengers, eating only dead material, and so converting harming matter into harmless living substance. We have to get rid of them, it is true, because they will *persist* in getting into *wrong* places, and so give an infinite amount of trouble. Now are the plaguing micro-organisms of which we hear so much any more than consumers of dead material, serving (as we find them everywhere), a beneficent end, so long as they do not get into the *wrong* places? Molecular death is going on continuously in all living tissues. In the nice balance of perfect health, the results are removed so completely through the blood and lymph-channels (so beautifully described by Formad), and by other means, that there is no accumulation. When, however, disturbances arise, as inflammations, for example, from any cause, abundant *necrotic* products are the consequence, and these accumulate faster than they can be removed. Then come in the migratory micro-organisms. It is a question of food, and is consonant with what we know of the movements of hosts of higher animals, possibly also of plants, and sometimes of man himself. As these organisms get into the *wrong* places, they, accumulating with great rapidity, help to choke further and irritate what has already started on an evil course, and so they become secondary and very fruitful causes of disease. We may comprehend, from Formad's views, how scrofulous subjects with narrow lymph-channels, are more readily affected than others. *To my mind there is no positive proof as yet of the organisms being* SPECIFIC AND PRIMARY *in their operations.* I must say, if they are so, I do not comprehend how any of us are alive.

There is none the less reason to get rid of them, or to keep them out, in disease or injury. The *practice* of antisepticism does not require a theory of a fixed character to make it good, as Esmarch seems to think, nor need it be limited to one method. From the germicide sprays and liquids and the cumbersome details of the dressings of Lister, we may come to the use of simpler methods equally as effective.

It is truly astonishing how the medical, and the German medical mind especially, is impregnated with this subject. It really does seem to be a bacillary craze. I have before me as I write, the November, 1882, number of Volkman's *Klinische Vorträge*, containing an essay by Theodor Kocher, "Upon the Simplest Means of Obtaining the Healing of Wounds by Agglutination Without Drainage-tubes."

This writer discusses in a very thorough manner

the various articles used in antisepis. The merits of carbolic acid, iodoform, salicylic acid, and the chloride of zinc, are reviewed. His own purpose is to advocate the use of the subnitrate of bismuth (wismuth), which he does with great care and detail, and gives experiments and illustrative cases. It is not my intention to consider the matter here, but I hope to give this substance a trial. Kocher says that it is undisputed that a great number of wounds heal by Lister's carbolic antisepsis process, perfected by Volkman, but it is also certain that this often does not happen. "I have seen," he says, "colleagues who tenaciously hold to the spray, with all the attributes of the Lister-Volkman technique, here and there, have the most grave cases of infection, after complicated operations." Again, and here is a refinement to worry us! "As it is proved that with different forms of inflammation different micro-organisms come into action, that simple septic occurrences upon the wound and suppurations are not to be laid to the *same* coccobacteria, so it is to be inferred that by recent wounds and by already existing suppurations, the same antiseptic measures are not to be used."

What are we going to do about it? Different kinds of game, different kinds of ammunition. Buckshot for one, No. 12 for another. Before the surgeon can go to work, he must know the season, and what kind of germs are about, before he can select his germicide. The strict antiseptist is most skilled in strategy. He takes care of his base, and keeps the country behind him open. The theory must stand, and whatever mishap occurs is not due to it, but to incompetent officers, or failure in details.

It is the fashion now for writers and thinkers to express their ideas by epigrammatic generalizations, thus: Formad (agreeing with most recent pathologists)—"No inflammation, no tubercle." Koch—"No bacillus, no tubercle." I shall venture one which is much wider in its application, as it is not confined to tubercle alone, and according to the ideas I have expressed, it will meet the very great majority of cases, NO MICRONECROSIS, NO MICROMAGGOTS; *that is, food mostly in the shape of necrotic products, precedes the advent of the micro-organisms, however these may originate, whether animal or vegetable, and in disease these necrotic products first, plus the organisms second, play havoc with their environment.* I know these views will be regarded as obsolete by some, and was disinclined to express them, until I was delighted to find that Formad, and I think also Dr. Joseph Leidy—and if so, I wish no higher authority—essentially hold them. Thus, Formad says, "The presence of bacilli (so far as our present research goes) is *secondary*, and appears to *condition* the complete destruction of the tissue already diseased and infested by them, and this destruction is in direct proportion to the *quantity* of the organisms, which thus regulates the prognosis. The tubercular tissue seems to serve merely as a nidus for the growth of the bacillus."

What do I know about this, indeed? Please remember, friend specialist, I have put away my microscope for the present, and have turned dialectician. I am much further and much deeper than you! You, surface searcher, *go on* with your mucous membrane; I have reached the inner consciousness, and through it, sitting, like old Teufelsdreck, "alone with the stars," I may yet reveal a bacillus that will make you tremble.

No one can feel more relieved than I am at having passed safely through with the didactic. Now, do not despise me if I turn traitor at once, and return to my old love, the demonstrative. As soon as our President has dismissed us, the west room of the museum downstairs will be thrown open. There, among other objects of interest, you will find vertebra and vertebral bodies, and models illustrating the line of the President's wound; also photographs of it sent to me by Dr. Reyburn immediately after the autopsy. You will see splenic arteries, human and comparative. Judge whether, if wounded, a hemorrhage from one of them would be a trifle. You will also find Esmarch's portrait[1] and an Esmarch bandage—remember that this is a good thing, a very good thing; but how it can squeeze!—try it. I am sorry I have nothing to illustrate the wound of the Emperor. If it were reed-bird season, I could easily have had a boy up from the hospital, but reed-bird season is past.

Scientifically speaking, these objects are coarse compared to what is prepared for you in the east room of the library. There, under powerful miscroscopes, you will see Koch's bacillus by Formad, Schmidt's pseudobacillus, which I understand him to say is identical with Koch's. It does not appear to me to be so, but the special microscopists will have to settle this. You thus find that, even with them, seeing is not always believing, a point in favor of the didactic. The slides of Schmidt only arrived on Saturday evening, and have not been seen here before. You will also see live bacilli and other forms of bacteria. The microscopic exhibition will be almost entirely illustrative of the germs which are now considered to be such fruitful causes of disease, but which, as you have learned, some of us think are secondary.

Some of you of the laity may smile at scientific enthusiasm when you come to look at these minute rod-like lines, averaging, say the four-thousandth of an inch in length. But when you reflect what importance has been given to them by pathologists, and what influence they have already had, on German social life especially, you will understand the great interest taken in them. Some of the most noble and tender traits of humanity threaten to be undermined. The consumptive who has been heretofore lavishly loved and cared for, and nursed with tears and parted from with anguish, is to be isolated and shunned as a leper, if such doctrines as those of Koch prevail. Is it any wonder that some of us wish to look further before we adopt them?

NOTE.—There is authority enough for one in an address of this kind to allow the fancy some play, instead of keeping strictly down to the dry detail of science. In fact, the imagination in a right direction may be a great aid in developing scientific truth.

Tyndall has fully recognized Lucretius, and Goethe was prouder of his science than his poetry. Dr. J. Gibbons Hunt had under two microscopes at this meeting, what he called the "dance of life," and the "dance of death." Under one glass were swarms of bacteria (bacillus, and other varieties), fairly seething with life. Under the other were inorganic particles, which had been kept sealed up for two years, and yet they were in very active movement. A curious observation made by Dr. Hunt was, that these atoms were getting smaller and smaller as time went on. Whenever I see this life movement, and death in life, I think of the spirit lines in Faust. Goethe threw science and poetry into the same crucible, and subjecting it to the heat of his imagination, he poured out immortal ingots:

> In the sea of life, and the storm of deeds
> To and fro I rave,
> Entwine in commotion
> Birth and the grave.
> An eternal ocean,
> Webbed fabric of change,
> Life's glowing range.
> So on time's humming loom the warp I receive,
> And the living garments of Godhead I weave.

OPTICO-CILIARY NEUROTOMY, UNDER THE ANÆSTHETIC INFLUENCE OF THE BROMIDE OF ETHYL,

IN WHICH ETHYLIZATION AND OPERATION DID NOT OCCUPY MORE THAN TWO MINUTES.

BY JULIAN J. CHISOLM, M.D.,
PROFESSOR OF EYE AND EAR SURGERY IN THE UNIVERSITY OF MARYLAND, BALTIMORE.

FOR many months I have been using the bromide of ethyl daily for all operations which I could speedily complete, and, having experimented with this new agent over three hundred times in the past year, I am beginning to feel that I know how to use it and what to expect from it. I have found that its action is so very evanescent that it can never take the place of chloroform or sulphuric ether for any surgical operation which requires some time for its performance; but for all quick work, which can be done in one or two minutes, the use of this anæsthetic agent leaves nothing to be desired. For this purpose it is very far superior to any other known anæsthetic. As the result of my every-day experience—for I use this agent now in every case in which pain enters as a factor—a drachm of the bromide of ethyl, when properly used, will put any patient into deep narcosis in less than a minute by the watch. Some of my patients have been narcotized fully in twenty-two seconds. This deep anæsthetic sleep will not last more than from one to two minutes. From this narcosis the patient awakes suddenly, as if from ordinary sleep, with brain as clear as before the inhalation, and with neither nausea, headache, nor heaviness of any kind. I find the use of this anæsthetic a great saving of time in my office surgical practice, and have often had patients ethylized, operated upon, restored to consciousness, and leaving my office, feeling perfectly well, within ten minutes from the time they entered the office door.

These really magical effects must be obtained from the first inhalation, and what I will call primary anæsthesia. Should the operation be protracted and a second, and even a third dose of the bromide of ethyl be inhaled, then I find nausea, vomiting, and heaviness in all respects, as if chloroform or ether had been used. Under this repetition the bromide of ethyl loses all of its advantages. To use it successfully and take advantage of this evanescent narcosis, one must be methodical and have every preparation for an operation made in advance. Should the surgeon have to seek instruments, even from a contiguous table, he may find the patient wide awake on his return. The report of the following case is constantly repeated in my daily experience with the beautiful working of this wonderful agent.

Mr. C., aged 55, consulted me with a letter from his family physician, who lives 200 miles from Baltimore. For five months he has from time to time suffered fearfully with his head and his left eye, the sight of which he has entirely lost, no appreciation of light even remaining. From the severity of his suffering often with nausea, the case was called a cerebral lesion, and the most serious results feared. I found the case one of acute glaucoma not recognized, and with all of the distressing symptoms secondary to the disease in the eye. Had an iridectomy been performed five months since, possibly the sight would have been saved and all of the suffering prevented. Now either the eyeball had to be sacrificed to end the frequent attacks of pain, or a division of the eye nerves made as they enter the back of the eyeball. This latter operation was recommended to him and he accepted it.

The patient was put on the table with the intent of being chloroformed, but thinking that I could manipulate rapidly enough to give him the benefit of the bromide narcosis, I determined upon the use of this anæsthetic, which I had just administered to a lady for the removal of a tarsal cyst.

The instruments necessary for the operation were all placed on the table in the order which they were to be used. The patient was told to take full breath when the inhaler was placed over his face, and was made to practise full inspiration in advance. A towel, between the folds of which paper had been put, was made up into a small nearly air-tight cone. Into this was poured about a drachm of the bromide of ethyl and immediately inverted over the nose and mouth of the patient. Notwithstanding the stifling sensation from this saturated atmosphere of ethyl vapor, he commenced full inspirations. By the time he had taken the eighth inspiration I found his conjunctiva insensible to reflex action. He had not been inhaling the ethyl more than thirty seconds when deep narcosis was fully established.

The operation was at once commenced. The lids having been separated by the stop-wire speculum, an incision was made in the conjunctiva on a line with the lower border of the inner rectus muscle, extending from the edge of the cornea to the caruncula. A second clip with the scissors divided the fascia and made a free opening between the inner and lower recti muscles. Into this opening the heavy curved scissors was introduced. Using it as a probe, the resisting optic nerve was soon found. Drawing outward the point of the scissors, the blades were widely opened, the optic and all contiguous ciliary nerves were caught between them and severed. A second opening and closing of the scissors, then again using it as an explorer, its unrestrained movements in the muscular cone behind the eye showed that all the structures entering the back of the eye-ball including ciliary nerve, arteries, and veins, had been divided. With the withdrawal of the scissors blood welled up from the wound in the conjunctiva. The speculum was immediately removed, a firm cotton compress applied and tightly secured by a bandage, and the operation was completed. It took much less time to manipulate the instruments than it has taken me to describe the process. From the beginning of the ethylization to the tying-up of the eye the whole operation had not occupied a minute and a half. During this period the patient had been sleeping undisturbed, with a strong pulse, quiet respiration,

and a good color of face. I had hardly laid down his head, after securing the compress, when he awoke, and was very much surprised to find his head bandaged. He got off from the table at once and within three minutes from the time that the ethylization was commenced he was walking with a firm tread, unassisted, from the operating-room of the hospital to the contiguous ward, from which he seemed to have just come out.

To ethylize efficiently, a saturated vapor must be used, and the inhaler *must not be taken from the patient's face once the apparatus has been put over the nose and mouth.* Hold it down firmly for a very few inspirations, and your patient will be in condition to have any painful manipulation carried out.

In twenty-two seconds and with six inspirations I have established deep narcosis.

In no one case of the three hundred has it required more than 60 seconds.

In no case did deep narcosis from a primary inhalation exceed two minutes in duration.

In the midst of a large surgical practice, as a specialist in eye diseases, I find constant daily use for the *deep* and *very evanescent* narcosis of the bromide of ethyl. I use it for the passing of nasal probes, splitting of the canaliculi, scraping out the contents of tarsal cysts, opening lachyrmal abscesses, cutting defective muscles in squint, removing the elliptical piece of skin of the lid in ptosis or entropion, performing iridectomies for glaucoma, or for the making of artificial pupils, and, as in the case just reported, for optico-ciliary neurotomy.

It needs confidence in the safety of the anæsthetic to push it in its concentrated form; and I am convinced that in no other way can the best effects of a primary anæsthetic be produced.

It also requires quick movements on the part of the surgeon to complete the operation before the narcosis passes off. I have frequently performed the operation of squint before the medical class at the University of Maryland clinic in less than sixty seconds, this period including the whole time occupied from the beginning of the ethylization to the completion of the tenotomy. In all of the special operations which I have enumerated, the operative procedure must have been completed within two minutes to have protected the patient from all knowledge of what had been done, so that he should feel nothing of the painful manipulation.

THE MICROCOCCUS OF GONORRHŒAL PUS—INFECTIVE VIRULENCE NOT DUE TO THE PRESENCE OF THIS PARASITIC MICRO-ORGANISM.

BY GEO. M. STERNBERG, M.D.,
SURGEON, U. S. A.

(*Concluded from p. 70.*)

REMARKS UPON MORPHOLOGY, DISTRIBUTION, ETC.

THE method which I have found most satisfactory and convenient for demonstrating the presence of micro-organisms in blood, pus, or culture-fluids, is the following. A small quantity of material is spread out upon the surface of a perfectly clean glass cover, so as to form a uniform and extremely thin layer; this may be conveniently done with the end of a clean glass slide. This is allowed to dry, spontaneously or by the aid of gentle heat, and is then stained with one of the aniline colors. Methyl violet is the staining reagent which I most frequently employ; a very good solution for this purpose is the common violet ink, for sale at every stationer's.

A drop of this, applied to the thin glass cover, will stain the micro-organisms attached to it in a very brief time. A few seconds will usually be sufficient. The staining fluid is then quickly washed away in distilled water, and the specimen is ready for examination under the microscope.

A little gonorrhœal pus, taken from the meatus urinarius of a recent case, treated in this way presents the appearence shown in Figure 1. The am-

FIG. 1.

plification in this and in the other figures illustrating the present paper, is one thousand diameters.

The pus corpuscles adherent to the thin glass cover are flattened, and present a more or less irregular outline, as the result of the manipulation—spreading and drying—to which they have been subjected. The nuclei—so called—are deeply stained, and appear as violet-colored masses, often elongated, and presenting the aspect of a protoplasmic mass undergoing division.

That these masses are composed of living protoplasm, and the unstained portions of the pus corpuscles of "formed material" (Beale), seems probable from the fact that they are stained by carmine and the aniline colors. But it is difficult to accept the statement of the author named, that "The white-blood corpuscle is one thing; the pus corpuscle a very different thing,"[1] after having examined a specimen of pus, and a drop of blood from the finger, by the method above described. The red corpuscles lose their color, and can scarcely be seen after being subjected to this treatment; but the white corpuscles become conspicuous on account of their deeply stained nuclei, and resemble exactly pus corpuscles treated in the same manner.

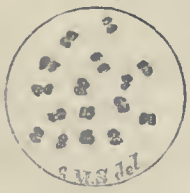
In addition to the stained nuclei, a certain number of the pus corpuscles are seen to contain small spherical or slightly oval bodies, stained even more

[1] The Microscope in Medicine. 4th ed. J. & A. Churchhill London, p. 304.

deeply than the nuclei, grouped in pairs, in fours, and, rarely, in chains of three or four. A majority of the pus corpuscles are free from these parasitic micrococci; some contain them in small numbers as in the centre of the field in Fig. 1; and occasionally a corpuscle is completely filled with them, as shown on the left of the same figure.

A little pus containing these micrococci introduced at the moment of its escape from the meatus into a flask containing a suitable culture-fluid, sterilized, and subsequently placed in the culture-oven for twenty-four hours, or less, at 100° Fahrenheit, causes this fluid, which was previously transparent, to assume a milky appearance. Microscopical examination shows that this is due to the presence of micrococci, joined mostly in pairs, as shown in Fig. 2, which pervade the fluid to such an extent that the smallest drop contains a multitude of them.

FIG. 2.



The fact that they are joined in pairs and that they are found throughout the culture-fluid, shows that they are in active growth and are multiplying rapidly by spontaneous fission.

Later, when they have exhausted the material in the limited quantity of culture-fluid required for their nutrition, their active life ceases and they sink to the bottom of the flask, where they are seen *en masse* as a white deposit, while the supernatant fluid is again transparent. The same phenomena occur when, instead of pus containing *Micrococcus ureæ*, we use a drop of blood from a septicæmic rabbit, just dead, to inoculate our culture-fluid. But in the latter case, instead of assuming a milky appearance during the active growth of the septic micrococcus, which now pervades our culture fluid, we have an *opalescence* sufficiently distinct, but presenting to the eye a recognizable difference when compared with the other. This difference doubtless depends upon the fact that the septic micrococcus has more nearly the same refractive index as the culture-fluid in which it is contained, or, in other words, is more transparent than *Micrococcus ureæ*.

A microscopical examination shows very decided morphological differences in the two organisms, which, being constant, furnish specific characters as definite as are presented by many plants much higher in the scale. The septic micrococcus, as it appears when in active growth in a culture-fluid, is seen in Fig. 3.

It is impossible in a woodcut to represent the aureola of transparent material which is a marked character of this micrococcus. This is well shown in the photo-micrograph illustrating my paper on septicæmia (*loc. cit.*) This aureola is more pronounced in the blood, and in cultures made in blood-serum than in those in *rabbit-bouillon*, which is the fluid in which I have commonly cultivated this organism.

FIG. 3.

The most important distinguishing character of the two species of *micrococcus* under consideration is found in the fact that one—the septic—divides in one direction only, thus forming a linear series of two or more oval elements attached to each other in the direction of their long diameter; while the other commonly divides in two directions, the elements being arranged in pairs, as seen in Fig. 2, or in groups of four, as shown in Figs. 1 and 5, resulting from the transverse division of each of the oval elements, arranged side by side, constituting a primary pair.

These micrococci are not so easily distinguished, the one from the other, when, having exhausted the nutritive material necessary for their active development, they sink to the bottom of the culture-flask.

Under these circumstances, microscopical examination commonly shows little groups of spherical bodies, having about the same dimensions, and which resemble each other so closely that, as in the case of the seeds of higher plants (*e. g.*, turnip and cabbage), an expert might easily be at fault in attempting to distinguish one from the other. But by the experiment of planting in proper soil, the fact that essential differences exist is readily established in both cases. And, as in the higher plants, it may be shown that, *after the material required for the development of one micrococcus has been exhausted in a certain quantity of culture-fluid, the other species will develop abundantly in the same fluid upon the introduction of seed*-micrococci. This fact I have recently demonstrated experimentally.

My observations show that the microscopic plants under consideration *vary considerably as to size in the same culture-fluid, and in different media present marked differences in this respect*, due to nature and amount of pabulum, temperature, etc., in short, to conditions in the environment, and favorable or otherwise to the growth of the plant.

These differences, when we consider the comparative size, are as well marked as in higher plants, and give ample scope for the development of varieties and species, under the operation of the laws of "natural selection."

In Figs. 4 and 5, this difference in size is very apparent. In Fig. 3 we have *Micrococcus ureæ*, from urine which has undergone alkaline fermentation; and in Fig. 4, the same organism derived from gonorrhœal pus (third culture).

A mere inspection of these figures might lead to

the conviction that we have here two different micro-organisms; but extended observations and the experiments already detailed, have convinced me that such is not the case, and that, within certain limits, differences in size cannot be accepted as specific characters among the micrococci, any more than in the case of turnips and cabbages.

FIG. 4.

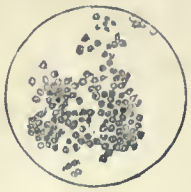


FIG. 5.

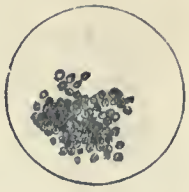
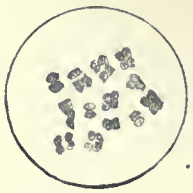


By the use of high powers and staining reagents, these differences become very apparent, and micrococci from the same source and in the same field of view may differ in diameter as much as one-half. Measurements, therefore, have only a comparative value and it is easy to understand how Pasteur has given the diameter of *M. ureæ* as 1.5 μ, while Cohn has placed it at 1.2 to 2 μ.[1]

The limits of variation are even wider than stated by the writer last named. In Fig. 6 we have what

FIG. 6.



I believe to be the same micrococcus from a different source, viz., from a culture in acid malt-extract inoculated with human saliva.

This micrococcus is found very constantly in the buccal secretions, where it is often seen in groups attached to or parasitic within the shed epithelial cells. I have also frequently observed it in the sputa of tuberculous patients, and, indeed, my studies lead me to believe that it is one of the most abundant and widely distributed of micro-organisms. That it does not, under ordinary circumstances, multiply in the blood or tissues of a living animal, and consequently is not a pathogenetic species is shown by the experiments already recorded, and by the fact that when human saliva containing it, as well as many other micro-organisms, is injected beneath the skin of a rabbit, it is not found associated with the septic micrococcus in the blood of the animal examined immediately after death. This experiment, therefore, affords a ready means of obtaining a pure culture of the septic micrococcus, while from gonorrhœal pus we may obtain an unadulterated stock of *Micrococcus ureæ*, the associated micro-organisms commonly found in normal saliva, or upon the mucous membrane of the healthy urethra, being excluded in one case by cultivation in the body of a living animal, and in the other by some peculiarity of the pus which favors the development of this particular organism.

The photo-micrograph from which Fig. 6 is drawn was used to illustrate my paper upon "Bacterial Organisms Commonly Found upon Exposed Mucous Surfaces," etc. (*loc. cit.*), and I then described it under the generic name of "*sarcina*," with an interrogation point as to the species. This determination was made in accordance with the definition given in Magnew's work ("The Bacteria," *loc. cit.*), which is as follows: "The *sarcina* can be considered as bacteria in which the division occurs by two perpendicular partitions, in such manner that multiplication takes place in two directions."

I have already stated that this mode of division occurs in the micrococcus of gonorrhœal pus, which I have shown to be identical with *M. ureæ* Cohn. This organism may also multiply by division in one direction, only so as to form chaplets of five or six elements. It is evident then that the character referred to—division in two directions—does not belong exclusively to *sarcina*, or that Cohn was mistaken in referring the organism in question to *micrococcus*, to which genus he gives the following characters:

"Cells colorless, or scarcely colored, very small, globular or oval, forming by transverse division filaments of two or several articles, in form of chaplet, or united in cellular families, or in gelatinous masses, all deprived of movement."

INFLUENCE OF TEMPERATURE, ETC.

As the result of a considerable number of experiments I have fixed the thermal death-point of these two species of *micrococcus* at 140° Fahr., the time of exposure being ten minutes. A lower temperature and longer exposure is, however, destructive of vitality. Thus *M. ureæ* failed to multiply in a sterlized culture-fluid after being exposed to a temperature of 130° for thirty minutes in one experiment, and to the same temperature for fifteen minutes in a second. But both species survived a temperature of 130° for ten minutes (experiment several times repeated, with the same result).

These results correspond very nearly with those obtained by other observers who have experimented with different micro-organisms *provided these were in an active growing condition, and no spores were present.*

Thus Cohn found that *Bacillus nuptilis* multiplies freely at 45° to 50° C. (113° to 122° Fah.), while at a temperature of 50° to 55° all reproduction and development cease, and the filaments are killed.[1]

Chauveau, in a recent communication to the French Academy upon "Attenuation of Virus by Heat (method of Toussaint)," says that nine or ten minutes' exposure to a temperature of 54° C. (129.2° Fah.) is sufficient to kill completely the bacilli in anthrax blood.[2]

[1] The Bacteria, *loc. cit.*

[2] C. R. Ac. des Sciences, June 26, 1882, t. xciv. p. 1694.

Pasteur, as the result of numerous experiments upon "diseased ferments"—bacterial organisms—which injure the quality of beer, found that "alcoholic ferments heated in beer can endure a temperature of 55° C. (131° F.) without losing the power of germination; but the action is rendered somewhat slower and more difficult. Diseased ferments, however, existing in the same medium, perish at this temperature, as they do in the case of wine."[1]

The author last named has shown that the reaction of the fluid in which micro-organisms are contained influences greatly the thermal death-point of these organisms, and that this is considerably less in an acid than in an alkaline medium.

From 98° to 100° Fah. is an extremely favorable temperature for the active growth of both of the species of *micrococcus* which are under special consideration in the present paper. The limits above and below this point at which active growth is possible I have not found time to determine, but my observations lead me to believe that the septic micrococcus is a more delicate plant than the other, and that comparatively slight variations as regards temperature and composition of nutritive medium may arrest its development. My efforts to cultivate this micrococcus for successive generations in beef tea have not been successful, while a *bouillon* made from the flesh of the rabbit furnishes a nutritive fluid in which it multiplies abundantly. I first resorted to the use of this culture-fluid upon a hint furnished by Pasteur in the report of his experiments relating to the etiology of fowl-cholera. A *bouillon* made from the flesh of fowls was found to be the most favorable medium in which to cultivate the micrococcus peculiar to this disease. This sensitiveness as to the temperature and composition of the nutritive media in which they are placed seems to be a common characteristic of pathogenetic micro-organisms, and, doubtless, is the main reason for the marked differences as regards susceptibility to their pathogenetic action observed among animals of different species.

The same phenomenon is a matter of common observation among the parasitic fungi which infest different plants, producing the diseases known as smut, rust, mildew, etc. We may even have a marked difference as regards susceptibility to the attacks of a certain fungus among varieties produced by cultivation, which originated from the same stock.

In the case of the septic micrococcus this sensitiveness as to composition of medium has, nevertheless, rather wide limits, for I have been able to cultivate it both in acid and in alkaline *bouillon* (from rabbit), and also in acid urine.

Micrococcus ureæ seems to be a hardy plant which thrives in a variety of organic liquids, and is not very sensitive as regards temperature or the presence of various salts in considerable quantity, which, *à priori*, might have been supposed to be prejudicial to its development. I have found, however, that a temperature of 60° Fah. is not sufficient to promote its active growth, and that sterilized urine to which a culture fluid containing this micrococcus has been added, remains acid and transparent for a considerable time at this temperature.

The writer has for some time past been engaged in an experimental study of the action of various germicides upon these micrococci and upon other micro-organisms, but this is an investigation involving a large amount of labor, and some time will be required for its completion.

In conclusion I beg leave to call the attention of any who may be inclined to under-estimate the value of studies of this nature to the fact that, aside from questions of professional interest relating to the *rôle* of micro-organisms in the etiology of infectious diseases, and the best methods of combating pathogenetic bacteria within or without the living body, biological problems of great interest are best approached by studying the vital (chemical?) reactions of these extremely minute unicellular organisms, which offer the simplest possible conditions for such studies, and which may be manipulated by the biologist by modern scientific methods with as much certainty as regards definite and constant results, the conditions being the same, as is possible for the chemist in his operations with non-living material.

Note.—Since the above was written, I have stumbled upon the following in *The Medical Record*, of Sept. 23, p. 359.

"*The Gonococcus*—Neisser in Breslau, who in 1879 published the discovery of a micrococcus which was to be found in every case of specific blennorrhœa, either of urethra or of eye, but nowhere else, has recently recorded his conviction that this "gonococcus," as he calls it, is the specific agent in producing the disease; and quotes Aufrecht, Ehrlich, and Griffkey, the opthalmologists Leber, Sattler, and Hirschberg in support of his statements. But until recently the *experimentum crucis*—successful inoculation of the micrococci—had never been performed from the simple fact that animals are not susceptible to the gonorrhœal contagion, and human subjects have always preferred to acquire theirs in another way. Recently, however, Bokai, in Pesth, was so fortunate as to find six philanthropic students who placed their urethras at the disposal of science. With the 'gonococci' which Bokai had cultivated artificially from gonorrhœal discharge, the six were inoculated; and three had the satisfaction of exhibiting a week later a classical gonorrhœa. For one familiar with natural history of medical students, the experiment would have been far more convincing if the dauntless three had been kept in solitary confinement for a week before and after the inoculation."—*W. T. Belfield, in Chicago Medical Journal and Examiner.*

POST SCRIPTUM.—*Experiment No. 15* (Oct. 5, 1882): A pure culture of the micrococcus from gonorrhœal pus (the thirtieth culture (?) or above) was introduced into the urethræ of two healthy men by means of pledgets of cotton wool, soaked in the fluid, which were left *in situ* for fifteen mintes.

Result entirely negative.

MEDICAL PROGRESS.

Bacteria and their Presence in Syphilitic Secretions.—Dr. Morison, of Baltimore, who is at present working in Prof. Neumann's laboratory in Vienna, has published in the January number of the *Maryland Medical Journal* an account of the pathogenetic organisms found in the lesions of syphilis and of the non-specific venereal ulcers. The organisms supposed to be specific for syphilis were found in sections of the hard chancre, and in numerous syphilitic skin affections, always at the seat of disease and never in the general blood circulation; in this they agree with the bacilli of tuberculosis and of lepra. They are only visible when stained, and the method of staining is rather complicated; but doubtless this method will be so modified in the course of time as to be much simpler, as Koch's original method for staining the bacillus tuberculosis was subsequently modified by Ehrlich. The bacilli described by Dr. M., are short cylindrical rods. In the lithograph we notice that some of them are slightly bent, and have in places the appearance of lying together in pairs; in point of size we should say, judging from the plate, drawn under a power of × 850, that they are somewhat smaller than tubercle bacilli. The bacilli found in non-specific ulcers (chancroids) are longer than the syphilitic, are extremely thin and in the plate represented as curved; from which we would suppose that they belong rather to the group of spirochæte, and not to the true bacilli. We must disagree with the author when he says that they closely resemble the bacillus anthracis. The number of germs discovered by various observers in syphilis are many, most of them being found in the blood as well as at the seat of the lesion. No special method of staining was used to demonstrate them and subsequent investigation failed to confirm them. By this last discovery of Morison's, we see that only by the employment of the most complicated methods of staining, and the use of the now indispensable Abbey's illuminator and oil immersion glasses, can they be seen. At best, however, we fear that, although the bacilli may be cultivated with success, strict proof of their causal connection with syphilis will always be wanting, owing to the impossibility of infecting lower animals with the disease. The experiments which the author mentions —those of Martineau and Hamonic on young pigs—are so utterly at variance with former experiments, that they must be confirmed. We can only hope that this latest bacillus in the field will not share the same fate at the hands of the great New Orleans microspopists as did the bacillus lepræ and b. tuberculosis.

Elongation of Nerves.—M. Trélat, at the meeting of the Société de Chirurgie held December 13th, read a report on a work of M. Badal, of Bordeaux, on this subject. Recently M. Badal has stretched the external nasal nerve in three cases of circum-orbital neuralgia, and in all three cases a cure resulted. The operation is very readily performed by making an incision near the angle of the eye, and exposing the nerve between the tendon of the orbicularis and the great oblique muscle.—*Gaz. Méd. de Paris*, December 23, 1882.

Simple Method for Detecting Tubercle-bacilli in Sputa.—The following plan is followed in the pathological laboratory of Prof. Rindfleisch, in Würzburg. A portion of the sputum is pressed between two cover-glasses, which are then separated and dried in the air. A staining fluid is prepared according to Ehrlich's formula; the cover slip is then passed three times rapidly through the flame of a spirit-lamp, the sputa being on the upper side, and then floated in the staining fluid, which is contained in a watch glass, and the latter held over the flame until the fluid commences to vaporize. The cover-slip is then removed, washed in a stream of water, and laid in absolute alcohol which has been slightly acidulated with nitric acid, when the color will be removed in about ten seconds. The slip is then taken out of the alcohol, again washed in water, dried, and mounted in balsam.—*Wiener Med. Presse*, December 24, 1882.

Jequiriti in the Treatment of Granulation of the Conjunctiva.—At the meeting of the Société de Chirurgie held December 13th, M. Terrier read a report on a memoir of M. José Cardosa, of Rio Janeiro, on the employment of this drug. The jequiriti is a leguminose plant; an infusion made of the seeds and employed as a lotion to the conjunctiva in cases of granulations, sets up an acute inflammation, and may, in large doses, even cause severe accidents. M. de Wecker has employed the preparation with satisfactory results, while in the only case in which M. Terrier employed it an intense purulent conjunctivitis was set up, which was cured without the granulations undergoing the least improvement. So while in certain cases it may be used with success, it should always be employed with caution. M. Desprès maintained that the only justifiable treatment of this disease was excision of the granulations when chronic, while, when inflammatory, they may be cured by cauterization with sulphate of zinc or nitrate of silver.—*Gaz. Méd. de Paris*, December 23, 1882

Dislocation of the Liver.—At a recent meeting of the Society of German Physicians in Prague, Prof. Pribram reported a case in which, on account of a pyopneumothorax of the right side, the diaphragm and liver were displaced downwards. The liver had entirely left its normal situation in the right hypochondrium, and was so twisted that, while the left lobe was only slightly displaced downwards, the remainder of the liver lay with its long axis vertical, and its normally inferior surface looking to the left. As a consequence of this dislocation, the transverse colon was bent on itself, and displaced downwards nearly as far as the symphyses. This condition had been recognized during life, and caused a certain amount of obstruction during life, particularly to the escape of blood from hemorrhage from a large tubercular ulcer in the duodenum.—*Wiener Med. Presse*, December 3, 1882.

Treatment of Hydrocele.—The following is the treatment of hydrocele employed by Dr. Cattaneo in the hospitals at Pavia:

1. Puncture of the hydrocele with a capillary trocar of an aspirator, and evacuation of the fluid.

2. Injection of a solution of hydrate of chloral in quantity proportionate to the volume of the hydrocele and age of the patient: one to two grms. of chloral for children, four grams. for adults, and occasionally more in old men. The solution is made by dissolving equal parts of chloral in cold distilled water.

3. Cold applications to overcome the pain produced by the injection.

4. The injection is repeated if the absorption occurs too slowly.

The patients are kept in bed during this treatment and wear a suspensory bandage for some time afterwards. It is claimed by Dr. Lampagnani, who reports this treatment, that the effusion has not returned in any one of seventeen cases so operated on, nor have there been any complications in any case.—*Journ. de Méd. de Paris*, December 9, 1882.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JANUARY 27, 1883.

NATIONAL PUBLIC HEALTH LEGISLATION.

DURING the present session of Congress but three bills have been introduced which have any special relation to sanitary matters. These are: 1, a bill introduced by Mr. Hardenbergh in the House, Dec. 19 (H. R. 7,085), "To prevent the importation of adulterated teas;" 2, a bill introduced in the Senate by Mr. Harris (S. 2,259), "To repeal the tenth section of the Act approved June second, eighteen hundred and seventy-nine," etc.; and, 3, a bill introduced in the Senate by Mr. Conger (S. 2,284), and in the House by Mr. Rich (H. R. 7,121), "To provide for the sanitary inspection of immigrants."

We shall probably have occasion to refer to Mr. Hardenbergh's bill hereafter, in speaking of adulteration of food and drugs legislation; at present we shall only consider the bills of Senators Harris and Conger. The bill of Senator Harris repeals the tenth section of the Quarantine Act of June 2, 1879, which reads as follows, "Sec. 10. This Act shall not continue in force for a longer period than four years from the date of its approval;" and also repeals the clause of the appropriation bill of last year which restricted the operations of the Board to cholera, yellow fever, and smallpox. It also provides that, of the unexpended balance remaining to the credit of appropriations made for the National Board of Health, $124,000 shall be available for the use of the Board during the next fiscal year, and that an additional sum of $100,000 from the unexpended balance of moneys to be used only in cases of epidemic shall in like manner be available for the same purpose during the coming year.

Senator Conger's bill provides for an appropriation of $25,000 "To enable the National Board of Health to coöperate with State and local boards of health, and local quarantines; and to continue during the remainder of the current fiscal year the sanitary inspection of immigrants, for the purpose of preventing the introduction of smallpox and other contagious diseases into the United States, and their spread from one State to another." It will be seen that this last bill simply provides funds to carry on the inspection work until the 30th of June, the appropriation made last year being insufficient for this purpose. So far as we can learn, there is little probability of the passage of either of these bills in a separate form by the present Congress, owing to the fact that this is the short session, and that there is a vast amount of legislation pending in which members of Congress are much more actively interested than they are in health matters. It is, however, possible, that the substance of one or both of these bills may be incorporated as a clause in the appropriation bill, although the hostility of the chairman and other members of the House committee of appropriations to the National Board is such, that any such clause must probably be put in as an amendment, in the face of their opposition.

Since the publication of the editorial on the National Board of Health in our issue for Nov. 11, 1882, page 546, we have received an unofficial letter from Dr. Hamilton, Surgeon-General of the Marine-Hospital Service, in which he expresses a general concurrence with our views as to the essential function of a national health organization, and incloses the following extract from a communication made by him to a member of the Public Health Committee of the House, dated March 6, 1882:

"It may be asked what there would be left for the board of health to do [after the loss of the national quarantine]? In answer, it is only necessary to point out the scores of questions yet undecided as to the causation and prevention of diseases and epidemics, as well as the consideration of the different problems connected with public and domestic hygiene about which a board of health might be reasonably supposed to concern itself. The dignity and usefulness of the Smithsonian Institution have never yet been impaired by the fact of its complete severance from executive work, and I am sure that the board of health would grow in popular favor and largely increase its usefulness by a slight change in its constitution, a more proper direction of its work, and its complete disconnection with executive work for which it has evidently neither adaptability nor facilities."

In his letter to this journal, Dr. Hamilton still further defines his position in the following words:

"I have and shall continue to oppose the transfer of sick sailors to the National Board under the guise of a national quarantine, but I do not oppose the Board or its legitimate work. The work of this service is the health and hygienic interests of sailors and boatmen, but if we are to have a *national* quarantine at all, I claim that the Treasury Department, which not only has *medical* officers, but the customs officers and coast guard at its disposal as well, is the proper department. . . . Now it is more reasonable that the commercial interests shall be consulted in the disposition of this matter than that a few office holding 'sanitarians' should disturb the ordinary channels of business for the sake of bestowing a few offices upon their favorites. Now if offices are to be created *de novo*, we do not concede that the National Board of Health has any better facilities for procuring them, or that their system of appointment affords any better guarantee that they shall be competent than the method now pursued by the other branches of the public medical service; on the contrary, while the Board does not examine its appointees, the Army, Navy, and Marine-Hospital Service require theirs to pass a rigid professional examination."

We have quoted thus fully from Dr. Hamilton, because we desire to have his views fully and fairly represented. It is much to be regretted that there is a certain degree of hostility existing between the Marine-Hospital Service and the National Board, and the more so since this hostility appears to us to be almost entirely groundless. We cannot understand, on the one hand, why the National Board should object to the transfer of all quarantine executive work to the Treasury Department, nor, on the other hand, how it can in any way interfere with the work of the Marine-Hospital Service to have the work of aiding State and local boards in quarantine work performed through the National Board, as at present.

Dr. Hamilton is rather unjust in his sneer at sanitarians and their motives, as we think he would admit upon reflection, but it must be remembered that his letter was written just after the meeting of the American Public Health Association, where some of the sanitarians were disposed to speak harshly of his services, and it will be observed that he disclaims all hostility to the Board itself. Since our last editorial on the National Board, Dr. Folsom and Mr. Phillips, the Solicitor-General, have withdrawn from it, and some criticism has been made of the remaining members, in that they have not also resigned, and have appealed to physicians and sanitarians to influence Congress in their behalf.

It seems to us, however, that the question as to propriety of resignation is purely a matter of individual view as to what is becoming and to the best interests of the Board under the circumstances; and there is plenty to be said on both sides. We can see no impropriety in their having appealed to physicians and sanitarians; there is, in fact, no other class to whom they can properly appeal for a competent judgment as to whether they have done well or ill. The question must be settled in some way very soon, for if Congress at its present session does nothing, the present Quarantine Act lapses on the second of June next, and the Board remains under the constituting act alone. Whether the lapsing of the present quarantine act revives the one which preceded and was annulled by it, and which put the matter in charge of the Marine-Hospital Service, is a legal question, not yet decided; but probably it does not.

As indicated in our previous editorial, this question of quarantine, and who is to act as almoner for the United States with regard to it, seem to us questions of secondary importance as compared with the question whether we are to have a National Health Commission, to carry out investigations into the etiology of disease, and furnish authoritative and reliable advice and information when they are required. It is probably impossible during the present session of Congress to obtain legislation which will put the National Board of Health upon a proper footing, but, at all events, an effort should be made to prevent its abolition, or the leaving it entirely without means or duties.

OSSEOUS AND ARTICULAR LESIONS IN LOCOMOTOR ATAXIA.

THE advantages which the wide experience of a large hospital afford in the study of disease are especially well seen in the accumulation of many cases of comparatively rare disorders, or of unusual results of the more common. Such cases gravitate naturally toward these centres. And when to the great hospital is added a man of uncommon force and acumen like Charcot, this centripetal force is still more marked. Many of us have seen isolated cases of fractures and other bony lesions in ataxia, but at la Salpêtrière Charcot has had them by the score, and his accumulated facts are so much the more valuable.

In a recent number of the *Archives de Neurologie*, FÉRÉ presents an elaborate description of the specimens from eight cases not previously related, collected by Charcot since 1876, besides others which have been given to the Musée Dupuytren, the Hunterian, St. Thomas' Hospital, the Manchester, and other museums. Eighteen excellent woodcuts illustrate the paper.

One of these patients furnished the first complete ataxic skeleton ever examined, and with the result not only of verifying numerous lesions of bones and

joints recognized during life, but of discovering a fracture of the right ilium and left fibula, which had passed unperceived. For the first time also an arthropathy of the temporo-maxillary articulation has been observed *post-mortem*. In this series the hip-joint and the shoulder were chiefly affected, especially the first. The head of the femur and humerus had frequently disappeared, and in some cases the entire upper end was gone, leaving only a conical stump-like extremity, rough, porous, eroded, and corresponding to an equally diseased cotyloid cavity. Dislocation was not uncommon, and a striking full-length figure of a woman is given, in whom the end of the left humerus presented under the clavicle, and the upper end of the left tibia and fibula were dislocated backwards and upwards four inches above the condyles of the femur, stretching but not rupturing the crucial ligaments.

The now well-known frequency of fractures in ataxics finds several illustrations here. Some are re united firmly, others by fibrous union, and in one case the fragments of the ilium, though united on the internal surface by bony callus one centimetre thick and four wide, showed not the slightest trace of any effort at repair in the exterior. In another case the fractured head of the femur, instead of uniting with its shaft, had consolidated with the ilium in an acetabulum so eroded that the femoral head could be seen from the pelvis. Moreover, the head of the femur and the floor of the acetabulum projected as a bulging tumor into the pelvic cavity.

It is of not a little interest to observe that the very first hint of the spinal origin of these joint diseases was given by the late Prof. J. K. Mitchell, of this city, in the *American Journal of the Medical Sciences* so long ago as 1831 and 1833, and that his son, Dr. S. Weir Mitchell, in the same Journal, in 1873 and 1875, has made some of the late and, we regret to add, rare American additions to our stock of knowledge in reference to such articular and osseous lesions. To Charcot, however, more perhaps than to any other one author, do we owe our knowledge of the subject. He has insisted, as opposed to Volkmann and others, that the lesions are not traumatic but spinal in their origin and trophic in their character, and, again, that the joint disorders are totally distinct from those of ordinary dry arthritis.

Certainly specimens and cases, such as these and others which he has described in his *Leçons*, seem to prove both of his points to be well taken. The period at which the troubles occur, long before the incoördination of the later disease; the absence of prodromata; the malignancy of the disease, as evidenced by the rapid and complete erosion and even disappearance of the whole upper end of so large and stout a bone as the femur, with other almost as striking characteristics, are *primâ facie* evidence of the correctness of his view. Moreover, the peculiar articular lesions following injuries to the peripheral nerves, as well as of the cord, first pointed out by Weir Mitchell and his colleagues during the late civil war, and now well recognized as clinical facts, are very strong evidences in favor of the neurotic origin of such osseous and articular lesions, even though of so extraordinary a character.

THE TREATMENT OF TYPHOID FEVER.

In a recent discussion before the *Académie de Médecine*, Dr. Dujardin-Beaumetz passed in review some of the methods now most employed in the treatment of typhoid. These methods may be referred to two categories: the antipyretic; the antiseptic. The antipyretic consists chiefly in cold baths and massive doses of quinine. The bath treatment is not without danger in the way of causing congestion of the lungs, and the use of quinine in the large doses now employed would produce toxic effects if it were absorbed, but the greater part of it may be recovered from the stools. Salicylic acid causes stomach trouble: and if well borne does not modify in any way the severity of the disease, or lessen its duration. Carbolic acid is a dangerous medicine, which may induce collapse or set up pulmonary congestion. In the estimate made of any plan of treatment, the type of the epidemic must be taken into account.

Rejecting thus in turn the various novelties of treatment, Dr. Dujardin-Beaumetz maintains the superiority of that which he styles "the classical." It consists in the occasional administration of purgatives, a proper alimentation, careful attention to the hygiene of the patient, and the use of means to combat unfavorable symptoms as they arise. In other words, except the use of purgatives, his method is that entitled "expectant" in this country.

STRAW IN THE STREET CARS.

Notwithstanding the comparatively recent introduction of street passenger cars, there remain certain usages connected with their service which are relics of the barbarous past, and which are totally void of excuse. Notable among these barbarisms is the condition in which our horse-cars are kept during the winter months.

While cars transported by steam are models of comfort, and even luxury, the comfort and health of those multitudes who are compelled to use the street-cars of our large cities are treated with absolute contempt. Nay, there would seem to be a reckless disregard of the comfort and health of those who patronize these vehicles.

Let any one fresh from reading a description of Koch's investigations on the "bacillus tuberculo-

sis," enter a street car on a wet, muddy, winter afternoon. Let him glance at the damp, soggy, straw or hay which covers the floor, and notice the frequent expectoration in the material thus carefully provided for the cultivation of germs, and we defy him to avoid the ardent hope that Koch is in error, and his bacillus imaginary. No wonder that so many prefer to take their chances of pneumonia and pickpockets upon the rear platform.

Should the day be cold, and the door and windows be carefully closed in consequence, the street-car traveller may reflect upon the scars adorning his neighbor's face, and amuse himself by estimating how many as yet undetached variolous crusts still adhere to his person, or he may pursue his reflections so far as to speculate how many may become detached and find a resting-place in the luxurious hay carpeting at his feet.

We need not follow the investigator into his speculations concerning the whole list of contagious diseases. Of one thing we may rest assured, that he will arrive at the conclusion that the ingenuity of man has not devised any one thing better fitted to both concentrate and disseminate morbific poisons than the average horse-car in winter. Such a state of things is a disgrace to our civilization, and results from an utter absence of progressive spirit on the part of the managers of these corporations. It comes from simply allowing things to remain as they were in the beginning. In this case there is every reason why they should not so continue, and there is no excuse for street cars not being both properly warmed and ventilated, since numerous efficient devices to this end are in the market.

The enormous power wielded by street railroads makes it difficult to deal with the matter by municipal legislation. Nevertheless, the evil is a great one, and is worthy of most careful consideration by all who are interested in the health of the public.

THE QUALIFICATIONS OF A HEALTH OFFICER.

THE rapid advance in sanitary knowledge, and, as a consequence, the more exacting demand for a careful and wise administration of sanitary law, requires a rigid scrutiny into the qualifications of all executive officers of health. So varied and responsible are the duties entrusted to the health officer of a large town or city that, without special knowledge and training, and good administrative ability, the holder of the position cannot successfully discharge the obligations of the trust. Recognizing the soundness and wisdom of this principle, the local government of England has long since required that all health officers shall be medical men, who, by education and training, are especially fitted for the work of investigating the causes and prevention of diseases, the management of epidemics, supervision of sanitary inspections, and the intelligent administration of the laws of health.

It happens too often in this country that the position of health officer is one of political reward, without consideration of personal and professional qualification. The result is an inefficient, haphazard, and automatic execution of the laws, and a failure to judiciously and efficiently carry out the duties of the office, through ignorance of the fundamental principles of public and private hygiene.

A health officer should be an experienced sanitarian, and a physician of thorough education. He should be capable of advising the sanitary authorities in all matters affecting the health of the people, and he should be competent to intelligently inquire into the causes, origin, and distribution of diseases, to ascertain to what extent they are capable of removal or mitigation, and to make use of all the means at his disposal for the preservation of the public health. He should give his entire services to the position; he should receive a liberal compensation, and should have the assurance of continuance in office so long as the duties of it were judiciously and efficiently discharged. The present uncertain tenure of office is a bar to an eligible appointment, as none but a professional office-seeker is willing to throw aside the advantages of a permanent avocation for an office of uncertain tenure.

The recent selection of a health officer for Philadelphia ignores the fact which we have endeavored to set forth that special knowledge and training are preëminently the qualifications required for such an important office.

LEITER, the well-known instrument maker of Vienna, has introduced an apparatus for the local application of heat or cold. It consists of a flexible metal tube, which may be made to adapt itself to any surface. Thus, if it is desired to apply a given temperature to the abdomen, the tube is coiled on itself until it has the proper size, and moulded to fit the surface. The entrance tube is connected with a vessel containing water at the desired temperature, and the exit tube empties into any suitable receptacle. The principle is by no means new, but the adaptation of flexible metallic tubes which can be moulded to any unequal surface, is the point of novelty. At Billroth's clinic these tubes have been employed by Dr. Mikulicz in joint inflammations, in phlegmon, in traumatic delirium, in erysipelas, in rapidly growing sarcomata, and in neuralgia. Sometimes heat, sometimes cold, is found to be more effective. They are applied with equal facility, of course. The ordinary rule for their application is equally operative in the use of these tubes—the sensations of the patient being the true guide to the degree of heat or cold respectively.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, January 18, 1883.

THE VICE-PRESIDENT, ROBERT F. WEIR, M.D., IN THE CHAIR.

THE SECRETARY read a letter from Dr. Charles Mill, in which he presented an elaborate engraving of John Hunter to the Academy. Enclosed was a printed slip, taken from *Harper's Magazine*, descriptive of the engraving. The engraving was the work of Mr. William Shaw, a celebrated engraver of the last century.

DR. ADAMS said that the original portrait, from which this engraving was made, was in St. George's Hospital. He moved that the thanks of the Academy be extended to the donor for his generous gift.

The first paper of the evening was by Dr. PAUL F. MUNDÉ, and was entitled,

SECONDARY PUERPERAL HEMORRHAGE.

While the occurrence of more or less alarming uterine hemorrhage immediately after or during the first twelve hours following delivery is by no means uncommon, and has been thoroughly discussed in all the text-books and in the current medical press, the subject of metrorrhagia at a later period of the puerperal state, so-called "secondary hemorrhage," has received comparatively little attention.

The author reported the case of a woman twenty-five years of age, whom he had seen in consultation in her fourth labor, which was very tedious, and after it had lasted for twenty-one hours, the forceps were applied, but slipped. After a short time delivery was effected by perforating the cranium and applying the cephalotribe. The cause of the difficult labor was hydrocephalus. On the sixteenth day she was taken with profuse hemorrhage, which soon threatened her life, but from which, by appropriate treatment, she ultimately recovered.

The subject of secondary hemorrhage occurring at a late date was then considered, and the paper concluded with the following brief rules for the management of the third stage of labor, and the early puerperal state:

1. Always keep the supporting and compressing hand on the fundus uteri from the moment the head appears at the vulva until the placenta is expelled.

2. Do not hasten the expulsion of the placenta too much, but by steady, gentle friction of the fundus endeavor to obtain its total spontaneous detachment, the occurrence of which can easily be detected by the uniform firm outline of the contracted uterus on palpation.

3. Always watch the uterus with the hand, using gentle friction for at least an hour, at intervals, before leaving the patient.

4. Always give ergot (one drachm or more of the fl. extr.) by the mouth, immediately after the birth of the child. If chloroform has been given for an operation, or if the labor has been unusually tedious, give the ergot hypodermically, injecting a syringeful of the fl. extract to the depth of one inch, near the umbilicus. It is always advisable to have the syringe filled with ergot, and to see that it is in good working order, before the conclusion of the labor.

5. Always have ice on hand; and if the uterus shows a reluctance to remain contracted, rub the fundus gently with a piece of ice, or insert a cone-shaped piece into the cavity. (As a rule, the injection of *hot* water, while a powerful styptic, is less agreeable to the patient at this time, and will scarcely be employed unless actual hemorrhage occurs.)

6. Always make sure by palpation and compression that the uterus contains no coagula, and if such still form at once express them.

7. Aid in securing permanent contraction of the uterus by an early application of the child to the breasts.

8. If the labor has been tedious or instrumental, or the uterus contracts badly, or the patient is not to nurse the child, or is constitutionally feeble, it is wise to guard against sub-involution and a long continuance of the bloody lochia, by giving the patient a pill containing one or two grains of Squibb's aqueous extr. of ergot, two grains of quinine, and one-third of a grain of extract of nux vomica, three times a day, for ten days or two weeks, or longer, beginning on the day after delivery. If the stomach is irritable, this combination may be given in rectal suppositories, the quantity of ergot being doubled.

9. Before leaving the patient, an equably tight binder should be applied, and if there be tendency to hemorrhage, a pad should be placed under the binder over the fundus, to secure its steady compression.

10. Examine the cervix and vagina with the finger immediately after delivery, and if there be a laceration of either, be prepared to check possible future oozing by mild astringent injections, or, if need be, applications through the speculum. (Immediate suture, as recommended by some, appears to be rarely feasible.)

11. Do not allow a lying-in woman to make rapid motions in bed, strain, sit up suddenly or very long, or to leave her bed before the tenth day.

12. Keep watch of the bladder, particularly during the first twenty-four hours, and assure yourself by palpation and percussion that it is empty and is not interfering with uterine contraction.

13. Instruct the nurse not to insert the nozzle of the syringe too far, or to use too much force in giving the customary cleansing injections, for fear that the cervix may be bruised.

DR. POLK thought that the causes of secondary uterine hemorrhage were not dissimilar to those of hemorrhage occurring elsewhere. Hence, it has been his rule, when he had found slight hemorrhage, to be on his guard against those conditions which were generally supposed to predispose to hemorrhage. If uterine contraction takes place in the first instance and coagula are formed and are permanent, there will be no hemorrhage; but if, in consequence of disease, lymph is not exuded, and the vessels do not contract properly, and the proper organization of the tissue does not take place, the clot is absorbed and the mouths of the vessels remain open. Now, the conditions which will interfere with the proper closure of the vessels are very numerous. Among these should be mentioned, first, those included under the term of pueperal fever. These prevented the contraction of the uterus, and at the end of four or five days we would find the fundus of the uterus in the neighborhood of the umbilicus. The other conditions are mainly constitutional, and may be summed up under the head of any of the cachectic states, such as malarial, or those conditions due to the poisonous effects of minerals, such as lead or mercury, or any substances that might interfere with the plasticity of the blood. He believed there was a large number of conditions, any one of which might give rise to hemorrhage, provided we have a certain amount of interference with the organ itself, such as washing it out, premature intercourse, retention of urine, etc. He was sure that he had seen a good deal of prostration in consequence of the prolonged use of cold in this condition, and also that he had never seen any ill effects from the use of hot water, which should be as warm as the hand could readily bear.

DR. PARTRIDGE agreed with Dr. Polk as to the causes of secondary hemorrhage, and if he were asked to point out a woman who would be likely to suffer from secondary hemorrhage, he would select one with flabby muscles, irregular cardiac action, and such symptoms as were attributable to defects in the circulatory system; also, those suffering from derangement of the sympathetic system. He once had an alarming case of secondary hemorrhage occurring on the ninth day after labor. When he reached the patient, she presented symptoms of extreme loss of blood, her face was pallid and she was in a state of syncope. The uterus and vagina were filled with clots, and the bed-clothes were saturated with blood. Upon examination, it was found that there was an annular slough of the vaginal end of the cervix, from which a profuse hemorrhage had occurred. In this case there was an early rupture of the membranes, owing to the frequent pains and great pressure of the head. In studying this subject, he had found that in cases where there was resistance to the downward coming of the head, there was more tendency to uterine hemorrhage.

With reference to treatment, he thought there was very little more to be said; when such a condition of the general system as he had pointed out could be recognized, he thought it was of importance to watch the patient with exceeding care. In regard to local treatment, if the hemorrhage depended upon laceration, he would say use iodine applied to the bleeding surface with cotton. Septic absorption was not common before the tenth day, but it sometimes occurred earlier. In most cases of laceration the separation of the slough occurred on the seventh day, but in those cases where the laceration was of very considerable extent, the separation of the slough did not take place so soon. In such cases, the use of the tampon was particularly to be avoided. He could not use the tampon unless other methods had proved useless. He concurred in the opinion as to the non-desirability of sewing up the cervix at such time.

DR. HANKS remembered a patient coming under his observation who suffered from excessive uterine hemorrhage occurring fourteen days after confinement. In this case, the cause of the hemorrhage was undoubtedly due to malarial poisoning. Though the patient was thoroughly exsanguinated, yet after washing out the cavity of the uterus with warm carbolized water, she finally rallied. He had had another case undoubtedly due to malarial poisoning, which came on nine days after confinement. In this instance the hemorrhage was controlled by intra-uterine injections of hot water. He did not usually make use of the tampon, and would not recommend it on account of the difficulty of applying it under such circumstances. He thought that the application of iodine could generally be relied upon to arrest the hemorrhage. He begged to differ from the author in the use of ergot in all cases after labor. He did not think this practice was necessary. What was necessary, however, was to watch the patient carefully, and if there were any signs of danger, then to use ergot.

DR. MUNDÉ preferred the introduction of a conical piece of ice into the cavity of the uterus to the injection of hot water, as he thought it would be as efficacious as the latter, and more agreeable to the patient. The subject of chronic lochial discharge, or, as it has been termed, *hemorrhagica lochialis*, he thought was of sufficient importance to demand separate consideration. These cases of profuse lochial discharge might continue for months. They were due to want of uterine contraction, and to the formation of healthy mucous membrane. As to the use of the tampon, he would not recommend its introduction into the vagina after the delivery of a full-grown child. In the use of ergot he saw no evil effects beyond the slight nausea, and he thought it was a safe practice to use it in all cases. He would, however, consider its use hypodermically as unnecessary, except where it was especially called for to arrest hemorrhage.

The next paper was by DR. EDWARD B. BRONSON, and was entitled

ECZEMA, ITS PATHOLOGY AND PRINCIPLES OF TREATMENT.

The author referred to the importance that is generally attached to the changes that take place in the vascular layer of the skin, in eczema. The part played by the epidermis in this disease was commonly regarded as secondary and subordinate. He maintained that the epidermic lesions were rather of a primary and initiative character, and considered the epidermis to be the focal point of the eczematous process. The researches of Velpeau and others had shown that the cells of the rete Malpighii took an independent part in the disease that was analogous to that of the endogenous formations that characterize inflammation of other non-vascular structures, such as cartilage tissue, the cornea or the epithelium of the epiploa. The formative changes that took place in these structures when inflamed, originated in the normal, endogenous cells of the part and not in cells that had wandered from the bloodvessels. But though the pathological process was initiated in the cells of these structures, the adjacent vascular tissue soon sympathized. The papillary vessels responded to an irritation in the epidermis, as did the subconjunctival vessels in irritation of the cornea.

Next the qualifications of the epidermis for initiating an irritative process in the skin were considered, and in this connection, reference was made to recent researches concerning the cutaneous nerves—more especially the nerves of the epidermis. Of these researches, the most important were those of Pfitzner and Unna. These investigators had shown that each prickle cell in the rete mucosum was provided with two nervous filaments which penetrated the cell wall and terminated within the cell by bulbous extremities. It was urged that this extraordinary nervous supply to the epidermis could not but have an important bearing upon the pathology of eczema.

The most constant and essential factors in eczema were sensory disturbance and trophic change in the epidermis. The trophic changes that took place in the derma were regarded as secondary and contingent. Impairment of the integrity of the epidermis was the necessary condition of every form and phase of eczema. It, more than any other feature of the disease, distinguished it from the erythematous diseases. The desquamation that occasionally occurred in the latter was the result simply of nutritive impairment due to vascular disturbance beneath, but in no wise corresponds to the degenerative lesions of the epidermis in eczema. It was probable that this trophic change of the epidermis in eczema was under the influence of the epidermic nerves.

Furthermore, it was claimed that the sensory disturbance so characteristic of the disease, viz., the itching, was owing to disorder of these nerves. Evidence was adduced to show that the diseases of the skin which are attended with pruritus always implicate, in a marked degree, the mucous layer. In urticaria, the lichens, prurigo, scabies, and vesicular diseases in which the vesicle was deep seated, sensory disorder was an important feature, and in all of them the mucous layer was markedly involved.

No great importance was attached to the different lesions of the nerves that have been described as associated with eczema. They simply served to show the intimate relation of the disease to the nervous

system. The initial motive of the morbid process—exciting cause—might be developed from various sources: direct external irritation of the epidermis, reflex irritations, central nervous derangement, or diseases of the nerves, either in their continuity or at their periphery.

Eczema, then, was a disease the main factors of which were a cutaneous inflammation of a catarrhal character, seated primarily in the mucous layer of the epidermis, involving the derma incidentally to a greater or less extent, and accompanied with marked disorder of the tactile sense.

Ordinarily there is but little tendency to spontaneous recovery.

The obvious therapeutic indications are, first, to allay irritation, and second to assist repair.

The first requires the elimination, as far as possible, of all sources of irritation, whether extraneous or inherent, together with the protection of the damaged epidermis. The second indicates the use of such stimulants as will combat the tendency to chronicity. Measures of rest and measures of stimulation constitute the whole treatment of eczema. Two methods are possible—mediate and immediate—the first by internal, the second by external medication. The accessibility of the suffering tissue in eczema would naturally suggest the method of direct application, which was first considered.

The agents used in the local treatment of eczema are either mechanical, chemical, or dynamic in their action. Mechanical agents are chiefly valuable for protection, answering the same purpose as the simple dressing in the treatment of a wound. They include various inert powders, lotions, simple ointments, and emollient applications generally. The indications for the different varieties of this class are not precisely identical. As a rule the highest grade of inflammation, as in the acute erythematous form, is best treated by wet applications. These abstract local heat by evaporation, and prevent local desiccation of the superficial epidermis—a harsh, dry condition that tends to increase the irritability of the subjacent nerves. The lotion may either hold in suspension powdery substances that collect upon the epidermis and supply a soothing envelope, or it may contain chemical materials that exert a slight modifying influence, such as mild astringents or alkalies. Lotions, however, if employed, should be used continuously. Alternate wetting and drying of the inflamed skin increases the irritation. A small quantity of glycerine generally improves the wash. Undiluted glycerine is an irritant. Emulsions, also, are well suited to this stage of the disease. When the inflammation is less intense (acute papular eczema), the insoluble powders are the best application. Between lycopodium, starch powder, talc, calamine, oxide of zinc, bismuth, and the like, there is little to choose, if only the applications be copious and frequent. The effect is increased by first smearing the skin lightly with cold cream, glycerine and water, or some soothing emulsion, thereby affording a surface to which the powder will better adhere. A little later comes the period for the use of ointments. The skin has become rougher and harsher, the cuticle brittle and ragged, the surface covered with scales, crusts, and abrasions. Vesicles appear here and there, or, more commonly, minute punctate excoriations. From this time forth the cure is usually hastened by the continuous protection of an appropriate ointment, until the epidermis is sufficiently regenerated to perform its protective functions unaided. Such an ointment should be absolutely non-irritating, smooth, homogeneous, and free from rancidity. It should not be so greasy as to be easily displaced; it should not soften the cuticle so much as to render it more vulnerable; but should be of a proper consistency to afford a perfect shelter to the exposed and irritable structures, and at the same time prevent undue desiccation. It is difficult to find any application that better meets all these requirements than our common zinc ointments. Rarely is any other preferable. Under its protection and control, stimulation may be produced by certain measures, intermittently, or, if desired, more constantly, by modifying the ointment by the addition of various medicaments.

But eczema has certain phases to which ointments are not suited. As already indicated, they should not be begun at a very acute stage of the disease. Furthermore, where the surface is eroded and exudes a copious and ichorous discharge, the effect of an ointment is generally unfavorable. An astringent wash or, better, an absorbent powder is preferable. Gypsum, if free from gritty particles, added in the proportion of one to four or one to eight, increases the absorbent power of the powder.

A class of agents, the action of which is far more complex and obscure, is the group that acts as modifiers of vital action. By far the most important of these are the alkalies. Their value in almost every stage of the disease has long been established. In fact, inflammations of cutaneous and mucous surfaces, almost without exception, are beneficially affected by their use. Their sedative influence is an important element in their action. No more certain anti-pruritic exists, and no remedy affords greater relief for the heat and burning of an inflamed skin than external alkaline applications. The virtues of the alkaline bath are rather under than over-estimated. Although medicinal agents are probably unable to penetrate the intact cuticle, yet when applied over an extensive surface they gain sufficient access to produce decided effects. Employed over a small surface the alkaline effect is very marked when the corneous layer is abraded and the nervous structure of the epidermis exposed. Dilute alkaline washes answer well for the acute stage of eczema. Later, when pathological products, difficult to dislodge, accumulate on the surface, alkaline soaps are preferable. In old chronic cases with decided thickening and thick laminæ of adherent scales, the stronger potash soaps are indicated, as the "Schmierseife" of the Germans, or, better, the "Sapo Olivæ Præparatus" first brought into notice by Dr. G. H. Fox. When the scales and crusts are thinner, the milder soda soaps should be used, preferably those made with glycerine and a small proportion of alkali. Lang's, Rieger's, or Pears' soaps are the best.

In squamous eczema, the "soap treatment," which we owe to Hebra, if thorough, has no equal, and the relief is almost immediate. The frictions themselves would cause useless irritation did they not remove the source of greater disturbance. In squamous eczema there are almost always vesicles deep down in the rete, imprisoned by desiccated epidermis or dried secretion above. The epidermic nerves are intensely irritable. The soap clears away the irritating pathological products, evacuates ichorous fluid formed in the vesicles, and brings the liberated alkali into direct contact with the diseased tissues, thereby modifying the pathological processes, and exerting a direct sedative influence upon the adjacent nerves. Moreover, the stimulating effect doubtless promotes absorption and assists reparative effort. Seldom is any stronger alkali than that contained in soap required. For simple caustic effect, agents that act more superficially are preferable, as carbolic acid or nitrate of silver. The latter, or its solution, is generally most useful in circumscribed forms of moist eczema, in which there is a pyogenic condition. Hot water is of value to allay the pruritus of eczema. It accomplishes this by first substituting the sense of smarting for the itching, and

later by its direct sedative action. The hot water should not be stopped too soon, if the full benefit of its use would be derived. Violent scratching temporarily relieves the itching, the "paræsthesia" of pain prevailing over and excluding the paræsthesia of pruritus. Carbolic acid is a very useful remedy in eczema; when strong, it annihilates vital action; moderately concentrated (from ¼ to ⅛), it allays local excitement and produces sedation; dilute, it acts similarly to the tarry remedies. Irritable fissures are benefited by strong applications. Moderately strong solutions have decided anti-pruritic virtues. They are especially adapted to cases in which the area involved is small and the itching intense, as in eczema of the anus. Dilute solutions are useful in those cases benefited by tar and its congeners. Tar in cutaneous affections probably acts as do terebinthinate and balsamic substances in diseases of the mucous membrane. They are generally most useful after the acute stage has passed, when the nerves have lost some of their preternatural irritability, and the condition is one of impaired energy, of relaxation, and of congestion, more or less passive in character. They improve vascular tension, and check excessive secretion. They should be employed at a comparatively later period in eczema than the corresponding remedies in inflammation of the mucous membrane; perhaps because in the latter case, when the drug reaches the seat of trouble, it has become less irritating by dilution or modification of its ingredients. It is a good rule in eczema, that during the stage of active exudation in the mucous layer, tar is contra-indicated.

Little need be said of narcotics. Certain of them, however (notably camphor), because of their volatility are useful adjuvants in case there be pruritus.

Mercurials, though sometimes beneficial early, are chiefly of value in the latest stage, when acute inflammation has subsided, but when nutrition is interfered with by the products of inflammation accumulated mostly in the cutis and subcutaneous tissues. Mercury is especially useful in removing such products, fibrous or cellular, because of its hostility to living organisms. It attacks first recently formed and imperfectly formed tissues, impairing their vitality and predisposing them to rapid subinvolution and resorption. Besides this—its peculiar, its pathognomonic action—it has also a stimulant and substitutive effect.

The "impermeable dressings," more especially the rubber applications, are decidedly advantageous in advanced eczema with marked thickening. They macerate desiccated and thickened cuticle, the removal of which enables the deep vesicles to discharge. They also cause a substitutive inflammation, which, by countervailing the chronic eczematous process, assists repair. When the artificial inflammation becomes severe the dressing must be removed.

Though the agents enumerated embrace a wide range in therapeutics—emollients, sedatives, astringents, irritants, excitants, and alteratives—they are divisible into two classes corresponding to the two main indications for the treatment of the disease. To one class belongs the function of protection: to the other that of aiding and directing reparative effort. Early, before the morbid habit is confirmed and the natural reparative power seriously impaired, protective measures alone may suffice. Furthermore, they are indicated during the later stages, to prepare the way for stimulant or modifying agents, and to control their action. It is upon the proper apportionment of these two opposed, but virtually coöperating, therapeutic measures that success in the treatment of eczema will mainly depend.

The indications supposed to call for internal medication may be divided into four sets: (1) For the relief of internal disorders that affect the skin by reflex irritation. (2) To remedy general debility or special systemic diseases that are accompanied by defective innervation or innutrition of the skin. (3) To reinforce the local resources of repair by the administration of drugs that either act directly on the skin by selective affinity; or, else (4), To set up internally a transpositive irritation to divert a share of the cutaneous excitement to other organs.

Sometimes eczema appears to be due to internal causes, because of the absence of any unusual source of external irritation. Oftener it results from the combined effect of an irritation acting from within, and another acting from without. Reflex irritation, such as disturbance of the digestive or generative functions, rarely suffices alone to cause the disease; but when it is prolonged, the cutaneous nerves become so irritable and debilitated that they can no longer tolerate such external influences as, under ordinary circumstances, would be insignificant. Moreover, in systemic diseases attended with a general debility, gout, rheumatism, lithæmia, uræmia, diabetes, and the like—the nutrition of the skin suffers in common with that of other tissues, and these develop a predisposition to disease. Still further, back of the predisposition arising from conditions that affect the general health, it is necessary to infer the existence of a special cause that determines the cutaneous outbreak in that limited class of individuals known as the eczematous. The French school of dermatologists attribute this special cutaneous susceptibility to a special dyscrasia. Eczema is the expression of a systemic malady which at certain periods and under various influences becomes intensified, betraying itself by the appearance of the characteristic lesions of the skin. Of this peculiar diathesis, "*les dartres*" constitute the sole manifestation and evidence.

But is this the only possible explanation? Is no consideration due the inherent nature of the skin affected, its peculiarities of organization, the measure of its tolerance of irritating influences? Why should not the skin in different individuals differ as widely in its constitution and morbid tendency as do their other organs, their nervous, digestive, pulmonary or muscular systems? Some weaknesses arise from defects of anatomical structure; in others, defect of organization is less patent, but is betrayed by frequent derangement of function and proneness to disease. Thus in the eczematous subject, though his general health is not necessarily impaired, at every departure from health the skin is quick to take offence. Whatever may have been the original internal or external exciting cause the cutaneous effect is often a wholly disproportionate one, one that could only be produced upon an organ capable of but feeble resistance. The eczematous usually, but not always, have dry, harsh, irritable, itching skins; moreover they differ in degree of vulnerability and in disposition to recover from the outbreaks.

The external manifestations are constant because eczema is the natural expression of a simple inflammatory action of the mucous layer of the epidermis. When an irritation can no longer be tolerated by this tissue, its vitality succumbs, and the legitimate outcome is eczema. Its physiognomy is not always the same, and it is possible that there may be allotropic forms depending on individual peculiarities. These may so differ from the simple type as to present the features of a different disease.

Therefore, whatever causes in the economy at large may predispose to eczema, the most essential predisposition is in the skin itself. Eczema, then, is essentially a local disease, and the most rational treatment is that which addresses itself most directly to the offending part. Oblique methods, however, are of value, and should not be ignored. At the outset, and

in obstinate cases generally, powerful internal diversion will often so allay the cutaneous excitement as to determine the success of the local treatment. Tonics, regimen, diuretics, purgatives, alkalies, in discreet hands are invaluable adjuvants. Internal medication must always be subordinate. There is no "specific" for eczema. It will not do to depend on the "selective affinity" of internal agents for the tissues affected in the disease. Narcotics should be mentioned, but to be condemned. Manifest derangements of special organs or of the general system should be appropriately treated. In chronic eczema the original cause has usually long ceased to be operative. In the majority of cases local treatment is well able to cope with the disease single-handed.

DR. TAYLOR remarked that we have cases where the whole skin is involved, and in some cases the subcutaneous tissue beneath it, so that if the author would include this in his description of the pathology, he thought it would make his paper more complete, though he conceded its excellence in its present form. The principles of treatment, Dr. Taylor believed, could be formulated somewhat as follows: In the first or erythematous stages of the disease, soothing applications in the form of powders, starch, oxide of zinc, arsenic, calomel, with the addition of camphor as a slight stimulant, or a lotion, as lead and opium wash; later in the disease stimulants should be resorted to. He thought that the proper use of stimulation was one of the cardinal points in the treatment of this affection. Protective agents should first be used, and then stimulants. He agreed with all the author had said with regard to the use of soaps. In many cases he thought that we could go a step further, and even make use of strong solutions of potash. Soaps would sometimes fail where potash in strong solutions (say a drachm of caustic potash to an ounce of water) would succeed. The production of additional inflammation should be avoided. He was glad to hear the author take the ground that he did in regard to the nature of eczema. He believed that, whatever the general condition of the patient was, the disease itself was a local trouble. There was one point which he thought was not well brought out, and that was that patients not infrequently apply for treatment with eczema who have had it for a long time. In these cases, if we go back into their history, we find that in early life the patient had suffered from repeated attacks of local eczema. In this way the tissues had been rendered more vulnerable all through life than they otherwise would have been. He thought it could be stated that, as a rule, the more frequent the attacks in early life, the more liable the patient was to late attacks. In regard to the use of internal remedies, he agreed with the author as to the desirability of administering alkalies. He thought that one remedy had been neglected by the author of the paper, and that was arsenic. Arsenic would assist the internal treatment very much. The golden rule in handling cases of eczema was to look after the local treatment. Arsenic had a good effect upon the skin. If he were to indulge in a theory as to its action, he would say that it stimulates the capillaries, giving them tonicity, thus enabling them to hold their own.

DR. BULKLEY thought that the subject of alterations in the cellular layer of the skin was an exceedingly important one, and of late years had received insufficient attention He had been much interested in noting the effects of tobacco in this disease. His attention had been called to a case of eczema of the anus by Dr. Frank H. Hamilton, in which the patient had a recurrence of the disease each time he used tobacco. He had watched the influence of this practice upon this class of cases in a number of instances. One case had come under his notice where an attack was brought on by smoking a single cigar. These facts, he thought, had a bearing in the direction of the nervous origin of eczema. Dr. Bulkley thought that in the majority of instances it would be found that patients suffering with eczema were not otherwise perfectly healthy. He had great confidence in the use of the tonic treatment combined with alkalies. It has been said that there is no specific for eczema, and he himself had made such a statement. He had, however, reported several cases of the disease recurring in children where the use of arsenic internally, without any local treatment whatever, had resulted in a rapid cure.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, December 28, 1882.

THE PRESIDENT, JAMES TYSON, M.D., IN THE CHAIR.

TUBERCULOSIS OF SPLEEN, LIVER, AND KIDNEYS.

DR. SHAKESPEARE exhibited these specimens without a history of the case. They showed exuberant vegetations in pericarditis, abundant miliary tubercles of the pleura, of the liver, of the spleen, of the kidneys, and of the lymph glands in the region of the head of the pancreas. They were brought to the notice of the Society mainly because the members had not had many opportunities of examining such perfect examples of extensive and diffuse tuberculous infiltration without more serious involvement of the parenchyma of the lungs.

Autopsy (six hours after death).—C. J., colored, æt. 60. Diagnosis: Pericarditis and pleuritic effusion, with strong bands of adhesions between parietal and visceral pleura. Thorax: left pleural cavity completely obliterated by adhesions; right pleural cavity contained a large amount of straw-colored serum. The lobes of this lung were compressed against the spinal column, and were stalactitic. The lower lobe was firmly adherent to the diaphragm, and the three lobes were strongly united by adhesions. The parietal pleura was thickened and everywhere studded with minute, gray, semi-opaque miliary tubercles; the visceral pleura was in a similar condition, except that the tubercles were less numerous. The cut surface of the right lung presented nothing abnormal, save absence of air, but the sense of touch showed beneath and near the pleura a few scattered minute points, much smaller than millet seeds. The pleura of the left lung was also studded with numerous miliary tubercles, and the tissue of this lung was similar to that of the right; it was, however, crepitant. The pericardial sac contained 2½ ounces of straw-colored serum. The whole heart was covered with an exuberant crop of vegetations. The cardiac walls were perhaps slightly softer than usual, otherwise normal. Abdomen, peritoneum, normal; no effusion; liver slightly enlarged, with surface here and there raised by flat elevations ranging in size from a hempseed to that of a hazelnut; capsule normal. The nodules were firm and of a yellowish tint; the intervening tissue was of a dark red. Deep section of the organ revealed similar nodules diffused through its substance, which seemed otherwise firm and normal. The spleen was slightly enlarged, firm, and extensively infiltrated with tubercles. The pancreas was normal, but the lymph glands near it were much enlarged, but neither softened nor caseous; no caseous focus was anywhere detected. The kidneys appeared normal, except for one or two more or less pyramidal yellow points. The case presents several points of interest: 1. Former history unknown. 2. Several aspirations, removing considerable pleuritic fluid. 3. What was the origin of the numerous tubercular irruptions, and if there was

auto-infection, what was its probable source? Dr. Tyson then gave a *résumé* of the ante-mortem history.

DR. TYSON said he regretted having to admit that he was less familiar with the history of the case than he should have been, since the patient was in his own wards in the Philadelphia Hospital. Thoracentesis had been performed more than once. The patient was a colored sailor, aged 60 years. When Dr. Tyson took charge of the ward in September, the man presented the physical signs of double pleuritic effusion, orthopnœa, and feebly transmitted heart sounds, but no cardiac murmur. There was œdema of the legs. He was tapped with great benefit, and under a restorative treatment he rapidly improved, so that he soon became one of the walking cases in the ward, attracting little attention. About December 1, he became very much worse. The orthopnœa and other signs of accumulating fluid returned, and so did the œdema of the legs. His urine was repeatedly examined for albumen, with negative results. He was tapped upon the right side and three pints of fluid removed, with but partial relief. The other side was also aspirated without success. A cardiac friction sound was noted, which seemed to be pleuro-pericardial, but in the light of the autopsy it was probably pericardial. He died on the 13th of December. He was unacquainted with the temperature record.

DR. MUSSER said that a relationship between pleurisy and pulmonary tuberculosis could not be denied, but whether the pleurisy or the tuberculosis be antecedent, was difficult of solution. That the former is primary may be inferred from the fact that persons are considered as threatened with phthisis who have subclavian arterial murmurs, due to the pressure or pulling on the artery of organized lymph. Likewise are the various friction sounds and exocardial murmurs noted to precede tuberculosis, and especially to occur in those tuberculously predisposed. Examples of both cases have come under his observation. It seemed to him that a primary acute pleurisy is a rarity, occurring in a non-tubercular subject. The last series of cases of what would be called primary pleurisy he had seen were in persons predisposed to tubercle, and in some of the cases tubercle subsequently developed. In short, so called primary plastic pleurisy occurs only in tuberculously disposed individuals; other forms are secondary to some other process, as Bright's disease, septicæmia, etc. Trousseau calls attention to latent pleurisies with effusion, as being often an expression of a tuberculous diathesis, while also a latent pleurisy may occasion development of that diathesis. Two cases illustrating these views have lately come under his notice.

DR O'HARA said that although he had not had much experience with latent pleurisy, he recalled a case of a young man seen five years ago, where extensive effusion into one side of the chest had unexpectedly occurred, and when detected had been removed by tapping. Apparent recovery then ensued, to be followed in a few weeks by copious effusion into the other pleural cavity. Tapping was again resorted to, the effusion never recurred, and the patient remains healthy and free from tubercle at the present time. He would like to ask if when the term "all the serous membranes were affected" was used, those of the brain were included.

DR. TYSON replied that there had been no head symptoms in the sailor's case.

DR. SHAKESPEARE closed the debate by referring to the causes of tuberculosis in general and its mode of diffusion through the organism. He called attention to the failure in discovering any caseous focus, while admitting the possibility of such, if minute, escaping the most painstaking search. In this and similar cases all that could be safely said was that *the caseous point was not found*. Assuming, for illustration, that the point in the kidney might have been the origin of the auto-infection in this case, he referred to the communication between the left renal vein and the inferior mesenteric vein, and the direct communication with the portal system thus effected. As to the point raised by Dr. Musser, he believed in plastic pleurisies distinct from tuberculosis. He had examined very many microscopic sections of pleuritic adhesions, and very many had proved to be free from tubercle. Authors who have made original investigations on man and the lower animals, have also as distinctly recognized a plastic pleurisy without tubercle, as they have one associated with this formation. He thought tapping in a person not predisposed to tubercle was no more likely to produce this disease than tapping an anasarcous limb. He was well aware of the facts dwelt upon by Drs. Musser and Formad, viz., the association of tapping with tuberculosis and of plastic pleurisy with tuberculosis, but he believed that the frequency of this association had been exaggerated. He thought that in view of the well-grounded belief that in certain classes of animals, as well as in certain families of men, inflammation tends to linger, to produce accumulations which are prone to degeneration, and to *excite* local or general tuberculosis, it is more logical to conclude that in such cases as above mentioned there is at the outset a tainted constitution—a soil already sowed with the dormant seeds of disease waiting to be awakened to their active processes of destruction by the stimulation of an exciting cause. The more frequent the action of the exciting cause, the more certain is this dormant tendency to be aroused.

DR. J. H. MUSSER exhibited

TWO CASES OF CARCINOMA OF THE STOMACH.

Case I.—Scirrhus of the pylorus; general proliferation of the connective tissue; interstitial nephritis. Malignant disease of the pylorus and of the lesser curvature of the stomach was diagnosticated when the patient applied at the Medical Dispensary of the University Hospital, May 14, 1882, for treatment, on account of the physical signs especially, and of some points in the clinical history. Palpation and percussion revealed a firm, non-pulsatile, immovable, slightly painful tumor in the middle of the epigastric region, one inch to the left of the median line, about the size of a turkey egg. When lying down the abdomen was slightly scaphoid, but the left upper quarter was distended. A curved line extending downwards from the umbilicus to the flanks, represented the lower limit of this swelling, which was soft and resistant, tympanitic on percussion, and with care could be discerned as starting from the hard tumor in the epigastrium. In short, it was due to a distended stomach. Although the tumor was not in the position of the pylorus, and although the patient had never vomited, yet pyloric disease was determined upon because of the gastric distention. On account of absence of marked obstruction, the position and the occurrence of pain in the *lumbar* region, disease of the lesser curvature and the posterior wall was decided upon. The autopsy revealed that the malignant growth surrounded the stomach at the pyloric end, but being greater in extent in the lesser curvature. An adhesion to the left lobe of the liver explained the position of the tumor. The patient first noticed the localization of the disease in November, 1881, by the occurrence of pain in the epigastrium following a jar. She noticed that her health had failed three months before, and that menstruation had ceased six months previous to the epigastric pain. Note here the failure of health before any local evidences of disease, not even dyspeptic symptoms. She

was a widow, æt. 40 years, with one child, her health had always been very good, her circumstances moderate, and her habits exemplary. In addition to a constant burning pain increased by food, her appetite was poor, tongue pale, with enlarged papillæ; flatulency was marked, and the bowels constipated. She presented a sallow, cachectic appearance, was somewhat emaciated, extremely anæmic, with cardiac, arterial, and venous blood murmurs, and accentuated second-sound. She was under observation until her death, October 17, 1882. The pain and constipation were relieved by treatment, but the course was only downwards. In addition, I may note the cachexia became more marked, and the classical appearance of the face was wonderfully depicted—transverse and vertical lines on the forehead and semi circular lines around the mouth from the alæ of the nose to the chin, and vertical lines on the chin and lower lip. The hue of the countenance changed—growing darker and darker. This peculiar hue of the face Dr. Musser considered the most reliable symptom of approaching dissolution. It was noted one month before death. During the last two months of her illness she suffered much from soreness of the mouth and tongue without visible lesions; from burning in the fauces; difficulty of deglutition, acidity, vomiting taking place every third or fourth day of a clear acid fluid, coagulated milk bile-stained, and "coffee-ground material." A painless watery diarrhœa occurred frequently, with tarry masses. Œdema of the feet and ankles took place six weeks before death. The tumor grew in size and changed position, falling downwards. Three days before death it was noted to pulsate, was tender, and was three inches long, extending from the median line to the left on a level with the umbilicus. *Autopsy* (twelve hours after death).—Extreme emaciation; rigor mortis marked; œdema of feet. Heart slightly enlarged, the left ventricle walls 8¾ lines in thickness; heart weighed 7 ounces. Aorta 1 inch 1¾ lines in diameter, and slightly atheromatous. Deposits of fat along the septum were noted, and the muscular tissue itself was fatty. The stomach was in the position defined a few days before death, was greatly dilated, with the disease at the pyloric end extending along the lesser curvature four, along the greater curvature two, inches, and completely encircling the organ. The stomach walls became thickened, with much hypertrophied muscular coat, as they approached the diseased area. The internal surface of the tumor was flat, elliptical, and defined by an everted lip of varying thickness about 4 lines high. The surface was uneven, some nodules being half as thick. The most central portion presented distinct evidences of ulceration. The liver was rather larger than normal, seemed fatty, and was not indurated. The kidneys were small, hard, and the capsule peeled off with difficulty. Microscopic examination of the stomach, liver, and kidneys, Dr. W. E. Hughes assisting, showed abundant irregularly shaped epithelial cells packed closely in a fibrous stroma, but slightly developed in and containing numerous nuclei. Liver-cells fatty and pigmented. Proliferation of the connective tissue around the hepatic and portal veins was noted, many nuclei proving its recent origin. The kidney was markedly cirrhotic, the connective tissue being *not* of recent formation. Note the general proliferation of connective tissue in the organs. No albumen was detected during life in the urine, nor were any renal symptoms noted, yet there was undoubted interstitial nephritis belonging to the variety described by Gull, Sutton, and Mahomed. The malassimilation consequent upon the gastric lesion was the predisposing factor in the production of this general change.

Case II.—Scirrhus of the pylorus; symptoms simulating idiopathic anæmia. F. R., æt. 54, white, German, resident of a healthy locality, but much exposed as lumberman during the winter. Addicted to constant use of spirits, malt liquors, and tobacco. Had a fever of six weeks' duration at the age of sixteen years, and eight years ago some pulmonary inflammation. Never had malaria or syphilis. Does not know cause of mother's death; seven brothers and sisters healthy; father died of old age; his own three children living and healthy. Admitted to University Hospital December 20, 1878. During the previous winter had numerous gastric attacks, as shown by pain and loss of appetite. In the spring and summer he lost flesh and strength, and was subject to pain in the bowels and in the hepatic area, flatulence, pyrosis, and constipation, but never vomiting. On account of salivation in June, he became especially debilitated. At time of admission, weight 118 pounds, usual weight 170. Lies on left side, perfectly apathetic, with the physical and mental processes slow of action. Extremities cold, very anæmic, conjunctiva and mucous membrane very pale; sclerotics pearly white; complexion of a sallow, dirty hue. Palpitation of the heart, dyspnœa, and subjective ear-noises were noted. Temperature irregular; appetite poor; flatulence and pyrosis, pain and tenderness in epigastrium; no definable tumor, but a sense of induration. Hepatic and splenic areas of dulness normal. No venous hum. Heart sounds weak. Urine, sp. gr. 1018, neutral reaction, albumen one-sixth; no casts, bile, or sugar; phosphates not in excess. Blood, white corpuscles in excess, red greatly decreased in number. Ophthalmoscopic examination; slight retinitis. O. D. pallid; central artery dilated. Venous blood paler than usual. Absorption of choroidal epithelium, allowing choroidal circulation to be seen. Macula healthy; no hemorrhage throughout fundus. Both eyes present the same appearances. A low typhoid state soon developed, with diarrhœa and excessive flatulence. For three days prior to death vomiting occurred. He died December 30, 1882. *Autopsy.*—Stomach alone examined. It is to be regretted that the full record was lost. Stomach adherent to liver and transverse colon. Lesser curvature from pylorus half way to cardiac orifice, infiltrated with cancer, extending two inches over the anterior wall, and at the pylorus, encircling the organ. Pancreatic and biliary ducts pervious. Microscopically, the growth was found to be scirrhous carcinoma.

Remarks.—On account of the profound anæmia and the absence of tumor and vomiting, idiopathic anæmia was considered. The examination of the blood, and condition of the eye-ground, contra-indicated such a diagnosis. The normal size of liver and spleen, and the non-glandular involvement excluded leucocythemia. It is to be regretted that the exact numerical blood-count was not recorded. In this case the lesser curvature was very much involved, and a distinct tumor was absent; quite the opposite of Case I.

DR. A. P. BRUBAKER exhibited for Dr. H. LEAMAN, a

TUMOR OF BRAIN.

John J., æt. 53, laborer. When first seen, the patient was lying on his back, with head drawn backwards into the pillows, and complaining of stiffness and soreness in back of the neck. The mouth was widely opened and parched, and the breathing deep and heavy. He was in a semi-unconscious condition, from which, however, he could easily be aroused, but soon relapsed into his former state, which was attended by stertorous breathing. Speech and deglutition were both interfered with, but not abolished. There was involuntary passage of urine, but the bowels were constipated. Venereal ideas were excessive, but accompanied by complete impotence. Voluntary move-

ments of the extremities and also the power of coördination were considerably impaired. Pulse and temperature were normal. Liquid food was taken with difficulty. His condition had been as described four days previous to my first visit on September 4, 1882. The symptoms gradually increased and coma supervened, which ended in death, September 17, 1882. Following history was obtained from the family: Twenty-six years ago, the patient was confined to bed with "nervousness," for a period of two years, when he passed a calculus about the size of a date-seed; again a month later, another smaller one. His bladder continued to give him more or less trouble up to death. He had his clavicle broken nineteen years ago, but there was no injury to the head. About sixteen years ago he was suddenly seized while at work, with a severe headache, and became totally blind, which lasted for twenty-four hours. This was relieved by wet cups to back of the neck. From that time, he was subject to what they called "shaking spells"—when standing there would be a violent trembling of the knees and shaking of the arms. These attacks occurred about once a month, and occasionally three or four times a day. They increased from year to year in frequency and severity, and appeared to be excited by high winds and storms. In February, 1882, he was seized with paralysis, beginning in the left little finger, thence gradually extending to the ring and middle fingers, until the hand became powerless, but was able to move his arm. Then followed a numbness in the outer side of the left side, attended by impairment of the power of coördination, so that, on attempting to walk, he was compelled to run to keep from falling. He frequently fell in the street, and had to be carried home. Last February, loss of speech supervened, which lasted for one month; the patient then began to speak in monosyllables, after which speech gradually returned.

Autopsy.—Congestion of the entire brain. On removing it, four or five ounces of serum ran from the cranial cavity. Brain substance seemed to be normal throughout. In the right fissure of Sylvius was embedded a tumor about one inch and a half in diameter, which was almost entirely concealed from view by the convolutions. It rested upon the convolutions of the island of Reil, completely disorganizing them. The inferior extremities of the ascending frontal and parietal convolutions were normal. The upper surface of the temporo-sphenoidal lobe was somewhat disorganized. The tumor apparently sprang from the pia mater.

Report of the Committee on Morbid Growths.—A section made from the tumor presented by Dr. Brubaker, and examined microscopically, showed that the growth was tubercular. Its histological structure is seen to consist of fibrous tissue constituting a reticulum, the meshes of which are filled with lymphoid cells. These appearances are very distinct at the peripheral zone of the tumor, while the centre and inner zone are in a state of retrograde metamorphosis, presenting a very granular appearance, scarcely stained by the carmine. The bloodvessels are mostly obliterated, their lumen being filled with coagulated blood or granular *débris*.

DR. W. H. PARRISH exhibited specimens of

ENLARGED LYMPHATIC GLANDS.

I show five lymphatic glands removed from the axilla of a patient whose breast I amputated about nine months ago. The case was then reported to the Obstetrical Society and was published in THE MEDICAL NEWS of July 8, 1882. The specimen was referred to a committee, and Dr. Beates made a microscopical examination, and concluded that the growth was an adenoma that had undergone carcinomatous change. Of the enlarged glands presented this evening, three about the size of an almond were removed from the axilla, a fourth of smaller size from just below the clavicle, and the fifth from the side of the neck about an inch from the clavicle. The patient presents no cachexia. The specimens were referred to the Committee on Morbid Growths.

Dr. Parrish also exhibited

POLYPI FROM THE UTERINE CERVIX.

I also present this evening two small growths, each about the size of the last phalanx of the thumb, removed to-day with a wire écraseur. On Christmas eve, I saw for the first time a patient of French birth, a teacher, apparently about 35 years old. When I entered her room she was in a state of syncope from hemorrhage from the genitals. The hemorrhage had, however, ceased. With the application of hot wet-cloths over the front of the chest, and by hypodermic injections of whiskey, and aromatic spirits of ammonia, she in a few minutes revived so as to be able to tell me that she had not menstruated for three months, when suddenly bleeding began from the womb, and continued during the day with an exacerbation just before sending for me. As the patient's condition was evidently a critical one, I asked the direct question, if she had not had, or was not having an abortion. She said it was impossible. I then learned that she was single and 42 years old. A digital examination showed an intact hymen, and a substance in the vagina that at first touch felt very like an embryo of about three months. But I soon recognized that it was a growth attached to the lower part of the cervical canal, and that there was another distending the cervical canal. The latter felt still more like an embryo or ovum, and, in fact, in the absence of the one in the vagina might have at first misled me into thinking that the patient was aborting. Slight traction on it soon showed that it was attached. There was no return of the bleeding, and to-day, with the assistance of Dr. M. O'Hara, I removed both the growths with the wire, and without etherization or the use of a speculum. A remarkable feature of the patient's history is that she had always menstruated scanty, and at intervals of five or six weeks. Never before had she evinced a tendency to uterine hemorrhage. I am confident that the patient was not pregnant. I presume that, being virginal, she is approaching the menopause.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, December 26, 1882.

THE PRESIDENT, T. M. MARKOE, M.D., IN THE CHAIR.

INTESTINAL OBSTRUCTION.

DR. WEIR presented a specimen which illustrated intestinal obstruction occurring in the splenic flexure of the colon. The cause of the constriction was cancer. It was removed from the body of a woman 33 years of age, married, who entered the New York Hospital November 28, 1882, in the medical service. She had had complete obstruction for nine days previously, associated during the last few days with stercoraceous vomiting. The history was that she had had, some time last spring, an attack of intestinal obstruction, but not very severe, and from that time had suffered from attacks of constipation. The cause of the last obstruction could not be readily elicited, nor was any light thrown upon the subject by examination of the distended abdomen. It was recognized that there was great distention of certain coils of intestine, apparently in the site of the colon, though this could not be posi-

tively made out. Examination with the rectal tube showed that the gut could be penetrated to the depth of twenty-eight inches; this was accomplished several times when large enemata were administered. These latter also established the fact that about one hundred ounces of water could be received each time into the bowel without unduly distressing the patient, when placed in the knee-elbow position. Prior to her admission to the hospital, which was on a Tuesday, she had received a great deal of treatment, the exact nature of which could not be determined. At the invitation of the visiting physician, Dr. Draper, Dr. Weir saw the case on Wednesday afternoon, at which time the patient had a temperature of 102° F., pulse 120. These symptoms, together with the stercoraceous vomiting, the duration of the case, and the history of constipation of marked severity, led him to the conclusion that delay should not be continued much longer, and he therefore proposed a preliminary rectal examination. It was determined, however, to repeat the injections, and to wait until the following morning, and if no relief was obtained, to then resort to surgical interference. Relief was obtained, the injections bringing away a certain amount of fecal material, and the discharge was followed by two additional fecal evacuations of a creamy, muddy color and consistence. The vomiting ceased, and the general condition of the patient was so much improved as to encourage postponement of the proposed surgical interference. On Friday the symptoms of obstruction again appeared, except the vomiting. The abdomen became more distended than it had formerly been, the temperature rose higher, and there were nausea and cessation of fecal discharge and flatus. On Saturday Dr. Weir again saw the patient, and it was then learned that her general condition had very much depreciated within the last two days. Dr. Weir then proposed that rectal examination be made, which was assented to, and he then introduced his hand (of 9¼ inches circumference) slowly into the bowel, but was unable to carry it up beyond the upper rectal pouch; though he could carry one finger sufficiently far to enable him to sweep over the cæcal region. This, however, could not be recognized. He had proposed to perform a right lumbar colotomy if it had been determined by rectal exploration that the cæcum was distended; or, if unable to determine this point, to perform enterotomy. The patient, however, was so much prostrated by the ether and examination as to forbid a resort to further surgical procedures. She did not rally, as was hoped, but gradually sank, and died twenty-four hours afterward.

The autopsy revealed cancerous disease of the splenic flexure of the colon, so slightly perceptible externally as scarcely to be recognized. There was also a most minute secondary involvement of the liver. No injury had been done to the rectum by the manual exploration. The point of obstruction was twenty-three inches from the anus. The cæcum was apparently in the normal position, and not distended with fluid, but with air. To this point Dr. Weir wished to direct the attention of the surgeons, because he had heretofore felt considerable confidence that in cases of obscure intestinal obstruction a rectal exploration might be available as a means of diagnosis, and, by the recognition of a distended cæcum, might enable the surgeon to act with greater accuracy. In this instance such exploration had failed. The experience of Dr. Halstead, also, who would follow him in the presentation of a specimen, had led to the conclusion, that when the cæcum was distended with air it might not always be readily recognized by the touch. Another point to which he would like to ask attention was the diagnostic value of injections of water, and of the rectal tube. Heretofore he had placed much reliance upon the rectal tube, especially when the French black tube was used, because this latter more readily showed on withdrawal any twisting or sharp bending that might have taken place. In two instances he had proved by operation or by autopsy, that the site of the obstructions had been quite accurately determined in this manner. He had found some difficulty in carrying the tube beyond the sigmoid flexure in the cadaver in four recent trials by Dr. Peabody, but in the living subject it could be quite easily introduced. This difficulty could be easily understood because of the difference in the condition of the parts. During life the intestines yielded to pressure more readily than in the rigid cadaver, and perhaps the end of the tube itself produced spasmodic contraction, and the gut consequently changed its position or that of the end of the tube. As to the injection of fluids, there was a fallacy in that means of diagnosis, because the opening in the large intestine might admit the passage of fluid beyond it. That error was committed in one instance where there was a narrowing of the transverse colon, in which case he had performed right lumbar colotomy. Prior to the operation large quantities could be injected, with but little return. In one trial of a large turpentine enema, the matters vomited were strongly impregnated with the odor of the injection, showing that the ileocolic valve had been forced. A final word might be added which would bear also on the case to be subsequently narrated. It was that the pathologist of the hospital had, in remarking on the difficulty that would have been encountered in recognizing the site of obstruction by a laparotomy, said that in six autopsies of intestinal obstruction he had lately made, he believed that in nearly every one from a similar cause, relief would not have resulted from an operation.

CASE OF INTESTINAL INCARCERATION.

DR. W. S. HALSTEAD presented a specimen with the following history: Anna B., æt. 35; Irish; widow; well nourished; mother of eight children (youngest five years old); was admitted to Charity Hospital, December 16, 1882, complaining of constipation, colicky pains, distention of abdomen, and vomiting. She states that she has, since her infancy, been subject to similar, but less severe attacks, and remembers five previous ones distinctly—the last having occurred in March of this year. Heretofore, has been promptly relieved by "medicine," her symptoms having persisted on only one occasion for as long a time as two days, and their subsidence being always coincident with the escape of much flatus. Constipation had attracted patient's attention for several days prior to present seizure, which developed suddenly, about one week before admission, while she was drinking a cup of tea. Since then, nothing has passed from her bowels. She vomited on the 15th, for the first time, a little mucus, and has continued to eject, at intervals of several hours, frothy mucus and possibly bile, but at no time stercoraceous matter. House physician gave a cathartic soon after admission. My attention was called to the case on the following day, December 19. The recorded history being incomplete, I will recite it as accurately as possible from memory: Found patient tossing from side to side, moaning loudly, and apparently in great distress. Countenance slightly flushed, but not anxious. Respiration 27; pulse 98; temperature 98.5°. Thighs flexed, abdomen much distended and unevenly so, everywhere tympanitic, and in no one region especially sensitive to pressure.

Diagnosis.—Intestinal obstruction. Prescribed morphine, hypodermically, and directed that enemata, as large as possible, should be administered with the longest available tubes.

December 18.—Patient confident that she is conva-

lescing, assures us that she is free from pain, and has passed "wind" per anum. Respiration 22; pulse 104; temperature 98.5°. Cannot ascertain positively how much urine has been voided, but the nurse guesses four ounces in twelve hours. House physician states that hard œsophageal tube was introduced last evening to its fullest extent (about twenty inches), and that only one quart of fluid could be injected, which, when evacuated, brought with it mucus, but no gas, and not a trace of feces. Repeated the injection myself, with like result, and noticed that the tube was in several places most singularly bent and twisted.

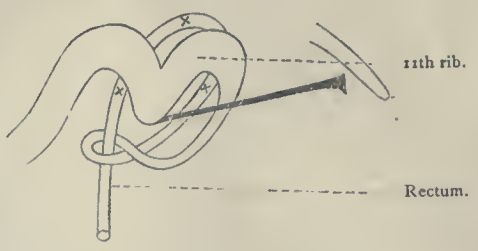
19th.—5 P. M. Pulse 120, and intermittent. 6 P. M. Patient anæsthetized. Assisted by Dr. Weir, proceeded to operate under carbolic acid spray (1–40). Incision in median line, from umbilicus to pubes. The peritoneum being divided, a small quantity of serous fluid escaped through the wound. The large intestine very much distended, and presenting a few small superficial ecchymoses, occupied the entire field of view, being folded upon itself longitudinally. The separation of the folds exposed the quite normal small intestine. After a somewhat prolonged and unsatisfactory search for the cause of the obstruction, which was evidently below the flexura linealis, there could be felt with the right hand a dense cylindrical band, about the size of one's little finger, very deeply situated, and stretching from near the promontory of the sacrum, obliquely upward and outward, to the parietes of the left hypochondrium, not far from the tip of the twelfth rib. The abdominal incision was then extended to within about two inches of the xiphoid cartilage. The obstructing cord being exposed, it could be seen to have its apparent origin from the transverse colon, and was divided between two stout catgut ligatures, which were passed around it by means of an aneurism needle. Below the band, and clearly compressed by it, were two tubes of large intestine, one of which filled with air as soon as released, while the other did not. The patient's condition was too bad to justify much further investigation, although it was evident that the disposition of the sigmoid flexure was most puzzling, and possibly offered another obstacle to the escape of intestinal contents. The distended colon, which had been protected throughout the operation by towels warmed in a solution of carbolic acid (1–40), was replaced without very much difficulty, and the wound united by a double row of sutures; the deep, of silver, included the peritoneum.

20th.—7 P. M. Patient has just died. Ever since the operation was observed by internes and nurses to have passed large quantities of gas from the bowels.

21st.—12 M. *Autopsy:* Quite firm union all along line of incision. Transverse colon slightly adherent to wound a little below umbilicus. Large intestine reached to fourth intercostal space on left side. Attached to the anterior surface of transverse colon at about its middle, and having its origin in the great omentum, was one portion of the divided bowel with its catgut ligature; the other part being intimately blended, and apparently continuous with the diaphragmatic peritoneum between the eleventh and twelfth ribs. The specimens before you show the attachments of the band.

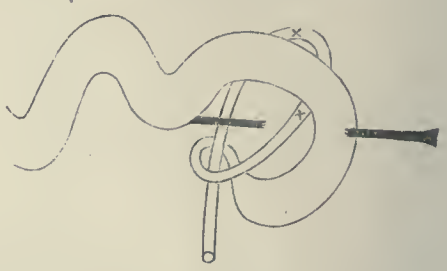
Figures 1 and 2, drawn in the light of the autopsy, are intended to illustrate what presumably existed before, and immediately after the operation. The xxx designate sigmoid flexure looped and twisted upon itself from right to left. The sigmoideo-rectal junction was sufficiently narrowed in the bight of the volvulus to prevent the ready escape of flatus per rectum. This constriction was evidently one of very long standing, and intensified somewhat by the underlying falciform fold of its mesocolon, which normally extends from the mesentery to the upper end of the rectum, and which, in this case, was unusually strong and prominent, with its concavity directed ventrally.

FIG. 1.



The *pathogenesis* may then have been: 1st. Non-inflammatory adhesion in intra- or early extra-uterine life of a considerable portion of large omentum (mesogastrium) to parietal peritoneum—adhesions of this nature being incidental to development, as urged by Sanger and verified by Soldt. 2d. Embarrassed growth of sigmoid flexure, giving rise to a rotation of same, which was permitted by the great length of the free

FIG. 2.



mesocolon at that early period, or by its coincident development. 3d. Narrowed sigmoideo-rectal junction; its growth having been somewhat restrained and its lumen reduced by pressure from without. 4th. Acute symptoms due, as suggested by Busch, to sudden distention of gut above and retraction of mucous membrane from below omental band, possibly preceded by further intrusion of descending colon under the site of constriction. I would suggest in similar cases the advisability of operating early, not only that the patient may survive the shock, but to anticipate a degree of hyperdistention of the intestine from which it can never recover. If there is reason to suspect the existence of a further source of obstruction, or if the tension within the distended gut cannot be decidedly relieved by simpler measures, I believe that laparocolostomy or enterostomy, as the conditions may dictate, to be indicated.

DR. SANDS remarked that, in Dr. Weir's case, the failure to recognize distention of the cæcum was probably due to the existence of a band at the upper part of the rectum, which prevented the hand of the operator from making the usual excursions. In one case he had been able easily to ascertain, by manual exploration of the rectum, a distended state of the cæcum, the patient having a stricture situated in the sigmoid flexure.

DR. WEIR remarked that he had heretofore regarded manual exploration of the rectum as a reliable means of determining whether or not the cæcum was distended.

DR. SANDS further remarked that in inserting the tube with the view of determining the presence of a stricture, it should be remembered that the constriction might be sufficiently close to cause abdominal ob-

struction, and yet not be so narrow as to prevent the passage of the tube. This condition was exemplified in a case he had already narrated to the Society, in which the ordinary black French tube was passed a distance of eighteen inches without encountering any obstruction. When the patient died a cancerous stricture of the rectum was found between six and seven inches from the anus, just large enough to allow the passage of the tube. Dr. Sands said that Simon had shown conclusively that it was impossible to pass an elastic tube beyond the splenic flexure of the colon, and that in cases where a great length of tube has been introduced the end of the tube had been arrested at the splenic flexure, the mesocolon allowing the tube to curve toward the right side.

DR. WEIR asked Dr. Sands concerning the value of exploration by means of the tube in any portion of the large intestine below the splenic flexure. He himself had already attached considerable value to such exploration if properly and repeatedly performed.

Dr. SANDS regarded such exploration as very valuable.

DR. GERSTER had observed a case somewhat similar to the one related by Dr. Halstead. In his case, however, he was able to detect at the operation the site of the obstruction. The patient was a boy, thirteen years of age, who had suffered from peritonitis eight weeks previous to his last sickness. The peritonitis had subsided under the ordinary plan of treatment, and the patient had recovered to such an extent as to be able to go to school. Two weeks afterward he was attacked by something which appeared like peritonitis. Morphine was administered, and he seemed to improve under the treatment so far as to permit the physician to attempt to evacuate the bowels by means of an enema. From the moment the enema was administered, very violent and alarming symptoms of intestinal obstruction developed. The chief reason why the effort was made to evacuate the bowels was the complaint of fulness of the abdomen, and entire absence of pain upon pressure. The symptoms which developed after the administration of the enema were intense vomiting and depression of the general system, with severe pain. The attending physician proposed to administer quicksilver to overcome the intestinal obstruction. A second physician was called, who found marked depression of the general system, feeble pulse, continued vomiting, and clammy perspiration despite the narcosis which had been produced by morphine; marked tympanitis also existed. The child, when aroused from his semi-comatose condition, always pointed to the left side of the belly as the seat of the pain. Dr. Gerster saw the patient in consultation, and proceeded to surgical interference for his relief. He made an incision which extended from the umbilicus almost to the symphysis pubis. Immediately upon opening the abdominal cavity the distended bowels rushed out through the incision, and filled it so full that it was impossible to form any adequate idea with reference to the position or condition of the abdominal contents. He extended the incision sufficiently far to admit of a full view of the abdominal contents, and then introduced his hand and felt most of the intestines to be movable, except one bunch consisting of four or five loops, which were anchored in the right iliac fossæ. Separating the loops of intestines constituting this bunch, he found they were bound down by a band one-fourth of an inch in width, which passed across one loop of the mass and formed the true cause of obstruction. Upon closer examination it was also ascertained that this apparent band was the vermiform appendix, which had evidently become attached to the abdominal wall during the previous attack of peritonitis. It had passed across a portion of the ileum about five inches from the cæcum, and its apex had become attached to the mesentery of the ileum upon the other side. The upper portions of the ileum and small intestine were intensely distended and hyperæmic, and the lower portion was pale and normal, as was also the large intestine. There was no evidence of acute peritonitis at the time of the operation. He applied a stout double catgut ligature to the band, or vermiform appendix, and divided it between the ligatures, whereupon the intestinal contents immediately rushed from the superior to the inferior portion of the ileum. Dr. Gerster then experienced great difficulty in attempting to replace the intestines within the abdominal cavity. Hoping to diminish their distended condition, he introduced the smallest size hypodermic needle, but the escape of gas was so slow that he withdrew the needle, intending to perform a large number of punctures, but when the needle was withdrawn, he noticed that one minute drop of intestinal contents followed, and appeared upon the external surface of the gut. He wiped the surface of the gut very carefully, and then introduced an elastic catheter into the bowel through the anus and administered an enema; his idea being that, the obstruction being removed, probably a portion of the intestinal contents could be removed in that way. The plan proved to be perfectly successful. The injection of hot water through the catheter brought away feces, and a large quantity of gas also escaped, followed by solid fecal masses. After the evacuation had occurred, the intestines collapsed so much that no serious difficulty was experienced in restoring them to the abdominal cavity, and the wound was closed. The abdominal cavity was not exposed longer than twenty-five minutes, but the patient died of collapse about eleven hours after the operation.

DR. HALSTEAD remarked that he also introduced a fine hypodermic needle into the distended intestines in his case, and observed precisely the same thing which Dr. Gerster had mentioned, namely, the exit of a small drop of intestinal fluid upon the withdrawal of the needle. Only a small amount of gas escaped, and that very slowly. Furthermore, Dr. Weir retained the intestines in position to a considerable extent by means of towels which had been dipped in warm, carbolized water, and after some manipulation they were returned to the abdominal cavity.

ENCYSTED NEEDLE IN THE LEG.

DR. POST presented a portion of a large needle enclosed in a cyst, which he had removed from a woman's leg about a hand's breadth above the internal malleolus. The patient was forty-five years of age, and gave the history that the portion of needle had been in this position during the last twenty-five years. The point of special interest in the specimen was that the needle was firmly encysted, the cyst, as exhibited in the specimen, almost completely surrounding it. At first it caused but slight irritation, and subsequently gave the patient no trouble whatever until a short time before she applied to him for relief. The needle was a large one, and the portion removed was two centimetres in length.

WEST PHILADELPHIA MEDICAL SOCIETY.

Stated Meeting, Monday, January 8, 1883.

S. S. STRYKER, M.D., PRESIDENT, IN THE CHAIR.

DR. R. M. MCCLELLAN read a short paper, entitled

NOTES ON THE NOVEMBER EPIDEMIC OF DIPHTHERIA.

The discussion was opened by a question from the PRESIDENT as to the experience of the members of the

Society in the treatment of diphtheria with large doses of calomel.

DR. BARTLESON said he had, in several cases, used twenty-grain doses every three hours, till two drachms had been taken. One of these was a case of membranous croup in a child seven years old. The child did not recover. Another was a child five years old, who got well.

DR. DULLES said he had first used calomel in large doses in the treatment of diphtheria last October. Soon after reading a strong recommendation of this method, he was called to an infant of six months, whose throat was full of membrane, so that it was hardly able to breathe, and could not nurse. He ordered five grains of calomel, to be given hourly, and in the intermediate half-hours, so as not to make black wash of the calomel, a teaspoonful of lime-water. After ten doses had been given, he saw the baby again, and to his great surprise found it very much better. The next day, he put his little patient upon sulphate of cinchonidia, and in a few days more she was entirely out of danger. After this, he had three more cases in the same row of houses, and all but one were treated similarly—the exception was an adult who had a very light attack. These did as well as the first case. In the case of the infant first mentioned, the calomel did not produce any purging; in the others it brought on three or four characteristic stools. With his limited experience, and with what was already on record, he was inclined to use again this method.

DR. J. H. MUSSER said that his own experience in the recent epidemic was that the cases were of a mild type, so that they got well almost without treatment. He used stimulants and spray of carbolic acid and lime-water. He had one case, however, which was of a different character. In this, a child, when first seen, had a sore throat like that of scarlet fever, with other symptoms of this disease, and, on the second day, a characteristic rash. Two days later, a diphtheritic membrane began to form in the fauces, and extended down into the larynx, and up into the nares. Apparently, this was a case of scarlatina, followed by diphtheria; or did the scarlatinal condition predispose to the infection with diphtheria? or were the two diseases developing at the same time? He had another case where all the pharyngeal symptoms of diphtheria were present, but in two days a scarlatinal eruption appeared, and the child died with the coma of scarlatina. As to the question of a distinction between diphtheria and membranous croup, he thought they were apt to be associated in the same epidemic, or one would follow the other. In all cases of membranous croup which he had seen, he could trace a connection with diphtheria, and therefore he thought membranous croup to be but a laryngeal diphtheria. Then, again, death is almost sure to take place from stenosis of the larynx before a septicæmia develops, and hence before the contagious period of the disease has arrived, thereby preventing the infection of other members of a family.

DR. M. B. MUSSER said, in reference to the relation between diphtheria and membranous croup, that he had never seen two cases of membranous croup in the same family at the same time; while in diphtheria, where one case occurs there are usually others similarly affected, or, at least, they have sympathetic sore throat. In regard to treatment, he had some time ago seen a case in which Dr. Meigs, whom he had called in consultation, suggested the use of the hyposulphite of calcium. Other remedies had been used without apparent success, but when this was tried, a most decided improvement took place within twenty-four or forty-eight hours. Since then he has had equally good results from its use. He uses, in nearly all cases, quinine by suppositories, and the tincture of the chloride of iron and chlorate of potash, together with stimulants. Locally he applies the persulphate of iron, dissolved in an equal quantity of glycerine.

DR. BARTLESON said that he used boracic acid in a solution of two drachms in half an ounce of glycerine and half an ounce of water. After its employment he has seen the membrane melt away. For internal treatment he uses iron and potash, adding hydrochloric acid, so as to give the mixture a little free chlorine.

DR. MULLEN had seen ten cases of diphtheria in one family; five were severe, and five were not. As a diagnostic point, he called attention to a peculiar and very offensive odor about the breath and flatus. In treatment he uses locally lime water, the vapor of slaking lime, and insufflations of sulphur, together with a general tonic and stimulant course. He has seen dropsy follow diphtheria as well as scarlatina.

DR. ROCKWELL thought there was a difference between membranous croup and diphtheria. In the former he had seen patients die very soon of asphyxia without adynamia. In diphtheria he had seen admirable results from the local application of lime-water by means of the atomizer.

DR. STRYKER inquired whether, in the sore throat of scarlet fever, there was any destruction of tissue with the formation of membrane.

DR. J. H. MUSSER replied that in such cases there was often sloughy tissue, which, however, was different in appearance from the membrane of diphtheria. He thought there were cases where diphtheria existed as a complication of scarlatina.

DR. ANDERSON said he had had, last year, a case of this sort. A child had had scarlet fever, and diphtheria followed. A week or so later, a brother of this child had apparently scarlet fever, with characteristic rash, and no membrane in the throat. But three or four days later a diphtheritic membrane formed, with high continued fever, which, after convalescence, was followed by most persistent paralysis. He inquired whether paralysis was more apt to follow mild or severe attacks of diphtheria?

DR. J. H. MUSSER inquired of Dr. Dulles whether the occurrence of the rash in diphtheria had any analogy to the occurrence of a scarlatinal rash after surgical operations.

DR. DULLES said that after surgical operations there is not infrequently a scarlatinal eruption, which is usually mild, and in regard to the etiology of which nothing is certainly known. It is probably a coincidence, and yet may be hastened in its development by the operation. A similar rash is observed in the diphtheria of puerperal women, which may also be considered analogous. But the frequent occurrence of rash, like that of scarlatina, with well-pronounced diphtheria, and of a sore throat, like that of diphtheria in unmistakable cases of scarlet fever, suggests something more than coincidence. It suggests a relationship between these two diseases, which is all the more probable when we consider how generally they are associated as epidemics.

CORRESPONDENCE.

OVARIOTOMY STATISTICS.

To the Editor of THE MEDICAL NEWS:

DEAR SIR: Last summer I wrote to Mr. Knowsley Thornton, of London, begging him to be so kind as to furnish me with an account of the latest statistics of ovariotomy in Great Britain, including his own, for the new edition of my *Surgery*. When his communication reached me, it was too late for me to avail myself

of his kindness, and I therefore wrote to him at once, asking permission to publish the statistics in THE MEDICAL NEWS, to which he promptly consented. As showing the latest triumphs of ovariotomy, these figures cannot fail to be of deep interest to the ovariotomists of this country. Mr. Thornton has great reason to be satisfied with his own results, reflecting, as they do, great credit upon his methods and operative skill.

I am, very truly, yours,

S. D. GROSS.

ELEVENTH AND WALNUT STREETS, January 17, 1883.

22 PORTMAN STREET, LONDON W., November 30, 1882.

DEAR DR. GROSS: I fear you will think I have forgotten my promise. At last I send you the statistics. I have found it very difficult to get them. I can get nothing later as to Clay's and Dr. Keith's, only up to October, 1881. The others are almost to date.

	Cases.	Recovered.	Died.	Mortality per cent.
Dr. Clay,[1] of Manchester,	93	64	29	31.11
Mr. Spencer Wells,[2] .	1088	847	241	22.15
Dr. Keith,[3] . . .	381	340	41	10.76
Mr. Knowsley Thornton,[4]	328	293	35	10.67
Mr. Lawson Tait,[5] . .	226	199	27	11.94

Dr. Peaslee (page 276) credits Mr. Clay with two hundred and fifty cases; recovered, 182; died, 68; mortality, 27.2. I have not been able to verify these results, and therefore have not given them in the above table. The discussion in the *British Medical Journal*, in 1880, failed to elicit any statement from Clay himself *as to results*. He then said that he had performed four hundred before he ceased to operate. I think, under any circumstances, his results should hardly be given in comparison with those of Wells, Keith, Tait, and myself, as ours are thoroughly authenticated by published tables; Clay's never have been.

I think my own mortality answers your question as to the value of the spray. I did not know until I began to look up the matter for you that I actually have got slightly the lead.

Trusting that, though late, the figures may be of some use to you, believe me, with much esteem,

Very truly yours,

J. KNOWSLEY THORNTON.

DR. GROSS, PHILADELPHIA.

THE EARTH DRESSING.

To the Editor of THE MEDICAL NEWS.

SIR: The editorial article in your issue of December 30th, "Earth Dressing in Germany" gives an incorrect notion of the material used in dressing wounds at Prof. Esmarch's clinic, and I beg to be permitted to call attention to it. The writer describes the material as "earth," and "earth-mould," and claims for Dr. Addinell Hewson the credit of having introduced it as a surgical dressing. But it is quite a different thing. Dr. Hewson used "the yellow subsoil" "from deep diggings" (to quote from his monograph) after drying and sifting it; whereas the dressing introduced by Neuber into Esmarch's practice is the ordinary peat ("Torf"), which is generally used for fuel in North Germany. After being dried it is ground up into a coarse granular and fibrous mass, which is enclosed in bags of gauze, and sprinkled with some antiseptic solution (5 per cent. carbolic acid, or corrosive sublimate 1 to 1,000), or mixed with 2½ per cent. of iodoform, and applied to wounds by means of "crinoline" bandages.

I had the opportunity in May, last, of observing the application of this dressing and its gratifying results at Esmarch's clinic; and have, since July, employed it frequently at the New York, St. Luke's, and Chambers Street Hospitals in this city. It has proven the most satisfactory and cheapest form of antiseptic dressing that I have tried; and in six years I have used the carbolized gauze and jute, the salicylated and borated cotton and "antiseptic irrigation."

The peat may be obtained from Mr. J. Neuber, P. O. box 1410, New York City. Two hundred kilogrammes cost, delivered here, about $25. This quantity fills a case a little larger than the average dry-goods box, and will be sufficient for an active surgical service of fifty beds for the period of three or four months.

Respectfully yours,

WILLIAM T. BULL, M.D.

2 EAST THIRTY-THIRD STREET,
NEW YORK, January 15, 1882.

[1] Mr. John Clay's translation of Kiwisch's Clinical Lectures, 1860.

[2] Tables in book and personal communication to me on November 29, 1882.

[3] Letter to Mr. Wells, October 17, 1881.

[4] My own are down to date.

[5] Paper published in Birmingham Medical Review and British Medical Journal. Total number of operations down to August 5, 1882.

NEWS ITEMS.

BROOKLYN.

(*From our Special Correspondent.*)

THE MEDICAL SOCIETY OF KINGS COUNTY held its sixty-second annual meeting on the 16th inst., and the following were elected as officers of the Society for the ensuing year: *President*, G. G. Hopkins, M.D.; *Vice-President*, F. H. Colton, M.D.; *Secretary*, R. M. Wyckoff, M.D.; *Treasurer*, J. R. Vanderveer, M.D.; *Librarian*, T. R. French, M.D.; *Censors*, Drs. A. Hutchins, C. Jewett, J. S. Wight, B. F. Westbrook, and G. R. Fowler. Two *delegates* to the State Medical Society, Drs. E. N. Chapman and L. S. Pilcher.

A lively discussion arose over a resolution offered by Dr. Skene, rescinding the vote of the November meeting, instructing the delegates of this Society to the American Medical Association and to the State Society to vote against the so-called "new" Code. This resolution was carried, under a call for the yeas and nays, by a vote of 49 against 26. This action leaves the delegates uninstructed upon the Code question, but does not affect the vote formerly taken expressing the Society's sentiment of opposition to the new Code.

THE STAFF OF THE KINGS COUNTY HOSPITAL has been somewhat unsettled lately. The Commissioners of Charities made some appointments, December 23, to the consulting staff and then constituted that staff a visiting staff. On January 20, however, the matter was reconsidered on the request of members of the old consulting staff, and it was ordered that the former status should be restored.

BUFFALO.

(*From our Special Correspondent.*)

THE ERIE COUNTY (N. Y.) MEDICAL SOCIETY AND THE NEW YORK CODE.—At the annual meeting of the Erie County Medical Society, held on the 8th inst., the following resolution was adopted:

"*Resolved*, That the Erie County Medical Society disapproves the action of the State Medical Society, at its last meeting, in adopting the report of the special committee revising the Code of Medical Ethics."

CHICAGO.

(From our Special Correspondent.)

COUNTY HOSPITAL.—Chicago is having much trouble with its great public hospital, the Cook County Hospital. The Board of County Commissioners, under whose control it is placed by law, has been in more or less of a turmoil for many months among themselves regarding its management. Meanwhile the county is spending nearly or quite a quarter of a million dollars in erecting two additional brick pavilions and a central executive building, which will be ready for occupancy some time next summer.

The troubles of the hospital have not, however, been confined wholly to the secular management, for within two years there have been three successive medical boards. As soon as a member of the medical staff has any difficulty with the management, and the fact reaches the official ears of the Board of Commissioners, the remedy for the difficulty—the Board seems to practise a specialty in the use of a single remedy—appears to be to turn out the whole corps of doctors, and the remedy is promptly administered. Such frequent changes are a little disturbing to the regularity of clinics, and somewhat to their efficiency, although it is always found that the staff are ready and glad to give clinical instruction to students.

For the outlook for medical teaching at this point there is satisfaction in the fact that the county hospital is increasing in importance, and in the number of cases treated every year, and the further fact that there are now so many medical colleges near it that it must be largely used in the years to come as a centre for clinical instruction. It now has nearly four hundred patients constantly; this number cannot be expected to decrease so long as the present rapid growth of the city continues. This growth is now about thirty thousand annually. The municipal census of 1882 (required by law to be taken every two years) showed a population of sixty thousand six hundred over the government census of 1880.

The County Hospital occupies a large block of land—over twelve acres. There are four medical colleges so near the hospital grounds that they are simply separated from it by a street—they "surround" it. Three belong to the regular profession, and two of them are for the education of men—the "Rush" and "Physicians and Surgeons'." One, the "Woman's," is for the education of women exclusively. The fourth school belongs to the persuasion of minute pellets.

MONTREAL.

(From our Special Correspondent.)

MCGILL COLLEGE.—The students of the first and second years have petitioned the Faculty and Board of Governors for the removal of Dr. Wright, the Professor of Materia Medica, on the plea that his lectures are diffuse and unpractical. They resolved to absent themselves from his lectures after Christmas, but a compromise has been made, and the trouble temporarily arranged for the session.

PARASITES IN CANADIAN PORK.—Mr. A. W. Clement examined at the city abattoirs one thousand hogs, and found four trichinous, seventy-six "measley," and thirty-seven with echinococci. The proportion infested with trichinæ is considerably smaller than in American hogs, as shown by the Chicago and Boston examinations. Trichinosis is a very rare disease in Canada; only twelve cases have been recognized, three in Hamilton, Ont., in 1868, and nine in Montreal, in 1870. Four post-mortem and dissecting-room cases have been recorded.

THE HEALTH OF MASSACHUSETTS.—The annual report of the State Board of Health, Lunacy, and Charity, has just been submitted to the Legislature. The report states that Massachusetts is more exposed to smallpox than any other State, and that in 1881–82 the disease appeared in about thirty cities; but the deaths from this disease in 1882 were less than in Chicago in one week. The year 1882 was one of average health, and no disease can be said to have prevailed excessively. Malarial fever has not appeared in so many of the towns east of the Connecticut as in the previous years, but in the western part of the State it seems to have been more prevalent than ever. The number of i people in the State is at least 5,100, a net increase of about 200. During the year 52,416 immigrants arrived in the State by sea. Probably 30,000 of these remained in the State, and as many more came from other quarters.

GUITEAU'S REMAINS.—The Rev. Dr. Hicks, the spiritual adviser of Guiteau, has executed a legal instrument transferring to Surgeon-General C. H. Crane, U. S. A., all his right and title to Guiteau's body. The paper recites the clause of the will by which Guiteau bequeathed his body to Dr. Hicks, and it bears evidence of acknowledgment before a Justice of the Peace. In reply to inquiries Surgeon-General Crane said he was unable at present to give any information with regard to the final disposition of the assassin's remains.

FIRE IN AN INSANE ASYLUM.—A fire in the Kings County Hospital for Incurable Insane, in Flatbush, L. I., endangered the lives of fifty lunatics on Thursday morning of last week. A night nurse while making his rounds at 5 A. M., found smoke pouring from the sitting-room on the second floor into the hall. He gave the alarm, summoning Medical Superintendent Woodside and six nurses. Half of them set at work to put out the fire and the others to remove the insane patients in the ward. An alarm was also sent to the Flatbush Fire Department. The hose in the building was put to use, and, there being plenty of water, the fire was speedily subdued, and the firemen were not needed before their arrival. Much difficulty was experienced in getting the patients out of their rooms to a place of safety. Many had to be carried out in the arms of the nurses. The fire is believed to have been caused by the accumulation of refuse around the radiator used to heat the room where it broke out.

HONORS TO PROF. VON PETTENKOFER.—PROF. VON PETTENKOFER has received from the King of Bavaria, a patent of hereditary nobility in recognition of his invaluable contributions to the science of hygiene.

DR. H. B. SANDS, of New York, was elected a corresponding member of the Société de Chirurgie, of Paris, at its annual meeting on the 8th instant.

AUTOPSY OF GAMBETTA.—The post-mortem examination revealed a contraction of the ileo-cæcal valve, the result of an old inflammation of the bowel and extensive purulent infiltration around the cæcum and ascending colon, with traces of recent peritonitis, thus confirming the ante-mortem diagnosis of perityphlitis and pericolitis. Under the circumstances a surgical operation would have been unavailing.

LONG ISLAND COLLEGE HOSPITAL.—The opening exercises of the twenty-fourth session of the Long Island College Hospital took place last Tuesday evening. The annual address was delivered by Health

Commissioner Raymond. At the close of the exercises a crayon portrait, handsomely framed, of Dr. S. G. Armor, Dean of the Faculty, was presented to Dr. Armor, in behalf of the students, by Mr. J. W. Whitney, of the senior class.

COMPLIMENT TO DR. JAMES E. REEVES, OF WHEELING, W. VA.—At a meeting of the West Virginia State Board of Health, held on the 13th inst., the following preamble and resolutions were adopted:

"*Whereas*, This Board has received many very high compliments from distinguished sources for the manner in which it has performed its difficult labors—notably, for its efforts to elevate the standard of medical education in West Virginia; and,

"*Whereas*, It is always just and proper to acknowledge credit to whom credit is due; therefore,

"*Resolved*, That this Board is fully sensible of the eminent services of its secretary, Dr. James E. Reeves, to whom belongs, in the main, the credit of directing its successful labors, and in all things upholding its good name, by his faithful energies and labors alike for the State and the medical profession."

The Board also adopted, unanimously, resolutions urging upon Congress the importance of continuing and furthering the work of the National Board of Health.

MEDICAL EDUCATION IN PHILADELPHIA.—*The Continent* for January 17, 1883, contains an interesting historical sketch of the progress of medical education in Philadelphia.

FLORIDA AS A HEALTH RESORT.—DR. R. J. LEVIS contributes an article to the current number of *The Continent*, on the Gulf Coast of Florida, in which he points out its advantages as a health resort, particularly for subjects of pulmonary disease.

DR. DUHRING'S WORK ON DISEASES OF THE SKIN.—A very laudatory review of the French translation of Dr. Duhring's treatise on diseases of the skin has just appeared in the *Annales de Dermatologie et de Syphilographie* for December 25, 1882.

PREVENTIVE VACCINATION IN CHARBON.—At the meeting of the French Academy of Sciences held Dec. 18, 1882, M. PASTEUR read a paper giving the results accomplished during the past year in the department of the Eure-et-Loir by the farmers who have practically applied his method of inoculating live stock as a preventive of disease. The number of sheep vaccinated within the year has been 79,392. For the last ten years the average annual loss from liver-rot has been 7,327, or 9.41 per cent. Since the introduction of vaccination this loss has been reduced to 518, or 0.65 per cent. Among the flocks which have been only partially vaccinated, there were 2,308 sheep vaccinated and 1,659 not, and the loss among these was only eight for the 2,308 vaccinated sheep, or 0.4 per cent., while it was sixty among the 1,659 unvaccinated sheep—3.9 per cent. It is worthy of note that these sheep were brought from different parts of the department, and that the vaccinated and unvaccinated ones were all fed and treated in the same way, and subjected to absolutely identical influences. The veterinarians of the Eure-et-Loir have vaccinated during the year 4,562 head of cattle, and there have been only eleven deaths, the rate of mortality being thus reduced from 7.03 per cent., at which it stood a year ago, to 0.24 per cent. Horses were not vaccinated to so general an extent as cattle and sheep, on account of the swellings which follow vaccination in these animals; but of the 524 so treated only three died. M. Pasteur emphasizes the importance of these results, and adds that in the last six weeks 13,000 sheep, 3,500 cattle, and 20 horses have been vaccinated, without a single accident having occurred in these 16,520 animals.—*Gaz. Méd. de Paris*, Dec. 30, 1882.

ADULTERATION OF QUININE IN PARIS.—M. LABORDE stated, at the Société de Biologie (*Gaz. des Hôp.*, December 19th), that the quinine used in the Paris hospitals contains sometimes as much as forty-three per cent. of cinchonine, and that the two substances differ much in their actions. He has proved this by experiments of injecting both substances hypodermically in guinea-pigs, when death is produced much more rapidly by the adulterated than by pure quinine. Some *pharmaciens*, he observes, under the mistaken idea that the action of both substances is alike, substitute, either partly or wholly, cinchonine for quinine. This is very important to be known, especially in typhoid fever, which predisposes to some of the accidents resembling those produced experimentally by cinchonine.—*Med. Times and Gaz.*, Dec. 30, 1882.

PROCEEDINGS OF THE ILLINOIS STATE BOARD OF HEALTH.—The annual meeting of the Illinois State Board of Health was held January 11, 1883. Dr. Rauch presented the quarterly report of the secretary, from which we make the following extracts:

Smallpox.—With the advent of cold weather a few scattering cases of smallpox have appeared in the State, but without creating excitement or manifesting any tendency to become epidemic. At three points in Cook County, and in Aurora, Kane County, the infection is attributed to Chicago. At Marshall, in Clark County, the disease was brought from Cincinnati, and at Cambridge, in Henry County, it was brought from Pennsylvania. So far as the history of these cases has been ascertained, it is found that the victims were, in every instance, either unvaccinated or not vaccinated since infancy or childhood.

There have been no cases among immigrants during the quarter—none, in fact, since the single case in the early part of June last, soon after the sanitary inspection of immigrants was begun. Strenuous efforts have been made to secure the continuance of these inspections, or, at least, their prompt resumption at the opening of the immigrant season. The secretary thinks it is demonstrated—from the history of smallpox in Chicago during the past thirty-two years; from the consensus of statements of leading health officials concerning the origin and spread of the recent epidemic; and from the results of the operations of the Immigrant-inspection Service—

1. That the immigrant is a prime factor in the origin and continuance of smallpox in the United States.

2. That State and local boards of health, acting independently, cannot suppress the disease, when once introduced, so long as the influx of unprotected immigrants continues.

3. That the immigrant-inspection system, in addition to furnishing a practical mode of coöperation by the various State and local boards of health, has proved entirely adequate to remedying the defects arising from want of international quarantine laws and of uniformity in the administration of our own maritime and boundary quarantines.

Immigrant-inspection Service.—My final report to the Secretary of the National Board of Health, in which are summarized the operations of the Service in the Western district during the season, shows that a total of 115,057 immigrants were inspected in the district during June 1 and December 31, 1882. Of this number, 57,302 were found to have been satisfactorily vaccinated before sailing or during the voyage, and 3,127

were found to have had smallpox—making about 53 per cent. of the total number protected. There were 28,408 of the remainder vaccinated or revaccinated after arrival and before reaching this district; and 21,618 similarly treated by the Western inspectors, leaving 4,602 unaccounted for, including those whom it was deemed inadvisable to vaccinate.

At the close of August, I made a table of the results obtained up to that time. There had then been an aggregate of 63,962 persons inspected, of whom it was found that 54 per cent. were imperfectly or entirely unprotected against smallpox on arrival, and that only 22 per cent. were vaccinated on shipboard. These figures have been changed by the pressure and influence of the Inspection Service upon the steamship companies and their surgeons, so that, for the whole season, the percentage of "susceptible" was reduced to 47, while the proportion of ship-vaccinations was increased to 29, in the hundred.

This latter figure (29 per cent.) represents an actual increase of fully 42,000 vaccinations secured on shipboard by this means, during the latter, as compared with the first half of the season; and indicates the increasing value, efficiency, and influence of the Service, both directly and indirectly, at the time when its operations were suspended.

Prior to the preliminary steps taken to secure this Service (including the notification of Dr. Smith, Health Officer of the port of New York, to the steamship companies last spring), vaccinations on shipboard—except in rare instances—were confined to the occasions of the actual appearance of smallpox cases on board. So that, as a matter of fact, an aggregate of about 174,000 vaccinations on shipboard have been obtained among the arrivals at all ports, simply as a result of the existence of the Service, and independently of those performed by the inspectors after arrival.

Medical Education.—The exposure of the Boston Bellevue Medical College, and its consequent disruption, of which the members have already been advised, have been followed by some unlooked-for developments. As a result of the correspondence carried on from this office, the most convincing proof was secured that the so-called "college" sold diplomas and degrees to individuals grossly ignorant of any medical knowledge, and either with or without attendance upon its alleged course of instruction. Its officers were arrested for using the United States mails for fraudulent purposes, and, on trial, admitted all that was charged against them, except violation of the postal laws. To this charge they pleaded that they were legally incorporated, and were empowered by the laws of Massachusetts to issue diplomas and confer degrees without any restriction as to course of study or professional attainments. The United States Commissioner held the plea to be valid, and dismissed the case with the following remarks:

"The State has authorized this college to issue degrees, and it has been done according to legal right. . . . The law makes the faculty of the college the sole judges of eligibility of applicants for diplomas. There is no legal restriction, no legal requirement. *If the faculty choose to issue degrees to incompetent persons, the laws of Massachusetts authorize it.* This is, therefore, not a scheme to defraud under the statute. The defendants are dismissed."

Since this decision was rendered, that is, within a fortnight, the "American University of Boston," president, Dr. Buchanan (familiar name in this connection), and the "First Medical College of the American Health Society," located at Boston, have been incorporated, and Dr. Alfred Booth, the first president and one of the incorporators of the "Boston Bellevue," has given notice of his intention to start the "Excelsior Medical College."

Thirty-one individuals have been detected in falsely swearing to be graduates of foreign universities, their pretensions exposed, and the impostors driven from the State through the Act to Regulate the Practice of Medicine.

School Vaccination.—The school population of Illinois is now quite well protected against smallpox.

National Board of Health.—The following preamble and resolution were unanimously adopted:

Whereas, The Act of Congress, appoved June 2, 1879, by which the National Board of Health is charged with the duty of coöperating with and aiding State and local boards of health in the enforcement of their rules and regulations to prevent the introduction of contagious and infectious diseases into the United States, and into one State from another, will expire by limitation on the 1st of June, proximo; and

Whereas, The said National Board of Health has discharged this duty with so much of success, honesty of purpose and regard to economy, as to conclusively demonstrate the value of a national agency for the protection of the public health; therefore, be it

Resolved, That the Illinois State Board of Health earnestly urges upon the Senators and Representatives from this State to obtain, during the present session, the legislation necessary to secure an extension of said act, pending the creation of a permanent national health organization—such legislation to include a provision whereby the unexpended balances of the original appropriations may be reappropriated and made immediately available for the purposes of said Act.

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending January 13, 1883, indicate that diphtheria, neuralgia, rheumatism, and scarlet fever have increased, and that consumption has considerably decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during the week ending January 13, and since, at 21 places, scarlet fever at 17 places, and measles at 14 places. Smallpox was reported at Detroit, January 13.

OBITUARY RECORD.—In New York, on the 23d inst., GEORGE M. BEARD, M.D., aged 43 years. Dr. Beard was born in Montville, Conn.; he received his classical education at Yale, and graduated in medicine at the College of Physicians and Surgeons, New York, in 1866. He was one of the originators of the National Association for the Protection of the Insane and the Prevention of Insanity, and was a frequent contributor to the literature of the diseases of the mind and nervous system. His death is said to have been due to pneumonia. He leaves a wife and daughter.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 15 TO JANUARY 22, 1883.

SPENCER, WILLIAM G., *Captain and Assistant Surgeon.*—The leave of absence on surgeon's certificate of disability, granted September 20, 1882, is extended three months on surgeon's certificate of disability.—*Par. 4, S. O. 16, A. G. O., Jan.* 19, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

ON INTRA-LARYNGEAL GROWTHS.

A Clinical Lecture.

BY CLINTON WAGNER, M.D.,

PROFESSOR OF DISEASES OF THE NOSE AND THROAT, NEW YORK POST-GRADUATE MEDICAL SCHOOL; SURGEON-IN-CHIEF TO THE METROPOLITAN THROAT HOSPITAL.

GENTLEMEN: In the pre-laryngoscopic period the presence of laryngeal growths was rarely recognized, owing to the want of means of making an accurate diagnosis. The first case of which we have any record is that of Koderik, in 1759. Brauers, Ryland, Ehrman, Rokitansky, and Horace Green have all published reports of cases before the introduction of the laryngoscope into general practice. But the most interesting of the several treatises are those of Ehrman, in 1850, who published a record of all the well-authenticated cases, twenty-six in number, all of which proved fatal except three. In 1859, Dr. Horace Green, of New York, in an able monograph, gives the entire number of recorded cases as forty; thirty-seven of which resulted fatally. Seven or eight of this number occurred in this country; four in his own practice.

The symptoms show themselves in an alteration of voice, or disturbance of the function of respiration, the act of swallowing, and in some cases cough and pain.

The alteration of the voice may range from slight huskiness to complete aphonia. It will depend upon the size of the growth and its location. If sessile and upon the superior surface of the cord, the voice may undergo no change whatever. If it is attached to the free edge, or overlaps the free edge of either of the cords sufficiently to prevent approximation, there will be complete aphonia. If attached by a pedicle to the under surface of the cord, it may produce aphonia by being thrown upwards and between the cords during phonation or attempted phonation, approximation will be interfered with, and no voice will be produced. The voice sometimes has a peculiar vibratory tone or metallic ring which the ear of the skilled laryngoscopist may frequently detect at once and suspect the presence of a growth, even before making the examination with the mirror. If the growth is in either of the ventricles of the larynx or attached to the ventricular bands, voice may not be interfered with.

Breathing is interfered with in those cases in which the growth has attained sufficient size to lessen materially the calibre of the larynx. The location of the growth may have much to do with the disturbance of respiration. If in the upper part of the larynx on or above the ventricular bands, it is less apt to produce dyspnœa than if lower down and in the glottis proper. A growth which does not ordinarily produce much distress in breathing may seriously impair it if the patient should catch cold, producing congestion of the mucous membrane to any extent. Inspiration is more labored than expiration. If the growth is attached to either of the cords, the respiration is very stridulous and attacks of spasm of the glottis more or less frequent.

The act of swallowing is interfered with should the growth be of large size and attached to the epiglottis or to the posterior wall of the larynx, or overhanging or adjacent to the pharynx.

Cough is not always present, and when it is the growth will probably be found attached by a pedicle and interfering with the movements of the glottis.

Pain is rarely present, and when felt, the growth is usually of malignant character.

A succession of colds which keep up a chronic congestion of the mucous membrane—chronic laryngeal catarrh—is one of the most common causes. Syphilis and tuberculosis have no agency in the production of new formations in the larynx. The professional use, or rather the abuse, of the voice may be assigned as a cause of laryngeal polypi. Persons between the ages of 35 and 50 are most prone to new formations in the larynx. They are sometimes congenital. Dr. Eddis reports a case of an infant that died thirty-seven hours after birth from strangulation produced by a laryngeal polypus. Dr. Causit thinks they are most frequent in infancy, while Dr. Bruns reports a case occurring in a subject seventy-four years old. In my own practice, my youngest case was a boy five years old, from whom I removed a large papilloma; my oldest case, a man sixty-three.

Varieties of growth: benign and malignant.

Benign: papillomata, fibromata, myxomata, cystomata, lipomata, angiomata.

Malignant: sarcomata, epitheliomata.

Papillomata are most frequently met with of the several forms of laryngeal polypi or growths. They are generally multiple, and vary in color from a whitish-pink to a deep red. If thoroughly removed, they are not apt to recur. Sometimes a mere crushing with the forceps will suffice to produce a sloughing or disintegration of what remains. It is claimed that this variety may recur or reappear as a malignant variety if not thoroughly removed. I have had several cases in my own practice which somewhat support this theory. A case whom you have all seen at the Metropolitan Throat Hospital, first came to me in January, 1881, nearly two years ago. At that time there was a growth about the size of a large pea on the right cord, near the anterior commissure. I regarded it as a papilloma, and suggested the removal by the forceps, which could have been done at that time without difficulty. The patient declined, and sought treatment elsewhere. Twelve months later he again consulted me, at which time the whole box of the larynx was almost completely filled with growth. Several large pieces were removed by means of the forceps, but as the growth was found to extend downwards below the cricoid cartilage, and as dyspnœa was becoming more urgent each day, tracheotomy and thyrotomy were performed, the growth removed, and the patient discharged in a few weeks from the hospital. The tumor was submitted to Dr. Heitzman, of this city, for examination, who pronounced it a benign growth of the variety known as papilloma. But in his report he stated that it had grown from a highly inflamed base, and if it recurred it would most likely come as a malignant growth. A few months later, in June, just before I left for Europe, the patient came to me, suffering from great dyspnœa. A large amount of growth had reappeared in the larynx, on the right side. During my absence a canula was introduced into his trachea by a surgeon in Brooklyn; and upon my return I again operated. This time I removed an enormous amount of growth. It involved the whole of the right side of the larynx, and extended below the cricoid cartilage. I found it necessary to remove also several portions of the thyroid cartilage, in order to

secure thorough extirpation of the growth. Its attachments were destroyed by the galvano-cautery. A portion of the tumor which was submitted to Dr. Heitzman for microscopic examination, was pronounced to be epithelioma; thus supporting the theory that a perfectly benign growth may degenerate into a malignant variety, and also confirming the opinion of the microscopist in this particular case, that if a recurrence took place, it would come in a malignant form. Fourteen weeks have now passed since my last operation, and not the slightest trace of the growth can be seen. It is to be hoped, for the patient's sake, that my friend Dr. Heitzman has committed an error in his diagnosis of the tumor. I might add another interesting feature of this case; ossification of the thyroid had taken place, and also of the right arytenoid. In performing the first operation, in using the curette upon the anterior surface of the right arytenoid, I probably destroyed the mucous membrane over the arytenoid by the force it was necessary to use, and also dislocated it from its cricoid attachment. Sloughing must have supervened, for about three weeks after the operation, during a severe fit of coughing, the right arytenoid, completely ossified, was expelled through the mouth. The specimen which I exhibit to you is that of the ossified arytenoid.

The specimen which I exhibit to you in this bottle is a papilloma removed from a child five years of age. The little fellow was admitted into the Metropolitan Throat Hospital about four and a half years ago. He was suffering from alarming dyspnœa, with frequent attacks of spasm of the glottis. An examination revealed a large papilloma attached to the right cord and almost completely filling the box of the larynx, and between the cords posteriorly could be distinctly seen what appeared to be a web of membrane stretched from cord to cord. The child was much reduced in flesh and strength, and thyrotomy was at once decided upon. Tracheotomy was first performed, and immediately afterwards thyrotomy. This growth was removed, the false membrane cut away with the scissors, and the patient put to bed. The membrane was probably the result of an attack of croup which he had had some time before. The boy recovered perfectly and gained rapidly in strength and flesh, and was discharged five weeks after the operation. I saw him some two years later; he was in perfect health and there had been no recurrence of the growth.

Fibromata are the next in frequency. We have the hard and soft variety, the former the most common. Their growth is very slow. They are usually attached by a pedicle, and arise from the submucous cellular tissue or perichondrium.

The specimen which I exhibit to you was removed from a stout, muscular man, aged thirty-six, by occupation a butcher. This growth was attached by a pedicle to the under surface of the right cord at about its junction with the middle and anterior thirds. During quiet breathing, the tumor would drop below the cords and almost disappear from view, but during the act of phonation it was forced upwards and lay upon the surface of the cords or between them. I made several unsuccessful efforts to seize this tumor during quiet respiration. Finally I directed him to make the "ah" sound loudly and forcibly, during which I rapidly introduced the forceps, and caught and severed the entire growth.

The specimen in this bottle is a small fibroma which I removed several weeks ago from a gentleman at my office. It was attached to the free edge of the left cord at its junction with the middle and anterior thirds. His voice was a squeaking falsetto. Immediately upon removing the polypus he recovered his natural deep bass voice.

Myxomata are very rare. Very few cases are on record. Mackenzie, in his extensive practice, has not met with a single case. In the *Archives of Laryngology* for January, 1881, I reported a very interesting case occurring in my practice. The tumor was pronounced by Dr. Heitzman to be a true myxoma, a growth rarely found in the larynx,

Cystomata are of more frequent occurrence. They are usually found upon the epiglottis, sometimes upon the true cords. A cystic growth on the epiglottis which occurred at my clinic at the Metropolitan Throat Hospital, was removed without difficulty by the forceps.

Lipomata, or fatty tumors. There is but one case on record. It occurred in the practice of Dr. Bruns and grew by pedicle from the ventricle, and was of a yellowish-white color.

Angiomata, or vascular growths, are very rare. They resemble a papilloma except in color, which is black. They are very benign in character and not apt to recur if thoroughly removed.

In malignant growths (carcinoma and sarcoma) there is usually more pain, the growth is more rapid in its development, dysphagia and dyspnœa, especially the former, are more marked than in the benign varieties. In the later stages the neighboring submaxillary glands become involved, and after ulceration has taken place there is fetor of the breath, and the expectoration is mingled with a muco-purulent secretion. In the early stages of the malignant form of growth we cannot always diagnosticate them as such. If we could, the operation for removal of the larynx could be performed at a period when the chances of success would become much greater. In my lecture upon syphilis and tuberculosis of the larynx, I mentioned that it was sometimes extremely difficult to differentiate in a given case between syphilis, tuberculosis, and malignant disease of the larynx; even the most experienced may be at a loss to decide. A man called at my office for treatment during my absence in Europe in the summer of 1880, and consulted Dr. Howland, who had charge of my practice. The whole of the anterior surface of the epiglottis was covered with an angry-looking, nodulated, fungoid vegetation, On the left side near the free edge there was slight ulceration, which showed a disposition to extend. The man was fifty-three years of age and had had primary syphilis some thirty years before. The trouble was regarded by Dr. Howland as specific, and he was given iodide of potassium. The ulceration rapidly increased under this drug, which fact, together with the peculiar nodulated appearance of the growth unlike any case of tertiary syphilis that had ever come under my observation, satisfied me that the disease was malignant. I removed the epiglottis by the sub-hyoidean incision and submitted the growth to Dr. Heitzman for microscopical examination, who pronounced it cancer of the epiglottis, of the variety termed epithelioma. The disease returned, and the man died nine months after the operation. This case presents another point of interest, from its being the first operation for the removal of the entire epiglottis of which we have any record. A report of the case was published in the *Medical Record*, May 21, 1881.

Sarcomata of the larynx are not as frequently met with as epitheliomata. They resemble in appearance very much the papillomata, and vary in color from a deep red to yellow, or the pink of the mucous membrane. This specimen, which I have called sarcoma, was so pronounced by an eminent microscopist of this city. Another gentleman of equal eminence, to whom the specimen was submitted, called it a papilloma. And still another an *epithelioma-papilloma*. It began as a small sessile growth on the right cord, the greater portion of which I removed with the forceps. The patient returned to me in about six months, at which time his

larynx presented the appearance already described. I performed tracheotomy, followed immediately by thyrotomy, and removed the growth thoroughly, applying the galvano-cautery. Two months later I was compelled to perform another thyrotomy for the removal of the tumor, which had reappeared. I proposed to him at that time to remove the entire larynx. He objected, and in all I did thyrotomy seven times. He lived two years after the performance of the first. I might add that several months before the end, he expressed a willingness to submit to the removal of the entire larynx, but at that time owing to the engorgement of the cervical glands and the extension of the disease to the trachea, the operation was not considered feasible.

Surgery has taught us that whenever a tumor or new formation interferes with the function of an organ, our duty is to remove the growth if the operation is at all practicable. If the laryngoscope had done nothing more than to enable us to diagnosticate the presence of intra-laryngeal growths, it would rank as one of the greatest of boons to modern surgery. I stated that Dr. Horace Green, in his monograph published in 1859, gave the entire number of recorded cases as forty, thirty-seven of which proved fatal. With the aid the laryngoscope has given us, there is now no reason why a case of benign growth should not be removed, and the functions of the larynx wholly restored before life has become in the slightest degree endangered. Growths may be removed by the endo-laryngeal or the extra-laryngeal method. The former consists of removal by evulsion, by cutting, or crushing. I usually employ Mackenzie's forceps, which I here exhibit to you. They are cutting and crushing, and the blades open either antero-posteriorly or laterally. There are a number of sizes, and about fourteen or fifteen forceps comprise the entire set. I wish to divest this operation (by evulsion) of the manifold risks and dangers supposed to be incurred by the patient and exaggerated by the advocates of so-called conservative surgery. It is an operation attended with little or no danger, and which any one who can introduce a brush properly into the larynx, guided by the mirror, can perform. *Preliminary training in the majority of cases is quite unnecessary.* In Vienna it is the custom, or at least it was some years ago when I was in that city, to submit the patient to training. That is, a laryngeal sound of silver or other metal neatly covered with leather was introduced into the larynx and brought into contact with the growth for many days before the professor attempted the operation. About twelve hours just preceding the operation, applications with the brush of a strong solution of morphia, alternating with chloroform, were made about every half hour. And with all this preparation, I have seen the attempt to remove the growth fail and deferred for another sitting. Bromides internally and locally are also given, and produce an anæsthesia, or rather an insensibility, of the larynx. I hold that if a brush can be introduced into the larynx, the forceps may also be.

I rarely submit the patient to any preliminary training other than introducing the mirror for from five to ten minutes for several days, provided there is irritability of the pharynx. I have frequently removed growths at the first and only introduction of the forceps. My method of introducing them is as follows: I take the largest size laryngeal mirror in my left hand, and in the right hand a pair of forceps adapted, as far as possible, to the particular case in hand. That is, as the distance from the arch of the tongue to the larynx will, of course, vary in different individuals, I employ a pair of forceps longer or shorter in relation to that distance. After introducing them into the mouth, and having the point well back of the epiglottis, I carry them as quickly as possible into the larynx. In other words, I try to surprise the organ; that is, to anticipate the spasm which surely follows the introduction of foreign bodies. It is not always possible to watch the course of the forceps after they have entered, but you must have well in your mind's eye the exact location of the growth. If it is anterior, near the commissure, you direct your forceps to that point. If posterior, you carry your forceps to that part; and so, whether it is on the right or left cord, you give the proper direction. With a little practice—and delicacy of touch can always be acquired by practice—you will be enabled to tell whether or not you have the growth within the grasp of your forceps. Force should never be employed, as it is wholly unnecessary. The instrument is introduced closed and opened after it has reached the glottis. The larger the growth the more easily will removal be accomplished. In regard to the evil results which it is asserted are apt to follow the introduction of the forceps, such as perichondritis, necrosis of the cartilages, ulceration, paralysis, I have never met with such accidents. But I can easily understand how such consequences may be brought about. The forceps should never be introduced for more than three or four times at one sitting, and then, failing to seize the growth, the patient should be sent away, and no further attempt made for several days. A congestion of the mucous membrane may be produced, and a too frequent introduction of the forceps while in that condition may lead to unpleasant results. For that reason I recommend you to be in no haste in the treatment of these cases. I have never seen any good results follow the application of astringents or caustics to intra-laryngeal growths. I have no doubt that many of them could be dissipated by the stronger caustics, such as nitric acid, London paste, caustic potash, chromic acid, etc., but it is impossible to localize the effects of these agents, and consequently their introduction into the larynx is out of the question. The milder caustics, such as nitrate of silver, zinc, iron, or copper salts, are useless. If a patient consults you for hoarseness, and you discover a small growth upon one of his cords and you rely upon brush applications for its removal, you will surely fail. Your assurance to him that the growth will not be apt to increase in size, will not be apt to affect his general health, or interfere with his respiration, will not satisfy him. He will probably seek a surgeon who has the skill to remove it, and you, through your want of confidence in your skill, will lose the treatment of the case.

The extra-laryngeal method, thyrotomy, should never be performed except in those cases in which respiration is seriously impaired. And even in those cases where the growth almost entirely fills the box of the larynx, every effort should be made to remove it *per vias naturales*. It is a capital operation, and is always attended with more or less risk of life. The operation is easy of performance except in those cases in which ossification of the thyroid has taken place, and this usually occurs after forty-five years of age. If tracheotomy is considered necessary previous to thyrotomy in a given case, it should be followed immediately by thyrotomy, and not wait as recommended by some authorities for several weeks. You will only be subjecting your patient to the dangers incurred from two capital operations instead of one, as is the case when both are performed at the same time. Until my last operation for dividing the ossified thyroid I had always used the Hay's saw, but the operation is tedious owing to the difficulty of fixing or steadying the larynx, and it is by no means easy to keep it in the exact median line. In the case of a man upon whom I operated several weeks ago, at the Metropolitan Throat Hospital, I employed a small file-cut

wheel made to revolve by means of the dental engine. I divided the ossified thyroid in an incredibly short space of time, the line of incision was very clean, and the superiority of this instrument over the Hay's or small metacarpal saw, upon which we have been compelled to rely, was clearly demonstrated. I have here a number of instruments; forceps of various kinds, cutting and crushing; as well as a guillotine or circular knife, such as are employed by the throat specialists in Vienna. I consider them inferior in every way to those of Mackenzie, and for that reason I never employ them in my operations. Prof. Rossbach, of Würtzburg, has suggested an operation which consists of introducing a sharp-pointed narrow knife through the median line of the thyroid into the larynx, and then by aid of the mirror introduced into the patient's mouth any growth which may be upon the vocal cords is to be cut off. This operation has been described as a simple one attended with no hemorrhage, and we are told that the patient is unconscious of the presence of the knife in the larynx, and neither retching nor coughing is liable to be excited. If the patient is unconscious of the presence of the knife, the larynx certainly will not be. You will surely have spasm of the glottis, and more or less hemorrhage; it will be utterly impossible to hold the mirror *in situ* from the retching which will be produced; and, in addition to all this, if the knife is permitted to remain in the larynx during the spasm, I can readily conceive that the posterior wall of the larynx and the anterior wall of the pharynx may be cut through. I have never attempted this operation, and never shall, as I consider it wholly impracticable.

ORIGINAL ARTICLES.

NOTE ON A CASE OF ECZEMA OF THE FACE IN AN INFANT.

BY CHARLES W. DULLES, M.D.,
SURGICAL REGISTRAR TO THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

ABOUT a year ago, H. G., an infant, eight months old, fat, but white looking, was brought to me suffering with eczema of the face, having a large patch on each cheek, and one on the chin. The disease was of the papulo-squamous type, the surface being rough, somewhat elevated in spots, and of a red or brownish-red tinge, according to the temperature of the air. It had now lasted some months, and the child's parents had little hope of having a cure effected. With this in view, I gave a guarded prognosis, and tried my hand at the little boy. I worked away from March 2 to April 28—nearly two months—with diluted iodine ointment, zinc ointment, white precipitate ointment, cod-liver oil and calomel and zinc ointment mixed, locally; and internally, with castor oil and rhubarb, till I had the bowels in fine condition. But all accomplished only temporary and trifling results. At this juncture, one day, with the child before me, it occurred to me to try the effect of removing the cuticle and stimulating the deeper layers of the skin with the tincture of iodine. I at once put this idea into execution, making, on April 28, a limited experiment on the chin, to begin with. This worked well, and I then, on May 8, tried it on the chin and one cheek. These both did well, and on May 26 I painted all three places with equally happy effect. After each application of the iodine desquamation occurred, and the improvement was marked. By June 5 the face was cured, and there has been no recurrence of the disorder in the six months which have since elapsed.

I have been led to narrate this case because I find, on inquiry of some of my friends who are specialists in dermatology, that the line of treatment last employed, which was novel to me, is also novel to them. I am told that a similar method is not uncommonly followed in obstinate, long-established, and indurated eczemas of adults, but that it has not been recognized as applicable to eczemas in very young persons.

It certainly worked admirably in the present case, getting rid of the red, dry, rough and scaly patches on both cheeks and chin, which had been of the most disfiguring character. And when next I encounter like conditions, I shall not postpone having recourse to it till after I have tried the methods usually recommended, but use it at first.

One of my friends, an experienced specialist, to whom I spoke of the treatment while I was employing it, said he would hesitate to use the tincture of iodine undiluted on the face of an infant, for fear it would prove too irritating. This fear, however, was not realized in my case. The remedy did no harm, was easy to apply, required no change of dressings or trouble on the part of the mother, and it was followed by a prompt and permanent cure.

THE REACTION OF DEGENERATION.

BY G. BETTON MASSEY, M.D.,
ELECTRO-THERAPEUTIST AND ASSISTANT PHYSICIAN TO THE PHILADELPHIA ORTHOPÆDIC HOSPITAL AND INFIRMARY FOR NERVOUS DISEASES.

THE value of electricity as an aid in the differential diagnosis of various forms of paralysis is quite considerable, and is largely owing to recent investigations into the behavior of muscular tissue under the influence of the poles of a galvanic battery. Under certain well-determined conditions a variation in this response is clearly and readily found, and points unerringly to a change that can have no higher seat than the trophic centre of the affected muscle, thus immediately excluding all possibility of a cerebral origin of the malady, and, as we shall see directly, being of still further aid in narrowing down our inquiry into the probable seat of the paralysis.

This "reaction of degeneration" of muscular tissue to galvanism was first observed by Brenner, and afterwards by Erb, the latter making quite an elaborate study of the subject, and first suggesting the name by which it is now known.

During several years past I have been much interested in an attempt to verify these statements of Prof. Erb in the abundance of material to be found at the electric clinics of the Infirmary. The result has been a complete confirmation of the existence of the reaction, and of its claims upon the attention of the profession.

In obtaining this reaction a reasonable amount of dexterity and circumspection is necessary, but its

recognition is by no means sufficiently difficult to deter the most inexperienced manipulator from the attempt. The hazy description of the phenemenon by the specialists who have mentioned it, is, therefore, much matter for wonder.

In this article nothing will be said of the action of the faradic current; it is also assumed that the reader will understand that the galvanic current is only to be taken into consideration at the opening and closing of the circuit, as it is then only, under ordinary circumstances, that any contraction of muscle occurs.

First, it is to be clearly understood that the reaction of nerve trunks and of muscular tissue should be sharply distinguished. Quantitative changes of excitability (increase or diminution of the response without change of the normal formula given below) occur alike in nerves and muscles, but it is in muscles only that these peculiar changes of a qualitative character occur; and it is because we cannot eliminate the intra-muscular nerve twigs from a participation in the polarity induced in the surrounding muscular tissue by the superimposed pole that we sometimes find it difficult to detect the slighter degrees of qualitative change—the true behavior of the muscle being masked, as it were, by the greater excitability of the nervous tissue. To thus confine the influence of the pole whose action we wish to test to the tissue of the muscle chiefly, it is evident that some attention should be paid to topographical anatomy. Similar considerations should also guide us in selecting a position for the opposite, indifferent, pole. It is usually recommended by those who have written on the subject to place the indifferent pole on the sternum; this, however, is unwise beyond the fact of its rather painful character, as contractions of most of the muscles of the limb are apt to be produced by the current in its course from the chest towards the opposite pole. Experience has suggested to the writer that it is far better to select a contiguous tendinous or bony spot as the position of the indifferent pole. In the examination of the tibialis anticus muscle, for instance, the patella forms a good point of departure, as also for the quadriceps extensor. Some attention to the point of departure is absolutely essential to a correct examination.

Having placed one well-moistened electrode over the muscle to be tested, and the other in some carefully selected point of departure, it next becomes necessary to properly close and open the circuit. For this purpose nothing is in any way comparable to a pedal rheotome, a simple mechanism worked by the foot; it is, in fact, a necessity whenever the services of an assistant cannot be obtained, as a steady application of the electrodes is essential in many delicate cases—even the slightest movement produced by the working of the hand-current-breaker being confusing. If the pedal rheotome also contains a commutator, worked by the foot, for changing the poles while still *in situ*, its handiness will be greatly increased. The clockwork current-breakers usually furnished by instrument makers are totally unfit for diagnostic purposes, since the current should be completely under the control of the operator.

The normal reaction of the galvanic current in muscle is as follows: With a medium strength of current (15 to 20 sulpho-chromic cells, or 25 to 35 bluestone cells, in accordance with the temporary condition of the battery), there is a decided contraction at the closure of the circuit with the kathode, or negative pole, on the muscle. On changing the poles by means of the commutator, thus bringing the anode, or positive pole, over the muscle, we obtain a slight contraction at the closure. There are no contractions at the opening of the circuit with either pole. In other words, the normal condition presents a stronger kathodal closing contraction and a weaker anodal closing contraction. This, simply stated, is the key to the whole matter; but, simple and easily verified as it is, it yet has been more than once overlooked or misinterpreted by electro-therapeutists. Erb[1] states that with an intermediate grade of current the kathode causes a strong contraction on closure, but none on opening the circuit. "The anode, on the other hand, causes feeble contraction, both when the current is closed and when it is opened, the degree of contraction being nearly the same in both cases, though sometimes the one and sometimes the other may be somewhat the stronger, or may show itself more promptly." Whether the muscular tissue of an American, under the stimulus of anelectrotonus, acts differently from the Teutonic fibre or not I cannot say; but I am certain that not even our German-American citizens present that sort of anodal response. I can only explain his statement by the supposition that he paid but little attention to the point of departure. Dr. Bartholow[2] has fallen into even a more serious error when he states that the anode causes contractions chiefly on opening the circuit. If he had but tested the thenar eminence of his left hand, a moment would have sufficed to show him his error. The mistaken estimate of the action of the anode by both authors is really unaccountable, as it is clearly evident to any experimenter that the anodal closing contraction is much stronger always than the anodal opening contraction—in fact, that it is obtained usually by a strength of current that will show no motion whatever at the opening.

To repeat: with a medium current we obtain good kathodal closing contraction, slight anodal closing contraction, and no motion whatever at either kathodal opening or anodal opening.

The great strength of current required to bring the opening contractions in health makes the operation a painful one, and is apt to precipitate volitional interference with the electro-motility; but, to make the statement complete, it may be added that in increasing the current strength to the point of giving great pain, it is said that we may obtain an anodal opening contraction, and with a still higher strength, kathodal opening contraction.

Now the "Reaction of Degeneration" consists

[1] Ziemssen's Cyclop., vol. xi. p. 273.
[2] Bartholow's Medical Electricity, p. 117.

merely in a more or less perfect reversal of the above formula. The anodal closure then causes a stronger contraction than the kathodal closure. This is readily demonstrated in all typical cases. A less degree of degeneration may be present, however, and shown in but a slight increase of anodal closing over kathodal closing contraction. A still less degree may be present and indicated by an equality of the two closing contractions, and yet this would still be an unerring sign of the presence of the qualitative change in question.

In recording the notes of cases at the Infirmary, it has been found very convenient to use the formula recommended by Erb, which consists in the use of the initials of the German words employed to describe the reaction. Thus the formula of the normal reaction, kathodal closure: stronger contraction, anodal closure: weaker contraction, may be recorded by the letters Ka.S.Z.; An.Sz.; Ka. and An. representing kathode and anode respectively, S. representing *Schliessung*, closure, and Z. *Zuckung*, contraction. The relative strength of the contraction is best represented by a large or small Z. Other symbols that may possibly be needed are, O., *Oeffnung*, opening of circuit, and Te., *Tetany*, or prolonged contraction. There are at least two good reasons why the initials of the German words should be retained in English formulas rather than the translated initials, viz., the necessity we would be under to assign different meanings to the same letter in the translation; and, secondly, the established usage of the German formula in European scientific works, including some British authors.

It has been found by Erb that this change in the response of the muscle to galvanism is accompanied by, and coincident with, a change in the nutrition of the muscular elements themselves. After section of a motor or mixed nerve, an atrophy of the muscular fibres immediately sets in. It may be seen during the course of the second week. It consists in a narrowing of the fibres, which may possibly reduce them to one-half their width in five or six weeks. The transverse striæ become less distinct, there is a notable increase in the muscle nuclei, and it is even said that a chemical change may be demonstrated in the contractile substance. It is at this time (from two to six weeks after the paralysis) that the reaction of degeneration may be found at its height. It is accompanied by an absolute quantitative increase of galvanic response, and total absence of farado-contractility. From this time on the degenerative response lessens in amount and distinctness, in accordance with the relative increase of connective tissue, until finally the trophic control is reëstablished over the part, with a gradually returning normal reaction; or, in hopeless cases, a sclerotic atrophy, representing the débris of muscle, presents a final and permanent obstacle to any and all forms of motility. Thus the difficulty at times experienced in obtaining the degenerative response in cases where it should be found may be due to the lateness of the stage of paralysis at the time of examination. In such cases an earlier examination would have undoubtedly disclosed the change.

As to the diagnostic value of this sign, we have already some positive data. It is to be found in all cases of traumatic paralysis depending on injuries to nerve trunks. In fact, all peripheral paralyses of nerves due to neuritis, or other lesions acting upon nerves after their exit from the brain or spinal cord, such as compression by tumors, extravasation of blood, etc., will show the abnormal response in the early stages. Of this class may be mentioned facial paralysis, the various artisans' palsies, and local spasms due to neuritis from over-use, such as scrivener's palsy or cramp, telegrapher's palsy or cramp, seamstresses' palsy, pianist's palsy, etc., together with the worst forms of paralysis from compression, as, for instance, the musculo-spiral paralysis not infrequently contracted by drunkards while sleeping with the head resting on the arm. It occurs also in lead palsy, and in infantile paralysis.

With the exception of the last-mentioned two affections, all examples of its presence are strictly confined to diseases in which considerable anatomical changes exist in the nerves. In reference to the exceptions—lead paralysis and infantile spinal paralysis (*i. e.*, polio-myelitis anterior acuta of either children or adults) it may be mentioned that they consist essentially of disease of both the gray matter of the cord and of the muscles themselves—the relative importance of which is still under discussion among pathologists—and are accompanied by great trophic disturbance. With these exceptions, therefore, the occurrence of the reaction of degeneration points most positively to a peripheral disease of the nerve trunks, or of the conductors of trophic influence within the cord, and excludes the possibility of brain disease, thus, in most cases, having important bearings upon our prognosis.

In view of the above facts, together with the statement that the reaction is normal in progressive muscular atrophy as long as any muscular tissue is left, I would suggest that the true explanation of the phenomenon is closely connected with a study of the conductors of trophic influence and the effect of interference with or abolition of their functions as conductors.

Some practical hints bearing upon treatment are the following: In all cases of paralysis of motility showing this qualitative change there is more or less total loss of response to faradism. Galvanism should therefore be preferred to faradism as a therapeutic agent. Since also the anode or positive pole becomes the most active, it should be given the choice of position in applications to the muscles.

1632 ARCH STREET.

HOSPITAL NOTES.

BOSTON CITY HOSPITAL.

(Service of W. C. B. FIFIELD, M.D.)

FRACTURE OF THE OS CALCIS OF EACH FOOT; DEATH FROM EMBOLISM ON THE TWELFTH DAY; AUTOPSY.

(Reported by ROYAL WHITMAN, M.D., House Surgeon.)

THE patient, a robust German, was brought to the hospital September 19, 1882. While being drawn up a shaft in a bucket, the rope broke, and he fell a distance of about eighteen feet, striking upon his feet.

Examination showed the following injuries: Several incised wounds of the face. Upon the inner aspect of the right ankle, immediately below the malleolus, was an incised wound about two inches in length. Upon the introduction of the finger, a compound, comminuted fracture of the inner aspect of the os calcis, immediately below the articulation with the astragalus, was detected, the cancellous structure of the bone being exposed, but not injured to any extent. Several small fragments of bone were removed, and the wound was dressed with carbolized gauze.

The left ankle and lower leg were swollen, discolored, and tender on pressure. There was indistinct crepitus about the ankle, and apparently a slight outward displacement of the foot. No change in the contour of the heel was discovered, and a positive diagnosis as to the position of the fracture was not made, though it was thought to be a fracture of the outer malleolus. The leg was placed in a fracture-box, and hot fomentations applied to the ankle.

During the following week the patient progressed favorably. The swelling about the left ankle persisted, and several blebs formed upon the leg. There was a slight amount of suppuration about the compound fracture of the right foot, but no pain or swelling. On the afternoon of October 20, the swelling of the left ankle having subsided, a roller plaster bandage was applied.

In about one-half hour after its application the house surgeon was called, and found the patient in a state of extreme cyanosis, pulse rapid, feeble and irregular, expression anxious, face covered with cold perspiration, respiration sixty to the minute, and gasping in character. The patient complained of great pain in the cardiac region, and said that he was dying. Air entered the lungs freely. The foot of the bed was raised and subcutaneous injections of brandy and ether were given, but without effect. The patient rapidly grew worse, and died in about fifteen minutes after the first symptom.

Autopsy (eighteen hours after death).—There was a fracture of the inner aspect of the right os calcis, as has been described, an area about three-fourths of an inch in diameter of the cancellous structure of the bone being exposed. No injury of the neighboring bones or soft parts.

The left foot was then examined, and the os calcis was found to be completely smashed. The superior surface, articulating with the astragalus, was firmly impacted into the surface to which the tendo Achillis is attached. This portion of the bone was also fractured in various directions, though the fragments were not separated. The remainder of the bone was broken into several fragments. The surrounding soft parts were considerably lacerated and the adjacent veins filled with thrombi. No other bones of the foot or leg were injured.

The lungs were then examined and the main pulmonary arteries were found to be almost completely occluded by thrombi.

REMARKS.—Fracture of the os calcis of both feet is an extremely rare accident; but two cases of it having been reported—one by Malgaigne, and the other by Voillemier.

Malgaigne speaks of the difficulty in making a diagnosis of the injury, and says that it is most often mistaken for fracture of the fibula on account of the pain and swelling about the ankle. Recovery is usually slow, and considerable disability often results.

Embolism, as a cause of death in fractures, is not mentioned in the prominent works on surgery. The only mention of this complication that I am able to find is as follows:

"Azam, of Bordeaux, first wrote upon this subject in 1865. He has demonstrated that thrombosis, which may also accompany a great variety of injuries and inflammatory diseases of the limbs, is particularly liable to occur about fractures of the leg. The intimate relations which exist between the bones and the tibial and peroneal veins explain the frequency of its occurrence. Embolism, the results of which are so serious, is a consequence of thrombosis, and is of much more common occurrence than is generally believed. In all ages, surgeons have noticed cases of sudden death, most frequently occurring after fractures of the lower leg. They have explained these deaths by pretended serous or nervous apoplexies, convenient and pompous explanations, but devoid of sense; and had Azam done nothing more than to demonstrate in a single case the stupidity of such explanations, he would have accomplished something, for the discovery of a positive fact is never in vain, but always of practical importance."—*Noveau dictionnaire de Medecine et de chirurgie.*

MEDICAL PROGRESS.

LIGATURE OF THE BROAD LIGAMENTS AS A SUBSTITUTE FOR CASTRATION IN CASES OF UTERINE FIBROMYOMA.—DR. GIOVANI COSENTINA reports the case of a married women aged 36, with an interstitial fibroid tumor of the uterus, who suffered from an almost continuous uterine hemorrhage, and in whom all the ordinary remedies had been tried without success. The case seemed to be a suitable one for the removal of the ovaries, the operation for which was decided upon, and even commenced. From the difficulty in detaching the ovaries, which were adherent to the uterine walls, and with the idea that perhaps the hemorrhage might be caused by the immense congestion of the veins of the ligament, the right broad ligament and Fallopian tube were ligated. The wound in the abdomen healed readily, and the woman was discharged. Two months later she returned, and it was found that the tumor had greatly reduced in size, and the hemorrhages had diminished in frequency and severity.—*Journ. de Méd. de Paris*, December 23, 1882.

THE MICRO-ORGANISM OF WHOOPING-COUGH.—DR. CARL BURGER describes an organism which he has found in the sputa of patients with whooping-cough, which are so constant in their appearance in this disease, while never to be seen under other circumstances, that he believes there must be some etiological reason for their presence, particularly since the intensity of the disease depends upon the number of the organisms present. He has not yet reported the results of the culture-experiments with which he is at present occupied.

These organisms are readily detected by simple staining with watery aniline solutions, and may be prepared in the same manner as employed by Koch in the case of the bacillus tuberculosis. Dr. Burger describes them as ovoidal rods, about twice as long as broad, with a slight constriction around their middle; occasionally they are met with in chains and groups, and by their difference in size and shape can be readily distinguished from the spores of *Leptothrix buccalis.*—*Berliner klin. Woch.*, January 1, 1883.

REMOVAL OF GOITRE.—In the *Deutsche Medizin. Zeitung*, No. 42, an abstract of a case of extirpation of a goitre, performed by Von Riedel, is given, which is unusual in the fact that symptoms supposed to be due to some affection of the vagus occurred soon after the operation. Aphonia, with rapid pulse and dyspnœa, set in within two hours after the operation.

Tracheotomy failed to relieve the dyspnœa. Four days later, pneumonia was detected, and the patient succumbed. At the autopsy the recurrent nerves were found to be embedded in blood-clot; there was also commencing suppurative inflammation of the mediastinum, and lobular pneumonia. Von Riedel puts the vagus symptoms down to the use of a two per cent. solution of carbolic acid with which the wound was washed out. He has seen one other similar case. The facts of the case are interesting, but we think the explanation not free from objections.—*Medical Times and Gazette*, December 23, 1883.

FATTY HYPERTROPHIC CIRRHOSIS WITH ICTERUS.—DR. MERKLEN reports two cases of the above nature which occurred under the service of Prof. Vulpian. From an analysis of their symptoms and the lesions detected post mortem, he draws the following conclusions:

1. The icterus in cases of fatty hypertrophic cirrhosis is the consequence of an acute or sub-acute diffuse intra-lobular hepatitis, which, by the abundant formation of embryonal cells which it causes, arrests the flow of bile in the lobule.

2. The intensity of the icterus is dependent upon the integrity of the hepatic cells, and is less marked when their fatty degeneration is complete.—*Rev. de Méd.*, December 10, 1882.

TREATMENT OF HEMORRHOIDS.—DR. GAVOY has employed the following plan of treatment in rebellious cases of hemorrhoids: it consists in freezing the hemorrhoidal vessels, and so causing an isolated arrest of the circulation. To accomplish this the base of the tumor is surrounded by a thread so as to arrest the circulation; the surface of the tumor is then touched with a piece of ice which is held there for some time; by this treatment the tumor becomes greatly reduced in size. It is not necessary to anæsthetize the patient; the treatment is also efficacious in cases of erectile tumors.—*Journ. de Méd. de Paris*, Dec. 30, 1882.

NEW OPERATION FOR RUPTURED PERINEUM.—At the meeting of the Obstetrical Society of London, held December 6, 1882, a paper on this subject was read by DR. WYNN WILLIAMS. In this operation the sides of the rent were first denuded in the usual way; then a flap of elastic tissue about two-thirds of an inch in width, about two lines in thickness, and long enough when on the stretch to reach as high as the denuded surface on the labia, was dissected up from the floor of the vagina. Sutures were then passed through the denuded surfaces in such a manner as to keep the edges as well as the flat surfaces of this flap in contact with the raw surface. This being done, the sutures were secured in the usual way. When the rupture involved the sphincter ani, the flap was made, and the sutures passed through it in the same way as in the simpler case, but the rent in the wall of the rectum was sewn up with sutures made to terminate within the bowel, and the deep sutures secured before those bringing the flap into position were tied.—*Lancet*, December 30, 1882.

POISONING BY PYROGALLIC ACID.—DR. ERNEST BESNIER reports four cases in which friction with an ointment of pyrogallic acid in cases of psoriasis produced marked symptoms of poisoning. The most severe symptoms were produced suddenly in all cases: hæmoglobinuria and hæmaturia, violent diarrhœa, and pulmonary œdema, accompanied by great collapse; death resulted in two cases. Dr. Besnier believes that the most satisfactory treatment of such conditions is to administer hypodermic injections of ether, inspiration of oxygen, and the free administration of alcohol in small and repeated doses, combined with revulsives, such as cold wraps applied to the skin.—*Ann. de Dermatol. et de Syphilog.*, December 25, 1882.

NEW OPERATION FOR SPINA BIFIDA.—At the meeting of the Leeds and West-Riding Medico-Chirurgical Society held December 1st, MR. A. W. MAYO-ROBSON showed a child, six weeks old, upon whom, when six days old, he had performed a new operation for spina bifida. The redundant parts removed by the operation were also shown. After the removal of these parts, and after stitching up the arachnoid over the spinal canal, periosteum from a rabbit was inserted between the meninges and the skin so as to cover the gap in the bones. The wound had perfectly healed; the skin over the lumbar region was quite level; there seemed to be no tenderness on pressure; the child looked strong and healthy. The sac, examined by Mr. F. H. Mayo, was found to be of the size and shape of half a swan's egg; the wall consisting of true skin and subcutaneous tissue lined by serous membrane. At one point the sac was very thin and transparent, appearing to consist only of the serous membrane covered by a thin layer of epidermis, when fresh minute bloodvessels could be seen to ramify over it. Mr. Robson drew attention to the following points: 1, the operation was performed with full antiseptic precautions, eucalyptous air being used instead of carbolic spray; 2, the meninges were closed by uniting the serous surfaces, as in peritoneal surgery; 3, the transplantation of living periosteum and its continued vitality; it had not yet, however, formed new bone; but already the covering of the canal had a greater than mere skin-firmness; 4, the entire absence of bad symptoms in the child, operated upon at so early an age, was noticed.—*British Medical Journal*, December 30, 1882.

PULSATION OF THE SPLEEN IN AORTIC INCOMPETENCE.—It would appear that this sign of aortic incompetence has not been previously described. Attention has now been drawn to it by Dr. Gerhardt, in the *Zeits. für klin. Med.*, IV., S. 449, without any attempt being made to magnify the importance of the phenomenon. We are familiar with pulsation in the smallest vessels of many of the visible parts of the body in aortic incompetence, including the bed of the nails; and Quincke has shown how the two factors necessary for its production are, relaxation of the vascular walls, and sudden great variation in the blood-pressure, such as occurs in aortic regurgitation. In Gerhardt's three cases the spleen was large and the patients in high fever. The splenic tumor swelled during cardiac systole, expanding gradually, and diminished in size again during diastole. A dull double sound was audible over the tumor, apparently distinct from the cardiac murmurs which could be made out at the upper part of the tumor. To the finger the pulsation had not the characters of an aneurism, but was of the nature of a soft swelling, very much as in pulsating jugulars. The sign appears to be not entirely without some prognostic value, inasmuch as it indicates a sound condition of the left ventricular walls, and compensation, as far as possible, of the valvular inadequacy.—*Medical Times and Gazette*, December 23, 1882.

ARTERIO-VENOUS ANEURISM.—At the meeting of the Société de Chirurgie, held Dec. 6, 1882, M. POLAILLON read a report of a case of an arterio-venous aneurism which became purely arterial by the obliteration of the vein which communicated with the artery. The disease occurred in a man who, when 11 years old, had

accidentally cut himself in the bend of the arm with a pen-knife. An aneurismal tumor of the size of a small nut resulted, and remained without change for forty-two years, when it suddenly increased in size, and caused intense œdema of the arm and forearm, and rupture appeared imminent; the radial pulse could not be felt. The arm was amputated and antiseptic dressings applied. The operation resulted favorably. The examination of the tumor, after turning out the fibrinous clots, showed that it had been an arterio-venous aneurism, but that the humeral vein had become obliterated up to the shoulder, while the humeral artery was atheromatous; the obliteration of the vein was evidently due to phlebitis and thrombosis.—*L'Union Médicale*, December 12, 1882.

Purulent Peritonitis; Laparotomy; Cure.—Anton Schmidt, of Moscow, reports a case of purulent peritonitis occurring in a man, aged 21 years, during convalescence from an attack of relapsing fever. The abdominal cavity was opened by an incision extending from the navel to the pubis, and about five pounds of pus removed. Careful drainage was established, but no injections were employed; a Lister dressing was used. Cure occurred without any complications other than occasional attacks of colic.—*Centralb. f. Chirurg.*, November 25, 1882.

Localization of Articulate Speech.—At the meeting of the French Academy of Medicine, held Dec. 12, 1882, Dr. Bilot presented a memoir on the seat and direction of the capsular radiations whose function is concerned in the transmission of speech. The author believes that, according to his researches, the opinion of Bouillaud, who accorded no more importance in this connection to one frontal lobe than to the other, is more nearly correct than that of Dax and Broca, according to whom the left side alone is functionally concerned with articulated language. If the frontal lobe is not, strictly speaking, the governing organ of speech, it nevertheless contains the agents charged with its transmission. The memoir was referred to a commission, composed of MM Vulpian and Mathias Duval.—*Gazette Hebdomadaire*, Dec. 15, 1882.

Ergot in Diabetes Insipidus.—Dr. Alfred Carter, in the *Birmingham Medical Review* for December (No. 52), gives a brief account of a trial of ergot of rye in diabetes insipidus. The patient was a little girl aged six, who had suffered from her complaint for about twelve months, probably, before she came under observation. The treatment lasted over a period of three months, including a fortnight in the early part during which the drug was suspended. The liquid extract was the preparation used, at first in doses of fifteen minims taken three times daily, afterward gradually raised until no less than nine drachms a day were being administered. He arrives at the opinion that ergot had no notable effect in diminishing the flow of urine for the following reasons: 1. The flow increased for the first three weeks, though ergot was taken. 2. Ergot was resumed after its withdrawal for a fortnight; yet the average flow during the four following days was sixteen ounces in excess of the daily average during the period of suspension. 3. Though the daily flow during the last two months was materially less on the whole than before, yet toward the end of this period it increased some sixteen ounces beyond the average of the earlier part, though at the same time the dose of ergot was systematically increased. 4. On the final suspension of the ergot the daily average diminished at first, and did not afterwards exceed the average flow during the time that no less than nine drachms of the extract were being taken daily. 5. Such improvement as did occur appeared to be more closely related to the improvement of general nutrition than to anything else. We think it is evident, then, that ergot may be added to the somewhat long list of drugs which exert no beneficial influence on this formidable malady.—*Med. Times and Gaz.*, Dec. 23, 1882.

New Remedy for Syphilis.—Prof. Liebreich brought forward, at the last meeting but one of the Berlin Medical Society, a new drug for the treatment of syphilis by the subcutaneous method. This drug rejoices in the name of hydrargyrum formidatum, and is, therefore, merely a different form of the old cure for syphilis. The mode of its preparation was not stated; chemically, it belongs to the amide group, in whose structure the monovalent amidogen (NH_2) plays an important part. Liebreich was led to think of this new preparation from the notion that the ordinary amides of the body, of which urea may be regarded as the principal one, pass out of the organism in an undecomposed state; when, however, an amide is in combination with a metal, decomposition readily occurs, and the metal is reduced and deposited. Liebreich repeated his experiments before the Society, and showed that these conjectures were quite true for the metal mercury. It is supposed, therefore, that the formamide of mercury, after the hypodermic injection, undergoes disintegration; and so the mercury is set free, and is able to exert its well-known power over the lesions of syphilis. The preparation is easily soluble in water, is of neutral reaction, does not coagulate albumen, is not precipitated by caustic soda, and the presence of mercury can be demonstrated by means of sulphide of potassium. The drug, when injected under the skin, produces its effects very surely and rapidly. This is not regarded as a disadvantage, for the medicine is said to be easily borne, and has never produced salivation in Liebreich's hands. There is very little pain attendant on the injection, which has never excited any inflammation. From a half to a whole of a Pravaz syringeful (a one per cent. watery solution) may be injected twice or thrice daily. Liebreich looks on the preparation as the best we yet have for subcutaneous injection.—*Med. Times and Gaz.*, January 6, 1883.

Symmetrical Gangrene of the Extremities.—At the Pathological Society of London, on December 5th, the body of a child, which presented a most remarkable example of this rare condition, was shown by Dr. Southey. The body was that of a well-nourished girl, aged two years and a half. A few months ago, she had a "feverish attack," which was accompanied by some purpuric spots on the limbs. On November 13th, another slight feverish attack occurred, and lasted three days. The child remained in good health up to the afternoon of December 1st; she then complained of headache; on the following morning, she appeared quite well. In the afternoon, she complained to her father that she had "hurt her legs." He rubbed the backs of her calves, but this increased the pain; and he noticed that the skin in that situation was livid; soon after, she vomited, complained of headache, and was "feverish." At 6 P.M. on that day (December 2d), she was worse, the patches on the calves were blacker, and were extending up and down the calves; the parents also noticed, at this time, that the backs of the arms were becoming affected in a similar way. At 6 A.M. on the following morning, it was noticed that the buttocks had become livid. At noon on December 3d, she was admitted into St. Bartholomew's Hospital in a moribund condition; the pulse at the wrist was feeble, somewhat wiry, but could be counted. The tibial pulse could not be felt. The patches of lividity felt hard and tough; the lungs and heart ap-

peared to be quite healthy; liquid nourishment, brandy and milk, were taken, but soon vomited as a rule; two doses of nitro-glycerine were also given, but immediately vomited. At 7 P.M., a convulsion occurred; up to this time, intelligence had been preserved; but, after this, convulsions became very frequent, and she died at 11.45 P.M., on December 3d; the whole duration of the case was thus not much over thirty-two hours. The necropsy had been made by Dr. Norman Moore, but no coarse lesion could be found in the viscera. He had examined the femoral and other arteries of the left lower limb, but had found no embolus. The parts affected were the legs, in almost their whole extent, the buttocks and the neighboring part of the back, the backs of the arms, and the cheeks; the lesions were remarkably symmetrical. A theory to account for these cases, of which Dr. Southey had seen three or four, but none so well marked as this, had been put forward by M. Reynaud, who supposed that there was a spasm of the arteries, with subsequent migration of blood-corpuscles, and transudation into the skin.—*Brit. Med. Journ.*, December 9, 1882.

EXTIRPATION OF KIDNEY.—At the meeting of the Sheffield Medico Chirurgical Society, held December 7, 1882, DR. KEELING showed a large tumor of the right kidney which he had removed, at the Jessop Hospital, by a front abdominal incision from an unmarried woman, aged 23, on August 10, 1882. The tumor was thought to be ovarian in the first instance, its real nature not being ascertained until the peritoneal cavity had been opened. The stump of the tumor, consisting of the pelvis of the kidney and the renal vessels, was secured by catgut ligatures, and a long drainage-tube was placed in the track of the wound. The hemorrhage in the latter part of the operation was severe, and the patient almost pulseless when carried to bed. Convalescence was retarded by profuse suppuration and diarrhœa. The wound was finally healed on the thirty-eighth day; the patient had now (four months after the operation) completely recovered. The tumor was cystic in its character, with strong fibrous walls, continuous, apparently, with the capsule of the kidney. It was developed on the concave aspect of the gland, and the kidney itself, otherwise but little altered in appearance, was flattened out on the back of the tumor. It had been growing for more than three years, but had not given rise to any kidney symptoms.—*British Medical Journal*, December 30, 1882.

IPECACUANHA AS AN OXYTOCIC.—DR. PITKIN confirms the assertion that ipecacuanha administered during tedious labor will augment the energy of the uterine contractions, and reports a case in support of his statement.—*Journ. de Méd. de Paris*, Dec. 2, 1882.

SOME CURIOUS LAPAROTOMIES.—ROSENBACH (*Gaz. Méd. de Strasbourg*, No. 11, 1882) reports the following cases:

1. Extirpation of a cancer of the rectum extending high into the pelvis; detached by abdominal incision, and removed through the anus. The abdomen was opened directly above Poupart's ligament, the sigmoid flexure drawn out, and divided between two ligatures; the upper end of the divided gut was then sutured in the abdominal wound, to form an artificial anus, and the lower end was disinfected and returned, after division of the mesentery, to the abdominal cavity. The abdominal wound was then closed, and the rectum extirpated through the anus. Drainage was carried on through the perineal wound, which was not closed, but stuffed with iodoform gauze. Death occurred from collapse on the second day.

2. Operation for a distended gall-bladder containing a large number of calculi. The tumor occurred in a girl aged seven years; had existed for two years; was the size of the fist, and was situated in the right half of the abdomen; distinct fluctuation could be detected. The abdomen was opened, and the gall-bladder stitched to the edges of the abdominal wound. Ten days afterward the gall-bladder was opened, and a large quantity of clear, mucous fluid removed, and about forty calculi. Cure occurred without any febrile reaction.

3. Extraction of biliary calculi through an abdominal incision. Cure resulted in spite of the fact that several calculi were lost in the peritoneal cavity.

4. Retro-visceral dermoid cyst. Laparotomy to the left of the umbilicus. As the cyst could not be removed, the abdominal wound was closed, and the cyst sutured to it and then opened. Cure took place without febrile reaction.

5. Laparotomy for congenital retro-peritoneal tumor; neuroma of the solar ganglion. (Result not stated.)

6. Laparotomy for intestinal obstruction from compression by an abscess of the pancreas. (Result not stated.)—*Journ. de Méd. de Paris*, Jan. 6, 1883.

LITHOLAPAXY IN INDIA.—DR. P. J. FREYER states in the *Indian Medical Gazette* for December, 1882, that he has employed this operation in ten cases, and he is so thoroughly satisfied with its results in every respect that he has now decided on practically abandoning lithotomy in the adult in favor of the new operation, except in cases of large and hard calculi, and when the case is complicated by stricture. In all cases he introduces a morphia suppository immediately after the operation, and gives ten grains of quinine internally as soon as the patient recovers consciousness. He thinks this plan aids in warding off urethral fever. He believes that litholapaxy will become very popular in India, where the natives are averse to any mode of treatment that involves a series of several distinct surgical operations.

GENERAL PROGRESSIVE MUSCULAR ATROPHY WITH PARALYTIC LUMBAR LORDOSIS.—DR. LUDWIG LANGER reports a remarkable case of progressive muscular atrophy leading to paralytic lumbar lordosis, which is especially interesting from the extreme distortion of the skeleton produced, leading to the supposition, at first sight, that the case must be one of some disease of the bones. It is further clinically interesting from the high degree of development of the characteristic symptoms, and, anatomically, it brought into prominence the action of numerous groups of muscles which ordinarily are not accessible to study.—*Deutsches Arch. f. klin. Med.*, December 18, 1882.

DIAGNOSIS OF TUBERCULAR ULCERATION OF THE LARYNX.—At a recent meeting of the Berlin Medical Society, DR. FRANKEL made an interesting communication on this subject. He believes that in a large number of cases the lenticular tubercular ulcer is quite characteristic. The tubercle is found completely beneath the epithelium and sets up an ulceration, which, in general, tends to spread to the surface; the borders are not sharp, but they can be always recognized by their sloping character from new filtration with recent granulations; the bottom of the ulcer is lardaceous. The ulcer is surrounded by an inflammatory zone, in which deposits of miliary tubercle can also be recognized.

In many cases, however, the ulcer does not have sufficiently distinct characteristics to permit of a diagnosis without the accessory information drawn from auscultation and percussion.—*Rev. Mens. de Laryn. d'Otol. et de Rhinol.*, January, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.

SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, FEBRUARY 3, 1883.

STATE BOARDS OF HEALTH.

IT seems strange that any argument should be required at the present time in favor of the establishment of State Boards of Health; yet such would appear to be the case, if we may judge from the hesitancy with which legislators approach the subject, and their repeated failures to adopt salutary laws, even when endorsed and urged by those best qualified to judge of their character and importance. As an example of culpable indifference and neglect, in staving off from year to year a measure which has elsewhere been demonstrated to be of unquestionable advantage to the health and well-being of the people, the State of Pennsylvania assumes an unenviable prominence.

Annually, for years, the Legislature of this State has had before it a bill creating a State Board of Health, but it has always failed to enact it into a law. At the present time such a bill is again pending, the passage of which, in its main features, is earnestly desired by sanitarians and philanthropists, not only in this Commonwealth, but in the adjoining States, many of which have already been provided with central boards of health, and have a common interest in all measures tending to prevent the spread of disease.

Without a department of public health a State government is deficient in its organization. Agriculture, education, finance, law, fish culture, and the like, are all objects of which the State properly takes cognizance; but what sufficient reason is there for ignoring the equally important obligation to care for and protect the health of her citizens?

The establishment of a State Board of Health is necessary for the collection and preservation of vital statistics. Apart from their essential value as records for future reference in studying some of the great problems of the human family, they will be of immediate and indispensable importance as a guide in searching for the causes which undermine the health and jeopardize the prosperity of the people. One of the most important functions of such a board is that of sanitary investigation and research upon questions affecting the health and life of citizens of the Commonwealth. No better proof of the advantages resulting from the performance of these duties need be presented, than that furnished by the instructive reports of the boards of health of the States of Massachusetts and Michigan.

It should be the duty of the State Board to foster and encourage the study of the preventable causes of disease, and the application of the remedies; to discover the needs of the people with respect to sanitary laws, and to suggest, explain, and recommend the appropriate legislation; to represent and guard the interest of the whole State in national and inter-state sanitary legislation and conferences; and to act as a central bureau for the collection, record, preservation, and dissemination of valuable information on all subjects pertaining to the health and life of the people.

As a medium of communication and of concerted action between local boards of health, and of aiding such boards in the suppression of nuisances when the cause is beyond their jurisdiction, as, for example, in case of defilement of streams and water supplies, such an organization will prove to be of the utmost advantage.

We trust that the members of the Legislature of Pennsylvania will recognize the truth of the old Latin motto, "*salus populi suprema est lex*," and that they will no longer allow the State to occupy the unenviable position of being one of the nine States in the Union which remain without a State Board of Health to investigate, supervise, and advise in the interests of the life and health of the citizens of the Commonwealth.

ANASARCA ACCOMPANYING TYPHOID FEVER.

ANASARCA accompanying typhoid fever appears to be a rare condition in the hospitals of Paris, for M. Leudet has not met a single case in that city in a service of six years, while, curiously enough, he observed eight in the Hôtel Dieu of Rouen, in a short space of time; and Griesinger noted it in one-fourth of the cases of a typhus (typhoid?) epidemic in Germany in 1857. It was also noted by the earlier English physicians, by Magnus Huss in an epidemic in Sweden in 1855, and by Virchow in an epidemic in Upper Silesia in 1849. The occur-

rence in the hospital service of M. Millard, of a case of typhoid fever, in which, after a profuse intestinal hemorrhage on the seventeenth day, there supervened, suddenly, general anasarca without albuminuria, has led M. Ch. Eloy, in a recent number of *L'Union Médicale*, to carefully study the entire subject.

Four classes of cases of dropsy complicating typhoid fever have been observed:

1st. Local and partial œdema, resulting from thrombosis. Such are the cases of thrombosis of the internal saphenous or other veins of the lower extremity, resulting in *phlegmasia alba dolens*, or milk leg, which are by no means confined to typhoid fever, but may occur in any cachectic state.

2d. Anasarca with nephritis, of which Traube reported a remarkable case, in which the œdema was confined to the hands and feet, accompanied by suppuration of the kidney, and believed to have been due to typhoid fever. Such an origin was denied by Rayer, but Griesinger, Frerichs, Rilliet and Barthez, and others still, have observed remarkable alteration of the kidney in this disease. We have ourselves met an instance of this complication—nephritis—which gravely threatened an unfavorable termination of the case, but the patient ultimately recovered.

3d. Anasarca and serous dropsy *with* albuminuria, noted by Griesinger, Harley, and others. In the experience of the former they occurred in the third week, and with the latter on the thirty-fifth day after the beginning of convalescence. In the last case, febrile phenomena and desquamation accompanied the invasion of the anasarca; and in some cases were noted an abundance of sudamina, and sometimes a true miliary eruption. The instance occurring as late as the thirty-fifth day after convalescence began, ushered by fever and desquamation, we should be inclined to consider independent of the typhoid attack, from which it was so far separated. Further we can see no reason for separating the second and third categories. Both must be the result of a renal complication, and seem to differ only in the seat of the dropsy.

4th. Anasarca and serous dropsy *without* albuminuria, occurring in the third week, coincidently with defervescence—the case related by M. Eloy being of this class, which is also the most common, since out of eight cases of the dropsy, albuminuria was absent in six. It is often preceded by copious perspiration or diarrhœa; sometimes by a profuse enterorrhagia, as in the case reported; at others by a pulmonary accident, as bronchitis or pleuro-pneumonia, that is to say, some debilitating cause; and, in general, the subject is a feeble one, and the type of the fever adynamic. Usually the approach is sudden, and for the most part without fever. The urine is commonly increased in quantity, but otherwise normal. The anasarca is not confined to the connective tissue, but may, though rarely, invade the pleura or peritoneum. Its effect upon prognosis is not, as a rule, more serious than to retard convalescence.

As to the pathogenesis of these conditions, neither cold nor geographical peculiarities are sufficient to account for them, and it would seem necessary to admit a morbid condition of all the tissues of the organism, and a dyscrasic state of the blood, provoked in some one of the ways alluded to, or by unfavorable surroundings, as those of famine, poverty, and confinement in prisons, etc. That conditions of the blood have much to do with them is proved by the fact that anasarcas have succeeded upon repeated bleeding in the course of typhoid fever. It is needless to say that a restorative and tonic treatment is indicated.

GAMBETTA—HIS MODE OF DYING.

The lesions disclosed at the autopsy of Gambetta serve to illustrate some interesting and important pathological questions. The perityphlitis, colitis, and the localized peritonitis, whilst the immediate cause of death, were accidents only, arising in the course of a constitutional state. His habits of life were sedentary, and he was addicted to the pleasures of the table. A member of the *bourgeoise* class, whose ancestors were compelled, by the stress of circumstances, to adopt a frugal life, he inherited their constitutional peculiarities. The changed conditions of life as he rose into political importance, and the indulgences which he permitted himself, induced obesity and a depraved condition of his fluids and solids. One of the results of these causes was the development of glycosuria—of that form of the malady associated with a vigorous state of the nutritive functions. Such subjects grow very fat, eat enormously, and pursue sedentary occupations. The condition of glycosuria is not constant, it is rather intermittent, and diet and exercise have a very pronounced effect in causing the disappearance of the sugar. Such subjects, it is now known, may continue for many years to present this congeries of symptoms. Whilst they may not experience very pronounced symptoms from this cause, and may continue for a long time fair, fat, and flabby, they are peculiarly liable to intercurrent diseases of a formidable kind—to serous and parenchymatous inflammations. Such was Gambetta's fate. Confined indoors by a wound, and doubtless poisoned from this source, he experienced an intercurrent inflammation. His system was poorly prepared to resist the inroads of such a malady. His tissues were flabby, watery, fatty, and his vital resources, therefore, at the minimum.

Such a case is a whole series of moral homilies. To the physician the moral is—inculcate the art of right-living, for the secret of prevention consists in the adaptation of the personal hygiene to the peculiar state of the social conditions. We leave to the moralist the lessons appropriate to such a termination of such a life.

THE NATIONAL ASSOCIATION FOR THE PROTECTION OF THE INSANE.

A SMALL number of eccentrics meet semi-annually to discuss the problems connected with the care of the insane. What purpose, soever, may ostensibly claim their attention, the one subject to occupy them is, the abuses of asylum management. They wish everything changed, but, like iconoclasts in general, they are more apt at breaking up than constructing. They are more especially concerned that admissions to asylums should be more difficult—desiring to avoid the incarceration of sane persons, which they affect to believe is very frequent. During the proceedings of the meeting in which the remarkable paper referred to below, was read, a severe rebuke was administered to the authors of these reckless assertions by a former member of the State Board of Charities, who affirmed that, as a result of many years' observation of asylums in Pennsylvania, he had never known of a single instance of the incarceration of a sane person. Dr. John L. Atlee, of Lancaster, confirmed Mr. Well's vigorous statements, and twenty-five years' service as a trustee of the Harrisburg Asylum surely has given him the right to speak authoritatively.

A very remarkable paper was read by a clerical gentleman who may be fitly characterized as a "reverend idol." He held forth on the duty of the sane to the insane. We learn that he belongs to the group of sensational preachers—moral teachers, who are nothing if not startling; who deal in epigram, in antithesis, in paradox, in climax and anti-climax, in any rhetorical clap-trap which will startle their hearers. His paper was a sensational sermon, read in the deepest of clerical bass, and with a manner compounded of pertness, self-sufficiency, and affected modesty, which he has found effective, doubtless, in his congregation of adorers. Too wise a man was he to perplex his audience with weighty problems. He contented himself with portraying the horrors of asylums, the fatal ease with which the sane are incarcerated, and the barbarities of the medical profession. He exhibited a sublime disregard of facts. He began by asserting that insanity was a disease of modern civilization only, that it divided with the "ubiquitous malaria" the attention of physicians, that asylums were dreadfully mismanaged, and that the sane were easily shut up in these monstrous prisons without possibility of escape, condemned to endure perpetual wrongs. He did not instance a single example of a sane person confined in an asylum, although he was not the less confident of the existence of such cases. The chief actors in these iniquitous proceedings are the doctors. They give the certificates on which the victims are confined, a doctor, as an asylum superintendent, holds the hapless subject a prisoner, and doctors are willing witnesses to support any enormity, if properly paid.

All this, and much more, did the "reverend idol" pour forth with self-satisfied consciousness. When his paper was ended interest in the proceedings ceased for him, and he retired, leaving the audience to digest at their leisure his platitudes, and his sonorous but empty paragraphs. The insane who need protection have little hope when defended by such an advocate. "What went ye out for to see? A reed shaken by the wind?"

CARDIACENTESIS.

THE inquiring spirit of the times is well exhibited in the novelty and boldness which characterize the surgical expedients now carried out, or proposed. To reach eminence quickly, the young surgeon must startle. He must explode, so to speak, under the ancient surgical edifice, a cask of dynamite, to awaken the inmates of this conservative institution to a realization of the tremendous revolution going on about them. When these old fellows talk about Sir Astley Cooper tying the abdominal aorta, they are stunned by the intelligence that Billroth removes the larynx, and substitutes a rubber counterfeit, and takes out as much of the stomach as happens to inconvenience the patient. It has not yet been proposed to remove a damaged heart, and substitute a sound bullock's heart; but this operative procedure, as bold as it may appear, is approximated to by the scheme to tap the heart itself, when the venous system is overloaded.

This new operation of cardiacentesis was recently advocated by a New York surgeon. The proposition is to tap the right auricle, and draw off sufficient blood to relieve an overloaded state of the venous system. The reasons, therefore, are conclusive.

> "Whatever skeptic could enquire for;
> For every WHY he had a wherefore."

The small difficulties in the way of this brilliant operation are of little moment compared with the magnificent *coup de théâtre* of the procedure itself. What matters it if any of the great venous trunks are perforated? It is true, when a needle is inserted the movements of the heart must widen the orifice made. An inhibiting ganglion might be irritated, with the effect to slow the already laboring organ.

A motor ganglion might be perforated, suddenly cutting off the nervous force generated by it.

To urge such objections as these, is to indicate a woful lack of that progressive spirit exhibited by modern surgery. Such objectors are inveterate old fogies, who must be abandoned to their idols, as incapable of a higher order of surgical achievements. There are physicians, also, who object to tapping the right auricle, on the ground that the venous system may be unloaded by opening a vein in the arm. A physician who entertains such an opinion is simply incapable of appreciating the triumphs of surgery, and may be classed with those surgeons who are so hopelessly conservative as to prefer some trivial operation to a grand *coup*, which whilst it may end the career of the hapless patient, starts the surgeon on a course of brilliant operative methods.

THE DANGERS OF SEWER GAS.

THE *New York Times* of January 24th has an article upon the dangers of sewer gas, etc., in which Memphis is cited as an example of increase of disease following the introduction of sewers. This article has been prepared without any regard to the facts of the case, very much after the manner of an anti-vaccination pamphlet. It commences by stating that the Memphis system of sewage was constructed under the superintendence of Major Benyaurd, U. S. Army, when in fact Major Benyaurd had nothing whatever to do with the construction, which was effected in part under the direction of Col. George E. Waring, and part under that of the City Engineer. It goes on to say that the result has been a settled and apparently consequent increase of the ratio of mortality, and that the deaths from dysentery have doubled, and those from diphtheria have more than quadrupled. From this it concludes that "it would really seem as if they are right who contend that no ingenuity of trap, valve, or ventilation, no matter how carefully executed in every detail, can prevent the percolation of noxious gases into a dwelling house that is directly connected with sewage mains. It is an assured fact that since the attention of sanitary engineers has been especially directed to this subject in this City [New York], tracing back the agitation for the last three years, there has been a steady increase in the annual ratio of mortality. There have been no great epidemics to account for this fact, tenement and apartment houses have been steadily improving in sanitary provisions, the streets have been kept cleaner than before, our recent structures have comprised all the requisites of good plumbing and good engineering, and yet, as in Memphis, dysentery and diphtheria have obstinately persisted in strengthening their hold. . . Until the present system of direct connection [of our sleeping-rooms with the sewage mains] was adopted, diphtheria was infrequent, and dysentery a rare disease, and it is fair to infer that their recent prevalence is in some manner due to the later mode of building."

The truth is, that diphtheria has been a rare cause of death in Memphis. The diseases to which the largest number of deaths in Memphis during the last three years have been due, are consumption, pneumonia, diarrhœa, and dysentery, and a group of diseases among infants, more especially the colored, variously reported as debility, marasmus, inanition, etc. The prevalence of bowel diseases in Memphis is no doubt connected with its water supply, which is very impure. In short, so far as the records of deaths in Memphis for the last three years have been published, they do not indicate that the sewers have caused disease, except in one way—viz., that the outlet of the sewerage is so situated with reference to the water-works, that at times some of the sewerage is probably mingled with the water supply.

With regard to the statement that recent structures in New York City "have comprised all the requisites of good plumbing and good engineering," etc., the reports of the inspectors of the Board of Health, and the records of trials of "skin plumbers" published in the columns of *The Sanitary Engineer* tell a very different story.

THE PRICE OF SANITARY CORDONS.

FROM the Report on Quarantine for the year 1882, by Dr. R. M. Swearingen, Health Officer of the State of Texas, we learn that to invest the fever district and confine the infection to its narrow boundaries, a double line of guards were stationed, one along the Arroyo Colorado, a stream encircling Brownsville on the east and north, and about thirty miles distant, and the other reaching along the railway between Corpus Christi and Laredo. "The expenses of these extensive lines were necessarily great. September 30 the Marine-Hospital Service had paid out twenty-six thousand eight hundred and fifty-five dollars, and the expenses all told, up to the date that quarantine was raised, must have aggregated sixty-five or seventy thousand dollars." Dr. Swearingen continues, "The good accomplished, however, can not be estimated by dollars and cents. The fact that the epidemic was confined to one place in Texas, while it desolated ranches and towns for hundreds of miles up the Rio Grande on the Mexican side, is strong evidence that the money was not squandered uselessly."

The result may justify the expenditure, but we must not forget that at the same time Pensacola

was suffering from a similar epidemic, and that the disease was confined to one place in Florida without any expenditure for the payment of guards to confine it. In 1879, when a terrible epidemic raged in Memphis, and lesser outbreaks existed in New Orleans, in the Teche country, and various points elsewhere, the disease was confined to these numerous foci at an aggregate cost considerably less than was incurred at this one locality in Texas.

It is true that the Texan cordon guarded a long line of river, but this was done incidentally. The line did not extend along the Rio Grande, but at such a distance in the interior as would have been necessary had Brownsville alone been under guard. The establishment of a close guard is open to the objection of shutting up the whole population in an infected city, thus precluding the application of one of the most rational measures of protection, that, namely, of prompt depopulation, while a cordon placed advisedly at thirty or more miles distance costs sixty-five or seventy thousand dollars.

REVIEWS.

SYPHILIS. BY V. CORNIL. TRANSLATED, WITH NOTES AND ADDITIONS, BY J. HENRY C. SIMES, M.D., and J. WILLIAM WHITE, M.D. 8vo. pp. 461. Philadelphia: Henry C. Lea's Son & Co.

THE reader of this book will find that, despite the long-continued and careful study bestowed upon syphilis, there are yet many things very far from being settled concerning it. If he has adopted the dualistic theory made familiar to American readers by the work of the lamented Bumstead, he will receive somewhat of a shock when he discovers that, while M. Cornil, in common with many other reliable authorities, is a staunch dualist, his American editors incline to believe in the common origin of chancre and chancroid. It will be impossible for him to resist the conviction that Drs. Simes and White in presenting their view reflect the opinions of a small, but growing number of syphilographers; and while he will probably conclude that the correctness of the position of the unicists is by no means established, it will be impossible for a fair-minded man to resist the conviction that neither theory by itself is adequate to explain all the questions which arise. The result of a careful perusal of this volume must be to leave the mind of the student in a somewhat chaotic condition concerning the nature of syphilis. Indeed, when he observes that M. Cornil is a dualist, and that his editors, to say the least, incline to the opposing theory, the reader may almost despair of himself arriving at a fixed state of mind in the matter. Yet, however disagreeable a state of incertitude may be, it is the attitude becoming the true scientist. It might be thought that the time devoted to the accumulation of observed facts had been sufficiently long, and that we might now begin to generalize with safety; but a survey of this book will at once convince that the end is not yet, and that we must yet be prepared to receive further facts, and that the nature of the syphilitic poison, in common with that of tuberculosis, and many constitutional affections, is still undetermined.

The additions of Drs. Simes and White are very considerable, as well as of great importance. The translation has been very well done, and the translators have made some most judicious alterations in the arrangement of the work. A distinguishing feature of the book is the attention paid to histological details and the visceral lesions of syphilis. We know of no work which is of equal value in either of these respects. It is a book which must be studied by every one who desires to acquaint himself with the views of the day concerning syphilis, a disease which seems to be of ever-increasing importance as a factor in the history and well-being of man.

It is to be hoped that Drs. Simes and White may see fit to prepare an independent work of their own upon the subject, which would seem to be warranted by the number and value of their additions to M. Cornil's lectures, and which would more fully bring their opinions before the profession, unhampered by their attitude of commentators.

THE BUSY PHYSICIAN'S VISITING LIST, CLINICAL AID, AND POCKET LEDGER. Detroit: Geo. S. Davis, Medical Publisher.

THIS new candidate for professional favor, as an aid to the daily life of the doctor, has much merit. It is adapted to any date, and can be used both for the daily record of engagements and for an account book. It has calenders, obstetric and annual, metric tables, and rules for the treatment of emergencies, points in differential diagnosis, a list of new remedies, etc. Although we are generally opposed to pocket-books, which aim to provide the physician with medical knowledge, we must praise the good judgment and skill displayed in the preparation of this work. We can recommend it to our readers, as a most useful pocket-book.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting January 9, 1883.

THE PRESIDENT, T. M. MARKOE, M.D., IN THE CHAIR.

EXCISION OF THE KNEE-JOINT.

DR. C. T. POORE presented three patients upon whom he had performed excision of the knee-joint. All the operations were performed with the circular incision. The antiseptic spray was not used. The wounds were thoroughly washed out with a solution of carbolic acid, one to forty. The bones were sutured together with wire sutures, and drainage-tubes passed through the anterior flap around the joint and out through the popliteal space. To secure immobility, the limb was placed on a posterior splint, and a plaster-of-Paris bandage applied from the toes to the groin, an interval being left at the point of operation.

The first patient was a boy, sixteen years of age, with a rather poor family history. He had pulpy disease of both knee-joints. In the right, the tibia was dislocated backwards and flexed at a right angle with the femur. The right knee-joint was excised in 1879, and the result was firm union of the tibia and femur, with two inches shortening. At the time of dismissal from the hospital, he had quite good flexion of the left knee, and was able to act as an assistant to a surveyor, which compelled him to do considerable walking. Last summer he fell and injured the left knee. This was followed by swelling and pains, and it had left that joint stiff in a straight position. Notwithstanding this he was able to walk very well.

The second patient was a girl, thirteen years of age, who fell and injured the left knee-joint six years ago.

The injury was immediately followed by swelling and pain, and six weeks subsequently an abscess formed, which was opened in Bellevue Hospital. She was subsequently a patient at Roosevelt Hospital, where several large abscesses formed about the joint and the lower portion of the thigh, and were opened. She left there considerably improved, but with the limb flexed at nearly a right angle. She subsequently was admitted to St. Mary's Hospital, where Dr. Poore operated upon her in May, 1882, by removing a V-shaped portion of the lower extremity of the femur. There was considerable shortening after the operation, and there still remained a small external ulceration, but no exposed bone.

The third patient was a boy, who had suffered with abscess from Pott's disease, and also had ostitis of the head of the tibia, which opened into the joint. Excision was performed in the usual way, and there was nothing peculiar concerning the subsequent progress of the case, except that on the following day the temperature arose to 105.5° F., but fell to the normal within a few hours, and afterwards there were no unfavorable symptoms except the occurrence of a small slough upon one side of the joint, for which Dr. Poore was unable to account. In this case there still remained a small sinus, into which a probe could be introduced, but he was unable to detect any rough bone.

Dr. Poore had also operated upon another similar case, and expected that the patient would be present, but for some reason was absent. In all the cases the wounds healed promptly, and all the patients were up on the fortieth day.

FIBRO-SARCOMA OF THE PAROTID.

DR. SANDS presented a patient who illustrated the act that in the case of tumors which are unpromising n character, occasionally the disease does not return after removal, or, at least, for a very long period. This man, now thirty years of age, came under his notice in June, 1870. At that time there was a tumor in the parotid region, which was believed to involve the parotid gland. It was situated upon the right side, occupied the entire parotid region, and formed a rather low but extensive growth, which caused prominence of the ear, was exceedingly firm and entirely immovable. It had then been growing for about five months. The case was regarded as unfavorable on account of the rapidity of the growth of the tumor, and the extent and firmness of its adhesions to the deep parts, as well as to the skin. Dr. Sands decided, however, to attempt to extirpate it. When the flaps of skin had been raised, a small portion of the growth was removed, and was examined with the microscope by Dr. Delafield, who found it to be a fibro-sarcoma. The piece removed contained a large proportion of fibrous tissue, with cell elements of a round shape. The diagnosis was confirmed by the subsequent examination of the tumor after its removal. The tumor extended into the deeper portion of the neck, and was attached to the styloid process, and was so incorporated with the adjacent tissue as to make the operation very unsatisfactory. The under surface of the skin was invaded by the morbid growth, being completely incorporated with the whitish tissue of the tumor. Notwithstanding the difficulty of the operation, the patient made a good recovery. Some sloughing of the cutaneous flaps occurred, but beyond this no accident followed the operation, and the patient left the hospital six weeks afterwards with the wound healed. Before the operation the facial nerve was intact, but immediately afterwards the parts supplied by it were found to be completely paralyzed. The paralysis still remains, although it is hardly noticeable when the features are in repose. Dr. Sands had watched the case with a great deal of interest, and made his last note about one year ago, at which time there was no evidence of recurrence of the disease. About three months ago the patient discovered some swellings upon the right side of the neck, and now there can be felt six or eight flat movable tumors extending along the posterior edge of the sterno mastoid muscle down to the clavicle, the largest being about an inch in breadth and length, and about half an inch in thickness. They are very firm, being in this respect like the original tumor. The skin in the neighborhood of the operation seemed to be sound.

DR. MCBURNEY then read a paper on

TRACHEOTOMY AS A PRELIMINARY TO CERTAIN OPERATIONS.

The operations which are referred to in the title of this paper are operations for the removal of the upper or lower jaws, particularly when these parts are involved in the growth of large tumors; operations for the removal of large or vascular naso-pharyngeal polypi, or of tumors springing from the tonsils or walls of the pharynx, or tongue, or palate; and also operations which involve the extirpation of the entire tongue, or of the larynx and adjacent parts; in fact, all operations in the course of which considerable risk is run of having blood or diseased material pass into the lungs or stomach. The old method, so frequently made use of before the introduction of anæsthetics, and still recommended by some, of placing the patient in the sitting posture with the head upright, or hanging forward, offers certainly very slight advantage. Some of the blood lost will, to be sure, flow out of the mouth, but the tendency of such blood as finds its way backwards to pass down the trachea and œsophagus is greater in this position than in any other. Moreover, the difficulty of retaining a patient who is under the influence of an anæsthetic in this position, and the awkwardness of applying artificial respiration, or of doing tracheotomy if suddenly demanded in the course of the operation, and the greater liability to syncope, form very serious objections to it.

Rose's position, or the hanging head, was an ingenious device, undoubtedly applicable to certain cases. Rose placed the patient with the head and neck projecting beyond the end of the operating table, allowing the head to fall so far backwards that its vertex pointed to the floor. The naso-pharyngeal cavity then becomes a cup placed on a lower level than the orifices of the trachea and œsophagus, and blood collecting in it flows more readily out of the nose, provided the nares do not become plugged with clots, than down the pharynx. From this cup-shaped dependent cavity blood can be sponged and readily removed. This position appears to me to recommend itself in cases where hemorrhage will probably not be great, and where the seat of the operation is the palate or mouth, as in cases of cleft palate, or where portions only of the jaws are to be removed without external incisions. But in cases where hemorrhage is very great, or the disease to be removed involves the naso-pharyngeal cavity itself, the Rose position favors the accumulation of blood at the very place where it is most objectionable. Moreover, patients are not infrequently met with who behave very badly when thus placed while under the influence of an anæsthetic, the tension of the larynx and trachea apparently producing a spasm of the glottis which becomes dangerous if not relieved.

Both the upright and hanging head positions are exceedingly awkward in the administration of the anæsthetic, it being necessary to remove the cone as soon as the operation is begun, and to interrupt the opera-

tion at intervals in order to give more anæsthetic. This last is a serious objection, for not only is the operation much prolonged, but blood is frequently lost in large quantities while the mouth and nose are concealed from view. The gravity of extensive and bloody operations about the mouth and adjacent parts has been frequently illustrated in the last few years, not a few such operations having resulted fatally to the patient, either at the time of operation or within a few days thereafter. Moreover, the nature of the disease for which most of these operations are undertaken requires that they should be performed not only with expedition, but with great thoroughness.

I do not know who first suggested a preliminary tracheotomy in the class of cases which I have referred to, but to Trendelenburg is due the credit of giving to the profession an apparatus complete enough to be of very great service in such cases. The original device consisted of a tracheal tube, surrounded in the tracheal portion with a thin rubber bag, which could be sufficiently inflated, by means of a connected bulb, to completely fill the trachea. To the outer end of the tracheal tube an elastic one, several feet in length, was fitted, at the free extremity of which was a reservoir to receive the anæsthetic. The objections to this instrument, as so arranged, are several. In the first place, if the rubber bag was overdistended, which might easily happen, it might burst, or could force its way down so as to close the lower end of the tube. This latter accident occurred to me in one case, and gave considerable trouble. The tracheas of some patients do not bear well the lateral pressure of the bag, violent cough being induced when it is distended. This I have also seen occur. To remedy the first objection, as well as to get rid of the outer bulb, and to obtain greater nicety in fitting the trachea, Dr. Friedrich Lange devised the instrument already shown to this Society. It seems to me to fulfil the indications for either temporarily or permanently tamponing the trachea better than any which I have seen.

Michael, of Hamburg, surrounds the canula with compressed sponge. Over the canula and sponge he places a sack of gold-beater's skin, soaked in a solution of rubber. A little water having been thrown into this sack, the sponge swells and effectually closes the lumen of the trachea. Dr. Foulis, of Glasgow, in extirpating the larynx, tamponed the upper end of the divided trachea with a lead canula which was surrounded with a rubber ring, thus completely closing the air tube and effectually preventing the passage of blood into it.

Dr. Lange recommends in similar cases a leaden canula surrounded with punk, which material is light, and does not allow of the passage of fluids through it. These cases, however, hardly come under the head of preliminary tracheotomy, tamponing of the trachea being necessarily done in the course of the operation. The objects of the preliminary operation are several. Firstly, to prevent the passage of blood down the trachea. Secondly, to facilitate the continuous and safe administration of the anæsthetic. Thirdly, to avoid the possibility of being called upon in the course of the operation to open the windpipe under forced and adverse circumstances. Fourthly, to permit of a continuous, rapid, and *complete* operative procedure, and thus avoid much unnecessary loss of blood. Fifthly, to secure to the patient after the operation an abundant supply of air which is not contaminated by the discharges from the seat of operation.

The passage of blood down the trachea is a danger which always threatens in bloody operations about the upper air passages, and enough fatalities have occurred from this cause to make its prevention worthy of consideration, death having been produced on the operating table, and pneumonia having been produced in other cases from the entrance of blood into the air cells. The unnoticed loss of blood is, in some cases, very great, where the operator depends upon the sponging out the larynx during the operation, blood passing down the trachea, and more especially down the œsophagus, in large quantities. When the trachea is tamponed so as to permit of a continuous administration of the anæsthetic through the canula, this loss of blood can be largely avoided, for continuous pressure can be kept up upon the bleeding points during the course of a long operation, which of course can not be done where the anæsthetic is being repeatedly administered through the mouth and nose. The continuous and safe administration of the anæsthetic has also the great advantage of not only saving time in operating, and, hence, some exhaustion to the patient, but of permitting the operator to deliberately carry out his dissection. In cases of malignant disease, as of the upper jaw, tongue, and pharynx, complete extirpation of the disease is far more likely to be attained where the tracheal tube is used than when it is not; of course, a less rapid recurrence of the disease would then be expected.

The advantages claimed for the preliminary operation can be obtained in a manner somewhat different from, and in my opinion better than, that proposed by Trendelenburg. Instead of the long and heavy tube used by Trendelenburg, one very like an ordinary tracheal tube may be used, into the outer end of which the tube to conduct the anæsthetic from the reservoir can then be fitted. It is not necessary to tampon the trachea itself, as the same effect may be efficiently obtained by packing the lower part of the pharynx with a sufficiently large sponge, to which a string is attached to facilitate its removal. Kocher recommends this plan, but I first saw this method made use of by Dr. George A. Peters, and I have seen it used by others and have used it myself with complete success. It is not perfect, however, for sponge, no matter how tightly packed, will permit of the passage of fluid. I would suggest, as an improvement on the ordinary sponge packing, a sponge covered about half with thin rubber. The rubber side being pushed down and covering the whole lower surface of the sponge, would prevent any drainage through.

There are some questions in regard to the preliminary operation which I am not able to satisfactorily answer to myself. Firstly, is there any advantage gained by doing the tracheotomy some time in advance of the primary operation? Max Schüller, in his monograph on extirpation of the larynx, recommends that the tracheotomy be done some weeks in advance, and claims that by so doing the risks of subsequent pneumonia and bronchitis are lessened. Out of fifteen cases of extirpation of the larynx which Schüller collected, five died of pneumonia, and one suffered from severe bronchitis. But I am not able to satisfy myself that any real advantage would be gained by doing the tracheotomy a long time beforehand, except in cases where the difficulty of breathing through the normal passages caused great impairment of health.

In answer to another question, I think a more positive reply can be made. How long shall the tube be kept in position after the operation?

It should of course be left in all cases where there is reason to fear that the upper orifice of the larynx may become occluded by inflammatory swelling. But another reason for retaining the tube in position is to enable the patient to obtain a supply of pure air during the suppurative stage. Kocher not only keeps the tracheal tube in, but also the sponge tampon in the pharynx, the sponge being soaked in a five per cent.

solution of carbolic acid and removed only to allow the patient to feed. This method also enables the surgeon to treat the wound nearly antiseptically, the nostrils being plugged, the mouth closed though drained into a tube, and frequent washings of the whole cavity being resorted to. I am inclined to think that the comfort and safety of the patient would be increased by following this method in all extensive operations. Michael, Schüller, and others, also claim that by keeping up for some time this permanent closure of the larynx, patients are much less likely to suffer from (Schluck) pneumonia, or foreign-body pneumonia. I have myself made use of a preliminary tracheotomy but three times. In one of these the Trendelenburg apparatus gave me great trouble in consequence of the extreme elasticity of the rubber bag, which folded over the end of the canula when it was distended. In the other two cases for removal of naso-pharyngeal polypi, I made use of a simple canula, and plugged the lower part of the pharynx with sponge. This method gave me great satisfaction.

DR. POST said he had performed preliminary tracheotomy three times; twice upon the same subject after a long interval. In two out of the three times the operation was performed without the introduction of the tube, according to the method of Dr. Martin, of Boston, which he had found very satisfactory. He introduced a large sponge into the fauces, and only a few drops of blood escaped into the trachea. With the open trachea he found it very easy to sponge out whatever blood might enter. He had found great facility in performing tracheotomy as a preliminary operation, and believed that all the advantages which Dr. McBurney had attributed to the operation are derived from it, and that there was no additional risk from performing it.

DR. G. A. PETERS had performed preliminary tracheotomy three times. In one case he had used Trendelenburg's tube. Having seen the difficulties which Dr. McBurney had mentioned concerning the use of this tube, Dr. Peters had had the instrument modified, and supposed that he had gotten rid of the danger, but he then found that another troublesome symptom resulted; namely, a persistent coughing the moment the bag was distended, although he had taken pains to measure the exact amount of air which was necessary to distend the bag up to a certain point. After that, he threw Trendelenburg's tube aside entirely, and had since used only an ordinary tracheal tube, stuffing the fauces with sponge. This method had given him much satisfaction. The anæsthetic could be administered without interruption, and he had had no trouble from blood running into the stomach or trachea. In one of the cases where he used Trendelenburg's tube the patient had a cough which lasted for some time, but he attributed it rather to pressure from the instrument than to entrance of blood into the lungs. He had, however, concluded that the most satisfactory method was to use the ordinary tracheal tube and stuff the fauces with a sponge.

DR. GERSTER had performed preliminary tracheotomy once, and in a case previous to exsection of half of the larynx. In that instance, he used Trendelenburg's instrument, and just after the operation had been commenced the India-rubber bag ruptured, and he was obliged to remove the canula and replace the bag by folds of gauze bound in position by silk. The canula was then reintroduced, and answered the purpose very well. With regard to one object mentioned by Dr. McBurney concerning tracheotomy as a preliminary operation, his own opinion was that preliminary tracheotomy performed a good while before the secondary operation afforded a good many advantages over its performance simultaneously with the operation for the removal of the disease. He recalled several instances where he had been present, and in which considerable time was consumed in performing the preliminary operation; thus in one instance half an hour was occupied, and it could readily be seen that in an anæmic patient the performance of the preliminary operation would necessitate the longer continuance of the anæsthetic and therefore an undesirable exposure to shock. Tracheotomy upon a grown subject was rather an indifferent operation if properly performed, and the necessary care was bestowed upon the after-treatment. The operation was not very serious, and the patient's respiratory tract became accustomed to the tube, and he, therefore, believed it to be advantageous to first dispose of this liability to accident before the operation proper was to be performed.

DR. W. T. BULL had had occasion to perform tracheotomy as a preliminary operation in four cases: three times for extirpation of a portion of the tongue, and once for removal of a recurrent growth from the side of the pharynx. In all instances he had used the ordinary tracheotomy tube. He had not seen any advantages following the use of the tube with the rubber bag. On the contrary he had thought that it interfered with expulsion of mucus from the trachea. He had not left the tube in more than forty-eight hours. He regarded the suggestion made by Dr. McBurney with reference to permanent tamponing the trachea after the operation as a very valuable one, and as an important addition in the after-treatment.

DR. BRIDDON remarked that he had been prejudiced against Trendelenburg's tube, and had simply used an ordinary tracheal tube, packing the fauces with sponges. The operations which he had performed, however, had always been laryngotomies. He thought it unnecessary to make the operation for the introduction of the instrument a tedious one. He believed there was no danger from hemorrhage, which always ceased after the introduction of the tube. He had been favorably impressed in the adoption of Nussbaum's method of narcosis in these cases, that is, to precede the anæsthetic by the use of a large hypodermic injection of morphine, perhaps fifteen drops of Magendie's solution. This is to be followed by the use of an anæsthetic, and he had employed chloroform, administering it to the production of moderate narcosis, and then performing tracheotomy. He had been surprised at the small quantity of chloroform required to maintain insensibility. In one operation not more than three and a half drachms were consumed, and the patient was able to assist at the operation, was sufficiently conscious to be able to empty the mouth of blood, etc., and yet he was placed beyond sensitiveness to the knife. He had not seen Trendelenburg's tube used without the occurrence of some disagreeable accident.

DR. WEIR had performed preliminary tracheotomy in one case with advantage; using only the ordinary tracheal tube, packing the fauces with sponges, and maintaining anæsthesia through the mouth of the tube. He was led to adopt this method because of having previously resorted to Rose's method in the removal of a naso-pharyngeal growth. It was found that the stretching of the neck unduly compressed the trachea and interfered with respiration. In the second case of a similar nature the use of tracheotomy permitted more satisfactorily the dependent position of the head. He was loath, however, to adopt preliminary tracheotomy, because he believed the operation in itself was associated with considerable risk. He had been led to this conclusion from studying the cases in which the operation had been performed for the relief of syphilitic disease of the larynx without much dyspnœa, and for rest of that organ. In two such cases pneumonia had occurred. He had also seen several instances of

cut throat where only the trachea had been incised and where the patient's condition was good, and subsequently chest symptoms developed. He would not resort to the preliminary tracheotomy unless the subsequent operation was evidently to be an excessively bloody one, and with risks not to be avoided by position, slight anæsthesia, etc.

DR. SANDS could recall only a single case in which he had used Trendelenburg's tube, and in that instance it worked very well. Pains were taken to prevent the expansion of the rubber bag over the lower orifice of the canula, and the only inconvenience observed was the occurrence of coughing, as already mentioned by Dr. Peters. He thought that if the instrument could be used with success so far as to completely occlude the trachea, it would form a very valuable invention. He had noticed, however, that it frequently failed to accomplish the purpose for which it was designed, as it allowed blood to pass down into the trachea. He had many times excised tumors of the pharynx and tonsils, or had removed the upper jaw without encountering the least danger from the entrance of blood into the air-passages. He thought that if these points received due attention during such operation, little or no danger need arise from this cause. In the first place, the patient should be placed in a chair with his head inclined slightly forward. In the second place, profound anæsthesia should be avoided, as the blood will enter the larynx only when it is rendered quite insensible, as is the case with deep narcosis. In the third place, it was desirable to operate quickly. In two cases of naso-pharyngeal polypus which he had removed years ago, no blood entered the trachea so far as he could discover, and the patient made a good recovery. The principle of tamponing the trachea was important, however, and he would be glad to see it realized in practice. His own experience had not led him to regard tracheotomy as an operation likely to cause pneumonia, yet he was not prepared to deny that such might sometimes be the case.

DR. GERSTER said that the weight of Dr. Sands' remark was largely in the proposition which he made not to carry the anæsthetic too far. He had had occasion to perform several operations upon the upper jaw, and he had always been careful not to place the patient too profoundly under the influence of the anæsthetic; only just sufficiently so that he would not resist violently enough to prevent the finishing of the operation. In all these cases he had not seen any difficulty whatever, because when any blood entered the trachea, the sensitiveness of that tube induced reflex movements which caused an immediate rejection of the blood.

DR. STIMSON remarked that he doubted whether the patient could always be depended upon to give evidence of the presence of blood in the trachea by cough. He had one patient whom he had anæsthetized six times for the removal of a constantly recurring growth in the upper maxilla. The woman took ether badly, and complete anæsthesia was never obtained for more than one or two minutes at a time. In that case he had seen the pharynx so full of blood that air bubbled up through it, and yet the patient never coughed. He was not positive that blood made its entrance into the trachea, but it was in the pharynx in large quantities, and air bubbled up through it. No bad consequences followed.

The PRESIDENT remarked that during the last fifteen or twenty years he had performed quite a large number of these operations, and he believed that by simply bearing in mind the suggestion made by Dr. Sands, no difficulty need be experienced with reference to a serious quantity of blood getting into the trachea. He believed that in a large proportion of cases the most bloody operations could be performed with safety without preliminary tracheotomy.

FRACTURE OF THE CALCANEUM.

DR. STIMSON presented a specimen which illustrated fracture of the posterior portion of the head of the calcaneum. He believed it to be probably the result of muscular action. The patient was a man fifty-three years of age, who was admitted to Bellevue Hospital in November last for a disease of the tibia which required amputation. Eight years ago, while crossing the street, he was knocked down by a wagon and received the injury which the specimen illustrated. At the time the injury was received, the patient said that the skin was not bruised. The fragment was the portion to which the tendo Achillis was attached, at least partially. It was more than an inch in length, and about three-fourths of an inch in breadth. On its outer side the periosteum was complete; on the inner side there was a growth of bone which presented the appearance of having been the result of reparatory process. The fragment had united with the bone at its upper border, but was about half an inch anterior to its original position. The specimen was accompanied by photographs, and a plaster cast which illustrated the deformity.

DR. BULL thought that pure muscular action could not produce this fracture; that it was the result of direct violence.

DR. STIMSON remarked that there were several cases upon record in which the fracture occurred as a result of muscular action.

DR. PETERS referred to a case, and DR. WEIR to three cases, in which fracture occurred as a result of muscular action.

MELANOTIC SARCOMA.

DR. GERSTER presented a specimen of melanotic lympho-sarcoma, which he removed from the neck of a man on the fourth of the present month. Three months ago the patient got heated from running about, and then sat down in front of an open window and was chilled. This was the only fact which he had been able to ascertain concerning the cause of the growth, although he did not attribute much importance to it as an etiological factor. Immediately after this occurred, the man noticed a slight swelling at the corresponding angle of the jaw, which gradually increased in size. There was no sore throat following the chilling, nor nasal catarrh. The tumor continued to grow and he consulted a physician, who proposed to inject into it tincture of iodine. At that time it was about the size of an Italian chestnut. Considerable reaction followed the injection. The tumor did not resume its former size and shape, but continued to grow rapidly, and after three months it attained the size of a small orange. It was situated in the upper cervical triangle below the angle of the jaw. Laterally it was quite freely movable, not so vertically, and the skin over it was attached to the tumor. Dr. Gerster diagnosed lympho-sarcoma of rapid growth, and gave a grave prognosis. Removal was advised; the exsection was not difficult. Immediately after cutting through the skin it was noticed that the mass had a peculiar dark color. On account of its appearance, and from the fact that through a slight puncture made by a hook introduced into its capsule for the purpose of lifting the tumor up, a black material exuded, he did not attempt to remove the tumor from the capsule, but dissected out the capsule and all, keeping well to the outside of the growth. At the lower and inner part of the tumor, where it approached the superior thyroid artery, there was a dense mass of connective tissue of recent inflammatory origin, which had attached the capsule to the bloodvessel, and also enclosed a small bundle of lymphatic vessels.

Immediately upon the oozing of the black muddy material, which presented the appearance of graphite, through the opening made by the hook, he removed the instrument and applied a ligature round the point, carefully cleansed the part, and then proceeded to the dissection without further assistance of this kind. At the upper and outer angle of the jaw, a large number of lymphatic glands were found which had exactly the characteristics of the tumor itself. They looked like a chain of small blue grapes, and burst as soon as touched. They were dissected away also with some connective tissue by which they were surrounded. When the tumor was cut open, it was found to contain a cavity in which there moved freely a black body that was surrounded by the dark fluid material already mentioned. Microscopical examination revealed that the growth consisted almost entirely of round-celled pigmented elements, with a very sparse stroma. The mass which was free in the centre, was doubtless the original swelling or lymphatic gland noticed first by the patient in the neck. The thick melanotic envelope enclosing this glandular body apparently represented the degenerated glandular capsule. The wound was closed by a few silver wire sutures, and healed by first intention. Early recurrence of the disease is to be expected.

FIBRO-MYOMA OF THE SCROTUM.

DR. W. T. BULL presented a specimen accompanied by the following history: H. C. F., forty-eight years of age and married, entered the hospital October 16, 1882. He gave no specific history, there was no history of cancer in the family, there was no history of traumatism. About twenty years ago, the patient first noticed a small, hard lump about the size of a marble in the lower part of the right side of the scrotum. There was neither pain nor tenderness on pressure, nor discomfort of any kind. This mass gradually increased in size until two or three years ago, since which time it had grown much more rapidly. On admission he complained only of the weight and inconvenience. The scrotum formed a tumor as large as a child's head, the enlargement being on the right side. The skin was normal with large veins, the tumor was ovoid in shape, and reached upwards as far as the external abdominal ring, which was dilated, and filled up when standing by a hernial protrusion as large as a goose egg, which could be easily returned. The surface of the tumor was smooth but uneven, and marked by several rounded projections which were semi-fluctuating. The right testicle was on its lower end softer than the left, and apparently somewhat flattened, but movable in the tunica vaginalis. The circumference of the tumor at its upper limit was fifteen inches, at its lower part eighteen inches, and was of firm elastic consistence, and not at all tender. There was no pain either from it or the hernia. The patient had worn no support. There were no enlarged glands. Removal was advised. The parts were washed with a solution of carbolic acid, 1 to 40, after which ether was administered. Dr. Bull was assisted at the operation by Drs. George A. Peters and R. F. Weir. The hernial protrusion was put back and held, the tunics covering the tumor were dissected down to the capsule, and the cord exposed. A strong piano string was placed round the cord two inches from the tumor, and held by the forceps; the cord was then cut across about one inch from the tumor and it appeared normal, but it was evident at once that the lower end of the hernial sac, which was adherent to the surface of the tumor over a space as large as half a dollar, had been cut across with it. The bloodvessels were ligated with catgut, the wound in the peritoneum was united by continuous catgut suture, the irregular portion of redundant scrotum was cut off with the scissors, a drainage-tube was introduced, and the wound was closed with sutures of carbolized silk, sixteen to twenty in number. Iodoform peat-bags and absorbent cotton were used in the dressing. The patient was discharged from the hospital cured, November 13th. The hernial protrusion was diminished in size, and was retained by a truss. The tumor weighed three and a half pounds. It had been examined by Dr. Satterthwaite, who reported that it was a composite growth, consisting chiefly of ordinary fibrous tissue, to a less extent of fatty tissue, and to a still less degree of non-striated muscular tissue. It was situated behind the cord, which was lengthened, but otherwise unaffected, and above the right testicle, which was normal, as was also its tunica vaginalis. The origin of the growth was apparently from subcutaneous connective tissue, its outer layers forming a sac that was infiltrated with lime salts over most of the surface, while where depositions were absent there were small hernial protrusions of tumor substance.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON PRACTICE.

Stated Meeting, January 16, 1883.

DR. EDWARD G. JANEWAY, CHAIRMAN.

DR. JANEWAY said that he had made a post-mortem examination on a man to-day, who had died of

ABSCESS OF THE LIVER,

in which a quart and a half of pus was evacuated, death being due to peritonitis consequent on rupture of the walls of the abscess. Previous to his death, Dr. Janeway asked the patient if he had had any hypochondriacal or melancholiacal attacks. The patient gave an emphatic negative answer. This was only one of a number of cases of abscess of the liver in which no melancholia or hypochondriasis was present. He therefore believed that these conditions existing in connection with abscess of the liver were the exception rather than the rule.

The paper of the evening was read by DR. HENRY D. NOYES, and was entitled

EYE TROUBLES WHICH MAY BE ERRONEOUSLY ATTRIBUTED TO LESIONS OF THE BRAIN AND NERVOUS SYSTEM,

The author said that the connection which exists between diseases of the eye and other parts of the body, especially with the nervous system, had come to be very thoroughly appreciated. Since it had been demonstrated that the ophthalmoscope could give evidence in regard to more distant parts of the body than the eye itself, it had been employed largely by neurologists and by general physicians. What he had to say was not in disparagement of this use. On the contrary, he thought it ought to be used more extensively than it had been in the past. His remarks were more in the shape of a caveat against erroneous deductions.

Among the objective facts which are observed in the eye with the ophthalmoscope were certain ones which were capable of misinterpretation. We look at the retina with reference to its clearness, and the condition of its bloodvessels. As to the optic nerve, it was asserted that its appearance varied greatly within normal limits, both as to its color and definition and texture. It was very infrequent that optic hyperæmia existed in acute brain troubles; it was, however, frequently present in acute troubles at the base of the brain; but in acute meningitis, or acute inflammation of the cerebral tissue, it was very rare to find evidence of its existence in the optic nerve. Changes in the optic nerve,

when due to brain trouble, were, as a rule, the effect of chronic inflammations, or of new growths, or of interstitial changes which required a long time before they made themselves known. If, therefore, there was redness of the optic nerve, it was necessary that other symptoms should be present before this could be taken as evidence of brain disease. Intense hyperæmia of the optic nerve was shown more commonly as the result of strain, or some defect in the eye itself, than as the result of disease of remote tissues.

One change found in the optic nerve which was significant of brain disease was that of swelling. This condition of choked disks might, however, be present where there was no other evidence of active brain trouble, or the probability of latent brain trouble. In such cases the condition of the nerve should be looked upon as an anomalous one, which was occasionally observed.

The appearance of the retina varies, to a considerable degree, in different individuals. It is frequently seen to present a glistening, opaque look, especially along the line of the bloodvessels. This should not be mistaken for perivasculitis. It does not indicate that there is a condition of inflammation.

Moreover, the general illumination of the fundus varies greatly with the size of the pupil and the complexion of the patient. This could be seen by an examination of any of the figures in books illustrating the normal variations. Sometimes there is seen a bright, opaque striated surface, running out from the nerve itself, which might be mistaken for an exudation. The speaker remembered a case where he committed this error, and supposed it to be indicative of inflammation with exudation, whereas it is by no means infrequent, and denotes an imperfect development of nerve fibres; that is to say, it is a congenital condition, which has no influence upon the real function of the eye, or any bearing upon other conditions of health.

Sometimes the optic nerve is very pallid and the retinal vessels small, and there may be a shallow excavation. This condition might be supposed to be indicative of atrophy, whereas it may be only due to the general poverty of the circulation. There were many singular anomalies familiar to ophthalmoscopic investigators which might be alluded to, but, under the circumstances, they were, he thought, apart from the subject of the paper. Dr. Noyes said, however, that he desired to call attention to the fact that an experienced observer may mistake the appearance in the eye for evidence of inflammation, as had occurred in a case under his observation, in which an English ophthalmologist had supposed intracranial mischief of some sort to exist. Dr. Noyes found, after fitting the patient with appropriate glasses, to correct a marked hyperopic astigmatism, that his vision became $\frac{20}{20}$. The other eye was removed, because of a tumor within it, and the mental symptoms disappeared entirely. This was a case where the mental symptoms were undoubtedly due to the refractive error which had not been observed by the physician who had previously examined the patient.

These were some of the objective errors. Putting that subject aside, there were a series of symptoms of subjective character, which were very likely to be mistaken for troubles of the nervous system. These were principally cases of refractive error, such as hypermetropia, astigmatism, and troubles with the extrinsic muscles of either eye. This was not a new subject. Its full discussion was perhaps due more to Dr. Weir Mitchell, of Philadelphia, than to any other gentleman; but the experience which the author of the paper had with these cases, he thought, entitled him to make reference to them. Errors in refraction, as far as the symptoms are concerned, are the same as simple spasm of the accommodation without error of refraction; but the class of cases which Dr. Noyes now signalized were those where patients made very little complaint in regard to the eyes, and in some cases where there was no complaint whatever. The patient has thus impressed the physician with the idea that some other portion of the body was affected. The chief symptom which manifests itself in these cases is that of headache. The headache can be of any possible variety, and of any possible degree. It can be frontal or temporal; it can be confined to the vertex, the occiput, or even to one side of the head, although this latter variety is comparatively rare. This headache may or may not be associated with the use of the eyes. The patient may arise in the morning with a headache, or it may come on after an increase of any mental labor. Connected with the headache will be another symptom, which may be regarded as more significant—namely, nausea. It is not uncommon for nausea and headache to be associated together, nausea being present at intervals, while the headache is exceedingly persistent.

Take a case in which the patient makes no complaint of any trouble with the eyes, but speaks of severe headache, and suppose that you have occasion to examine his eyes to see if any information can be obtained in them to explain the symptom, and suppose that you find in one eye a deep degree of congestion, and in the other eye redness and opacity of the nerve, this condition might lead to the belief that these are cases of chronic meningial trouble. We might suppose that this opinion was reinforced by appearances of exudation and a fringy condition of the edge of the nerve. The same symptoms can exist without there being any refractive error.

To illustrate this point, Dr. Noyes read a letter from a physician, who had sent to him a young lady supposed to be suffering from slight spasm of the internal recti muscles, which contributed towards certain external symptoms. She complained of certain vague symptoms. She experienced a sensation of distress in sitting among persons, and disliked to look into the eyes of other people. She had loss of sleep, inability to sit, and likewise experienced a sense of mental fatigue, all of which symptoms indicated a considerable degree of disturbance of the psychic system, which was presumed to lie beyond the influence of the eyes. Hysterical convulsions had occurred, and four years previous the patient had a transient goitre. Later she fell, striking upon the end of her spine, at which point there was much tenderness upon pressure. There was no trace of uterine or ovarian disease.

Upon critical examination of this patient it was found that a large part of the cerebral disturbance was due to intense spasm of the muscles of accommodation. Under the free and vigorous use of atropia the spasm was much relaxed, but up to the present date had not been wholly overcome. The origin of this spasm was remote, and doubtless could be explained by the injury to the spine which the patient had received.

Dr. Noyes remarked in passing that he had seen not a few cases where serious ocular trouble depended upon concussion of the spine; the latter giving rise to a morbid condition of the extrinsic muscles of the eye. He said that he would take the liberty of reading a second letter in which the particular trouble was due very largely to a disordered condition of the muscular apparatus of the eye. A young woman, 32 years old, was near-sighted, and had divergent strabismus. She subsequently developed other symptoms and the question was, whether these were not due to her strabismus, the latter being supposed to be of congenital origin. She was seen some years ago by an ophthalmic surgeon, who advised no interference. During her teens

she suffered from violent headaches. Three years ago she had an attack of melancholic insanity of a few weeks' duration, together with other symptoms. The last attack resulted from a fall upon her head. The physician made the diagnosis of primary curable dementia. The patient had chloro-anæmia, with a very marked bruit in the carotid and at the base of the heart, and there was probably also present lithæmia. The symptoms indicated the condition of impaired nutrition rather than congestion, insomnia and disturbance of vision. She now complains of buzzing noise in her ears, and has always complained of hallucinations. What is especially important is that she cannot use her eyes without pain. This, the attending physician thought, might be attributed to the strabismus.

Dr. Noyes said that the case was, in his own judgment, one in which the symptoms were to be attributed to the condition of the eye. He therefore determined upon an operation for the divergent strabismus, which resulted satisfactorily, not only in relieving the local pain, but her health, also, improved materially afterwards.

This subject of irritation as the cause of disturbance of the ocular muscles, is one that has been debated considerably, and is one about which there is not a perfect consensus. There is no difference of opinion about the disturbance of the ocular muscles. While, on the one hand, there are assertions which are not in accord with experience, Dr. Noyes was of the opinion that these muscular disturbances exert a far greater influence, not only over the functions of the eye, but also over the functions of the health in general. As an illustration of this, he took pains a few mornings since to study the symptoms of a little girl, fourteen years of age, who had been brought to him by her mother. The mother stated that the child had suffered from headache for three years, and that she had made up her mind to consult a specialist. The question was, whether to go to an oculist or a neurologist. A headache had existed for three years, and had become worse of late. When she looked hard at people they seemed to go away from her. She has a headache several days in a week, and very often wakes with it in the morning. In spite of the headache she often continues to read, as she says, for the purpose of forgetting it. The pain is principally in the occiput. A jar upon the feet, or a slight blow upon the head, is very unpleasant. In her personal appearance she is healthy. She has a slight tenderness over the supraorbital region, upon the right side. She sometimes passes her hand over her eyes, to clear away the mist. On testing this patient with prisms, he found no important muscular error, but when the child was asked to look at a finger held close up to the face, it was noticed that it was difficult for her to keep both eyes upon it; and when it was held very close, one eye would deviate to one side. The diagnosis was extreme debility of the internal recti muscles, which has given rise to the condition of headache.

The symptoms which persons who suffer from this disease have, are headache and nausea, and an inability to look continuously at an object, and pain easily aggravated by the use of the eyes. They cannot ride in the cars, or look out of the cars because it excites headache. This was a brief statement of this class of cases.

Now, how are these cases to be recognized and errors to be avoided? In the first place, errors may be committed in using the ophthalmoscope, owing to insufficient experience with it, the observer not being familiar with what is normal and what is abnormal. But it is more important, perhaps, that the instrument shall not be employed according to one method only, that is to say, by the indirect method, when the mirror is held in one hand and a lens in the other. A much more valuable mode is the direct method, which consists in the use of an instrument supplied with glasses to correct this vision of the patient as well as that of the observer, and showing whether you are dealing with a normal or an abnormal eye in regard to its refraction. With such an instrument you can get a much better idea of the appearance of the eye.

Finally, under suitable circumstances, the resort to atropia is advisable. Now, if one uses atropia in an examination of eyes for suspected brain trouble, precaution is necessary. With the ordinary size of the pupil it is necessary for the observer to have considerable expertness in order to get a correct idea of the condition of the eye. If you are to examine a patient who is liable to become blind from brain disease, and you wish to use atropine, it is proper to assure your patient that no ultimate trouble can result from its use, otherwise disagreeable feelings might be entertained on the part of the patient towards the physician. On the other hand, when the symptoms are of a subjective kind and are due to refractive and muscular errors, atropine may not only help the examination, but may remove the headache. This removal of the headache may be only temporary, permanent relief coming only after suitable optical corrections by means of glasses. The difficult refraction cases are those in which there is a considerable degree of astigmatism. In a considerable proportion of cases astigmatism complicates the refractive error. The degree to which subjective symptoms make their appearance varies greatly according to the temperament of the patient and his general condition. This is especially shown in those instances when the trouble is due to uterine disease. In muscular errors the treatment consists in fitting the patient with suitable prismatic glasses, and sometimes in the use of tenotomy, and in the treatment of remote discoverable lesions which will have an influence upon this trouble. Both refractive and muscular errors may be combined together, and sometimes in such a manner as to make the prescription of glasses exceedingly complicated.

DR. MARY PUTNAM JACOBI remarked that the subject of the paper was one that interested her extremely from a neurological, rather than an ophthalmological, point of view, although she believed it was eminently proper for one interested on the nervous side of these cases to examine into the other side, for it was a neurologist (Dr. Weir Mitchell), and not an occulist, who first called attention to this condition. It was probable that it was intimately associated with the anatomy of the part. In the cases referred to with functional disturbances of the eye, spasm of the internal recti muscles was usually found. She did not know whether or not it was the generally accepted view that this spasm of the internal recti was dependent on the close association of the optic nerve with the corpora quadrigemina. She alluded to the fact that spasm of these muscles had been induced by falling on the end of the spine. Similarly, concussion of the corpora quadrigemina and the cerebellum would serve to explain the curious symptoms of nausea and vertigo which have often been observed in these cases. She supposed that this condition might give rise to a considerable amount of psychical disturbance. Such disturbances may depend upon the constant strain produced by the blurring of the objects the individual was regarding. She thought it was very extraordinary that in insanity, associated with visual hallucinations, we did not more often find disturbances of the eyes. When she and Dr. Seguin were visiting the Hudson River State Hospital for the Insane, the latter examined all of the male patients having visual hallu-

cinations, and found remarkably few refractive errors. She alluded to a case that recently came under her observation. The patient suffered from visual hallucinations, without any other symptoms. This condition had lasted for several years, and was due to no discoverable cause, unless to reflex uterine irritation. In that case the eyes were examined, and not the slightest trouble was found.

DR. BEARD wished to ask Dr. Noyes whether he had watched cases of the character he had described in his paper, for a number of years after treatment had been discontinued, in order to ascertain whether the relief afforded was permanent, not only with respect to the ocular trouble, but also to the general condition. A second point of much interest to him was, how to tell whether this condition of the eye was the result or the cause of the disease. He had found it impossible in any case to answer the question completely. This whole subject, it seemed to him, was to be referred to a general condition. The entire body is a bundle of reflex actions. The same statements that apply to the eyes, are applicable to the stomach, the urethra, the rectum, etc., but he had never seen a case in which permanent relief had been obtained by the use of glasses alone. The result of his observations and experience is that the relief of the local irritation was only a help, and did not serve to effect a cure independent of other treatment.

DR. PUTZEL thought that an important point had been overlooked. Stress had been laid on reflex action in these cases. He thought that there was a continual outflow of force which must cause a constant strain on the nerves, which strain would induce a condition of neurasthenia. In regard to the mode in which reflex irritation acts, that it is confined to the corpora quadrigemina, he was unwilling to admit. It seemed to him probable that it acted more generally than upon one local centre of that sort.

DR. BIRDSALL had used the method recommended by Dr. Noyes, and with a partially successful result. The patient was a boy about twelve years old, suffering from an intense headache. This was aggravated by reading, and particularly by pursuing his studies in school. The patient, when seen, was in somewhat of a maniacal condition, in which there were hallucinations, and which at times seemed to take very nearly the form of an epileptic or hysterical seizure. The mother thought the boy unconscious at times, as he would lie in a stupid state. Usually the headache was followed by a period of excitement, after which he would lie down, sleep for several hours, and wake up relieved. Glasses were ordered. The relief they afforded was very decided, for a time the patient being relieved from headaches. After a few weeks they returned at greater intervals, and he was ordered to leave school. Subsequently, on resuming his studies, the headaches again came on, but the maniacal attacks did not return for a time. In the course of a year, however, they made their reappearance, though they were less violent. After a time the patient was taken out of school altogether and sent to the country. In the course of a few months he recovered his health entirely, and was now apparently a perfectly well boy. Dr. Birdsall was inclined to believe that the trouble, in this instance, was not due to any disease of the eye, but was caused rather by the condition of his general nervous system. He had, moreover, seen similar cases in which similar attacks had been relieved by correction of errors of refraction. He thought the condition referred to ought not to exist if the nervous system was in a healthy state.

DR. JANEWAY suggested that the class of cases alluded to by Dr. Beard was not the same as that alluded to by the author of the paper, and that they were undoubtedly due to error in the development of nervous tissues.

DR. WEBSTER testified to having seen many cases permanently relieved by the correction of error of refraction. Dr. Birdsall's case called to mind the difficulties that were sometimes met in treating these cases. In prescribing glasses it was proper first to order those that would correct *only the manifest* hypermetropia. Such would afford relief for a time, and in some cases proved to be all that were necessary. If symptoms begin to return the eye should be tested again, and another pair of glasses prescribed, which would, in all probability, be found to give permanent relief. If not, by renewing the glassses every six months all the hypermetropia would be finally corrected.

In closing the discussion DR. NOYES testified in most positive terms to having seen many cases permanently relieved by simply prescribing appropriate glasses.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, January 11, 1883.

THE PRESIDENT, JAMES TYSON, M.D., IN THE CHAIR.

DR. E. T. BRUEN presented a

SMALL TUMOR OF THE HEAD OF THE PANCREAS,

about two and a half inches in diameter and closely adherent to the common bile-duct. The growth is of a colloid nature, but its histological character is unsettled by microscopic examination. There were no secondary deposits in any other viscera, as is the rule in colloid growths. The patient was a male, æt. about 65 years, who, for two years prior to death, had intermittent attacks of jaundice, attributed to catarrh of the biliary duct. The case was under observation for two months. At first the symptoms of chills and fever led to treatment for malaria, but as the jaundice gradually deepened, treatment for the supposed catarrhal state of the bile-duct was instituted. The futility of a well-directed and usually successful treatment was the special indication of some more substantial cause. Hepatic trouble or biliary calculi were readily excluded, but there was nothing to fasten suspicion on the pancreas. There was constipation with clay-colored stools. There was febrile movement of hectic type—the so-called hepatic fever, accompanied by irregular chills. Intestinal indigestion was not marked. Indeed, without exception, the negative results of the clinical record are of the most discouraging character. The case is presented because each case of pancreatic disease ought to be recorded, so that many cases viewed collectively may contribute to the clearness of a future distinct picture of pancreatic disease.

DR. FORMAD said that he had notes of the autopsies of five or six cases of cancer of the pancreas, with marked jaundice. It seemed to him that the jaundice was most persistent in primary pancreatic carcinoma from pressure on the bile-duct. He did not think that the tumor just presented was carcinomatous, as there would then probably have been secondary growths in the liver. The growth was probably a cystic colloid.

DR. BRUEN called attention to some forty cases of jaundice due to primary carcinoma of the head of the pancreas, lately reported by another observer, from which it was demonstrable that jaundice was an invariable symptom of primary hard carcinoma of the head of the pancreas, while it was uncommon when the disease was secondary or affected other parts of the organ.

DR. JAMES TYSON then presented a specimen of

DIAPHRAGMATIC HERNIA,

from a German about 27 years of age, who had been ailing since February, 1878, when, stretching himself,

his wife suddenly pretended to tickle him. He quickly threw down his arms, and at that moment felt a sensation of pain on the left side in the neighborhood of the heart. At the same time he felt faint and cold. In five or ten minutes these sensations passed away, but he remained very much frightened. When first seen by Dr. Tyson, in June, 1880, he could not even walk across the floor without becoming completely out of breath, but he said he was not short of breath when the accident first occurred. He had also a peculiar puffing expiration which did not occur, however, with every act of expiration, but once in four or five. There was no cough. Physical examination revealed, on inspection, almost total absence of movement of the chest-wall in the upper half, the respiration being almost purely abdominal. The upper percussion border of the heart corresponded with the junction of the third rib with the sternum, and the right border with the middle of the sternum. The apex beat was in its normal position, but was more diffuse than in a strictly normal state. Pulmonary percussion appeared normal, except below the left scapula, where resonance was less than in the corresponding situation on the right side. Vocal fremitus was impaired over the whole of the left lung. There were no abnormal cardiac murmurs. He was treated at various times with digitalis, bromide of potassium, chloral, tonics, etc., and even a blister was put over his heart, with the view that there was some cardiac, or pericardial affection, although the physical signs were wanting. There was no improvement, although at times the dyspnœa, which was the most distressing symptom, seemed sometimes less. His death occurred December 15, 1882, from obstruction of the bowels. At the autopsy it was ascertained that about 20 inches of the large intestine, with its corresponding mesentery and almost the whole omentum, had ascended through the œsophageal opening of the diaphragm into the left pleural sac, encroaching upon the space occupied by the left lung until the latter was compressed into the apex of the left pleural sac and was reduced to a cylindroid mass, about 15 centimetres in length and half as many in diameter. There was no hernial sac, the opening being that for the œsophagus. The case was, therefore, technically one of hernia diaphragmatica spuria. The heart was displaced to the right, but was otherwise normal; the liver was slightly fatty, but the other viscera were normal. It is not unlikely at the moment referred to in the history, when the patient threw down his arms, that a small portion of the omentum or mesentery slipped through the œsophageal opening, and that subsequently and more or less gradually the vacuum tendency of the pleural sac in each act of respiration caused the remainder of the mass to be drawn in until the entire cavity was occupied. This accounts for the fact that there was no dyspnœa at the beginning, but that it gradually increased as the thoracic space was intruded upon. In vol. 81, 1882, of *Virchow's Archiv*, will be found an exhaustive article on Diaphragmatic Hernia, in which 291 cases are collated. In a somewhat hasty examination of this paper, Dr. Tyson has been unable to discover a single case so long under observation as this—nearly four years. Many cases were discovered at the autopsy and had been unsuspected, others were congenital, and others were traumatic.

DR. BRUEN asked if there had been any hiccough? If so, was there any dysphagia with solid food? Finally, did the physical signs suggest pneumothorax?

DR. ROBERTS made some remarks with reference to the diagnosis and to the possibility of laparotomy in similar cases. He also asked whether the symptoms just preceding death were those of strangulation.

DR. DAVIS referred to thirst as a prominent symptom according to Lawrence.

DR. TYSON replied that Dr. Formad had told him that there was decided hiccough. There was no true tympany, with the absence of the vocal fremitus. Nothing gave rise to any suspicion of its true nature. Thirst was marked. There was no dysphagia.

DR. J. H. MUSSER then presented the specimens from a case of

ULCER OF THE STOMACH IN THE ANTERIOR WALL; ADHESIONS TO THE ABDOMINAL WALL; HEMORRHAGES AND PAIN; DEATH FROM MORPHIA HABIT.

J. J., aged 71 years, millwright. Fourteen years before his death he was attended for hæmatemesis occurring after three days of nausea. Over a pint of blood was vomited, and considerable was discharged by stool the next day. In ten days he returned to work and enjoyed good health for two years, with the exception of occasional attacks of indigestion. Then a recurrence of nausea, followed by a profuse discharge of blood per anum, occurred. He made a full recovery, but pain after eating was now noticed. Two years subsequently he bled very much from a wound of the foot; was much prostrated thereby. This was succeeded by severe pain after eating, with marked epigastric tenderness. The constant use of narcotics alone gave him relief. November, 1873, he was again under treatment for gastric ulcer without any avail, save when he exhibited narcotics. He resorted to the use of morphia, and continued its use during the remainder of his life. Change of diet did not influence the pain, and he partook of a laborer's fare. In 1877 a small tumor to the left of and several inches above the umbilicus, hard, tender, and apparently involving the abdominal wall was discovered. For several years he worked in a country sawmill, using one drachm of morphia a month. Heavy lifting aggravated his pain. In August, 1882, the patient took to his bed. Death took place. The only anatomical alteration noted at the autopsy was the change in the stomach. The organ was enlarged and contracted (hour-glass) towards its fundus. The anterior wall, one-third of the distance from the fundus, and at the point of constriction, was adherent to the abdominal parietes to the left of the median line, three inches above the umbilicus. Opposite to the point of adhesion in the mucous membrane there was a small ulcer two lines deep and six in diameter, with clean-cut edges, a healthy floor, and surrounded by cicatricial tissue for a radius of one inch. Undoubtedly the ulcer would have healed entirely had not the morphia habit cut off the patient. Dr. J. H. Musser thought that it was plausible to suppose that the first hemorrhage, taken with the profuse foot hemorrhage, was due to the patient having been of an hemorrhagic diathesis, and that the second gastric hemorrhage was from the same cause, and was attended by a hemorrhagic infarct, with subsequent development of the ulcer. Especially is this possible, as it was only after the second hemorrhage that pain occurred, and this symptom is never absent, "except in cases which run a rapid course" (Da Costa).

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

DRS. WILLARD PARKER and FRANK H. HAMILTON are doing well. The former has suffered for some months from a disease of the urinary organs connected with advanced life, and his condition has been a troublesome one.

A RECEPTION TO MR. F. SEYMOUR HADEN, OF LONDON, AND TO MEMBERS OF THE NEW YORK ACADEMY OF MEDICINE is to be tendered by the Presi-

dent and Vice-presidents of that Society, upon the evening of February the 10th, and the invitation has been extended to all to "Join in the Loving-cup," that relic of the round-table which suggests free-boasting and convent-robbing and revelry, which are quite inconsistent with the dignity of the gray-haired solons of the medical profession of this city, whose deeds of daring are ordinarily committed with the blunt-hook, or the scarifier.

It is to be regretted, by the bye, that this body will not accept the munificent offer of the Army Medical Museum Library, and exchange some of their duplicate pamphlets and books for an equal number of rare foreign pamphlets.

THE NEW YORK COUNTY SOCIETY'S DELEGATES.—It is strongly hinted that if the medical delegates from the County Society are not supported by the delegates from the other county societies in the matter of the new Code, that next year they will refuse to go to Albany.

BALTIMORE.

(From our Special Correspondent.)

THE PREVALENCE OF SMALLPOX.—So much has recently appeared in the public prints concerning the prevalence of smallpox in this city, that a brief statement of the true history and actual extent of the disease in our midst may not be unacceptable to the readers of THE NEWS. At the outset, it may be well to state that the reports have been very grossly exaggerated, and that in no sense can the disease be considered to be epidemic. Indeed, in no single week has the mortality equalled one-half of the highest weekly death-rate from smallpox recorded in 1872–73, when we last had the scourge, and when we escaped the unenviable notoriety that we have lately acquired with less justice. Smallpox has prevailed in Baltimore at pretty regular intervals of ten years for a period dating from early in the century. The cause of this is probably to be found in the general neglect of vaccination during periods of freedom from the disease, whereby the number of susceptible individuals gradually increases, until a large proportion of the community becomes ready to be infected by the varioloid poison. From the disappearance of smallpox in the spring of 1873, in consequence of the thorough system of vaccination adopted by the Health Department, smallpox found no lodgement in the city until the closing week of 1879, and then for only a brief period. On December 27th a man was discovered at the ticket office of the Baltimore and Ohio Railroad with an eruption that proved to be that of smallpox. He was forthwith sent to the quarantine hospital.

On January 11, 1880, a man who conducted his business in the vicinity of the station, and whom the original patient (Cordes) had engaged in conversation before his detection, sickened with smallpox, was sent to the hospital, where he subsequently died. On January 13th, four children of the proprietor of a saloon in which Cordes had called upon his way to the station, developed smallpox, and on the 15th the wife of the proprietor sickened with the same disease. They were also sent to the hospital. On January 26th, a man who had worked at the saloon at the outbreak, but who had moved to another house, was attacked with smallpox and was removed to the hospital. No further development of the disease was observed in the city. On Christmas day, Cordes, the original patient, who was apparently a tramp, had called at a tavern on the Frederick Road, near the city, and shortly afterwards four persons in the house developed smallpox. These facts were reported in the *Bulletin of the National Board of Health* by Mr. A. R. Carter, the indefatigable Secretary of our own Health Board. They are interesting as showing periods of incubation in the several cases. The active measures adopted probably checked the further progress of the disease. In June, 1881, one case was reported at Locust Point, the southeastern water front, but no new cases seem to have resulted from it. The present visitation dates from November 4, 1881, when a colored child, lately arrived from Allegheny City, developed smallpox. It resided in Franklin Street, in the northwestern section of the city. Some relatives of this child carried the disease to Pine Street, in a more central location, and other inmates of the house on Franklin Street were attacked. The disease spread slowly; scattered cases reaching South Baltimore, where there is a densely crowded colored population, in January and February, 1882. The eastern section of the city was not invaded until July, when near the water front of the eastern portion, a crowded and ignorant population, composed largely of Poles and Bohemians, was attacked. The gradual advance of the disease can be realized by an examination of the mortuary reports for the months of which we have been speaking, and for the succeeding ones until the present.

DEATHS FROM SMALLPOX.—1881, Nov., 5; Dec., 5. 1882, Jan., 2; Feb., 6; March, 10; April, 12; May, 17; June, 13; July, 22; Aug., 24; Sept., 71; Oct., 63; Nov., 94; Dec., 217.

Already in August, 1882, the Commissioner of Health, Dr. Benson, appointed additional vaccine physicians, so that by Jan. 1, 1883, his force of about thirty-five physicians were busily engaged in their work. The sudden increase of mortality during the month of December, however, warned the city authorities that in order to promptly arrest the progress of the disease more active and thorough measures were necessary. The Commissioner of Health, therefore, acting under the advice of the Mayor, increased the vaccine force to over one hundred, and the work of systematically inspecting and vaccinating the whole population was forthwith begun. Already the beneficial effect of this wholesale vaccination is apparent in the diminishing number of new cases and of deaths. Of course, but little perceptible influence could be expected during the first three weeks of the month, but as the result of vaccination begins to become apparent, the outlook becomes most encouraging. Since January 1, 1883, the vaccine physicians have reported 102,800 vaccinations; these, with the public school vaccinations, and the work of the regular vaccine physicians during 1882, will amount to more than 200,000 recent vaccinations by public officers. Probably 100,000 persons have been vaccinated by private practitioners. Within a few weeks the vaccine physicians will have completed their systematic visitations, and we may confidently hope to have the smallpox entirely under control before the first of March. The returns for the weeks of the present month will exhibit the progress of the disease during the earlier portion, and the influence of vaccination, as shown in the last week's returns.

Mortality for smallpox for the week ending January 6, 79; January 13, 83; January 20, 92; January 27, 75. There were reported for the week ending January 12 (new cases), 264; January 20 (new cases), 296; January 27 (new cases), 256. There remain (January 27) 469 cases of smallpox in the city, in 398 premises, as shown by the records of the Commissioner of Health.

It will thus be seen that, even at the worst, our condition has been greatly exaggerated by report, and that we have suffered less from smallpox than other cities, about which no excitement has been raised. It is too early yet to expect the full effects of general vaccination to be manifested, but there can be no doubt that we are rapidly becoming a well-vaccinated community,

and that a few weeks will witness the complete disappearance of the scourge from our midst. Indeed, we already see the beginning of the end. Devices to escape detection are numerous and ingenious. Not many cases, however, remain concealed, since the returns of physicians, the inquiries of the public, the jealous watchfulness of neighbors, investigations of sanitary inspectors, and the fear of the law bring most cases to the knowledge of the authorities.

WASHINGTON.

(From our Special Correspondent.)

NATIONAL BOARD OF HEALTH IN CONGRESS.—On January 26th, Mr. Harris, from the committee to investigate and report the best means of preventing the introduction and spread of epidemic diseases, reported the bill (S. 2259) with the recommendation that it pass. The bill consists of three sections, the first repealing Section 10 of the Act of June 2, 1879, which limited the operations and duration of that Act to the term of four years, as also that clause of the Appropriation Act of August 7, 1882, which confined the operations of the Board to cholera, yellow fever, and smallpox; the second rendering available for the work of the Board the unexpended balances of the appropriations heretofore made on its behalf, which lie to its credit on the books of the Treasury, amounting to about $124,000; and the third, authorizing the Board to use, of its unexpended conditional appropriations, the sum of $100,000, or so much thereof as may be necessary in the event of an epidemic during the fiscal year ending June 30, 1884.

Mr. Harris accompanied the bill with a report, which was ordered to be printed. The report discusses the action of the Board during the yellow fever epidemic of 1879, showing that the disease was actually stamped out in New Orleans, and confined to the limits of Memphis, and that "instead of the general demoralization and panic, with suspension of business, trade, and commerce, which pervaded the country in 1878, commerce and communication with the infected cities were REGULATED, NOT STOPPED, or even retarded to any considerable extent, and the general business of the country went on in its usual methods, and through its usual channels, without serious interruption. . . . In the opinion of the committee, the Board has accomplished much, and is capable of accomplishing highly important results of great benefit to the country; results which can be accomplished by no other agency."

The report adverts to the power of Congress to regulate commerce in respect to the importation of contagion as well as in respect to the importation of other things, such as of adulterated or impure drugs or medicines; but the committee does not deem it necessary to attempt to draw the line, or define sharply, exactly where the power of Congress to regulate commerce ends, and the legitimate exercise of the police powers of a State begins, as the act which the bill reported proposes to perpetuate does not conflict, or in any way interfere, with any State or municipal board of health, or its rules and regulations.

The report concludes as follows:

"If it be admitted, as it is believed all must admit, that the action and operations of the Board even tend to the preservation of life and health to any, however small the extent, such fact makes it eminently worthy of our support, and, in the opinion of the committee, it should be sustained with such powers and means as will enable it to perform its functions fully, promptly, and efficiently.

"When the memories of the fearful ravages of the epidemic of 1878 were fresh, both houses of Congress were ready to appropriate, and did appropriate, all that the committee asked for the purpose of endeavoring to find, if possible, a means of preventing the recurrence of this terrible scourge; but as the memories of the hundred thousand sufferers and the twenty thousand new-made graves of that period are fading from our minds, the committee has experienced more or less of difficulty in obtaining the appropriations necessary to enable the Board to perform the important duties which devolve upon it, and, indeed, found it impossible, at the last session, to obtain adequate appropriations.

"The practical question, as it appears to the committee, is, the country being now free from yellow fever and cholera, shall we use the necessary means to keep it so, or relax into indifference, withhold the powers and the necessary means to prevent their importation, and await the outbreak of another epidemic, which will cost the country hundreds of millions of dollars and thousands of the lives of our people, to awaken us to the importance of preventive measures, in which the committee believes we can find absolute security?"

NEW ORLEANS.

(From our Special Correspondent.)

POISONING BY CHLORAL.—A few days ago the daily papers reported a death from poisoning by chloral hydrate. In this case it is probable that the overdose was accidentally taken, as it was alleged that the victim was in the habit of using it to produce sleep. I do not know that there is any information in regard to the amount actually ingested.

Some days before this event, a case of poisoning by the same agent was admitted to a ward in Charity Hospital. The circumstances were as follows: A young gentleman took, with suicidal intention, a single dose of one hundred and sixty grains. When brought to the hospital, probably two to four hours after ingesting the drug, he exhibited the usual symptoms of contracted pupils, cool surface, and feeble pulse. He was treated with stimulants and warmth, and was promptly and completely relieved. Mr. Michinard, the intelligent ward student who conducted the treatment, administered coffee and carbonate of ammonium, but did not resort to strychnia.

Some time since a patient of a well-known practitioner here took ʒij of chloral hydrate at one dose, with no other effects than an uninterrupted sleep from 8 P. M. until 7 A. M.

Only one well-authenticated case of death from chloral hydrate has occurred in Charity Hospital. In this case the physician prescribed small doses to be repeated at stated intervals. By some means the patient got the bottle in his possession and repeated the doses so frequently that death occurred before attention was attracted to any unusual symptoms.

NEW YORK STATE MEDICAL SOCIETY.—The annual meeting of this Society will be held at Albany on Tuesday, February 6th, and it promises to be very largely attended, great interest centring in the Society's action in reference to the new Code which was adopted last year without previous notification to the members.

THE ARMY APPROPRIATION BILL, as reported to the Senate, abolishes the office of Assistant Surgeon-General, and appropriates $15,000 for the purchase of books for the Army Medical Museum.

THE NEW YORK COUNTY MEDICAL SOCIETY held a special meeting, which was very largely attended, last Monday evening. The meeting was called to obtain an expression of opinion from the Society in

reference to the new Code. DR. D. B. ST. JOHN ROOSA offered the following resolution:

Resolved, That the Medical Society of the County of New York approves of the amendment to the By-laws of the Medical Society of the State of New York, adopted at the annual meeting in February, 1882, and that we indorse the system of Medical Ethics therein substituted for the former one, especially because it leaves the matter of consultation to the discretion, the honesty, and the humanity of the individual practitioner. And, although we decline to instruct our delegates to the State Society, we respectfully recommend to our representatives that they labor for the further simplification of the system of Medical Ethics until it shall not contain specific rules for the regulation of professional etiquette, but only authorize procedure against conduct plainly unworthy of a physician and a gentleman.

After a spirited discussion, in which Drs. Roosa, A. H. Smith, C. R. Agnew, and Fordyce Barker advocated the resolution, and Drs. Austin Flint, Sr., J. T. Adams, Gerrish, and Dwyer opposed it, the resolution was adopted by a vote of 147 to 60 against it.

BOSTON QUARANTINE REGULATION.—An order of the Board of Health, dated January 25th, requires that on and after that date, all vessels arriving at that port from Baltimore, Md., shall stop at quarantine for examination by the port physician, and that all persons on board not protected from smallpox by recent successful vaccination or revaccination or previous attack of the disease, shall be vaccinated or subjected to a quarantine of observation. No vessel arriving from Baltimore shall proceed, nor shall her cargo, or any part thereof, be discharged, nor any person be allowed to go on board or to leave her while in quarantine, without the written permit of the port physician, who is authorized and instructed to take such measures with regard to the vessel as, in his judgment, the health of the city may require.

BANQUET OF THE ALUMNI OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.—The twelfth annual banquet of the Alumni of the Medical Department of the University of the City of New York took place at Delmonico's on Wednesday, January 24th. Dr. T. R. Varick, of Jersey City, occupied the chair, with the Chancellor of the University, Rev. Dr. John Hall, on his right. At a business meeting held before the dinner, the following officers were elected:

President.—Dr. A. E. MacDonald.

Vice-Presidents.—Drs. W. A. Hammond, Gouley, W. E. Ford, S. J. Clark, G. C. Jarvis, and G. J. Fisher.

Treasurer.—Dr. C. D. Varley.

PHYSICIAN IN ORDINARY TO THE QUEEN.—DR. WILSON FOX has been appointed Physician in Ordinary to the Queen in the place of the late Sir Thos. Watson, and Dr. Owen Rees has been appointed Physician Extraordinary, in succession to Dr. Fox.

THE COMMUNICABILITY OF PHTHISIS.—The Collective Investigation Committee of the British Medical Association is now collecting trustworthy evidence from the profession as to the contagiousness of pulmonary consumption.

MICHIGAN STATE BOARD OF HEALTH.—The regular quarterly meeting of the Michigan State Board of Health was held at Lansing, Mich., on January 9, 1883. The Secretary made his report of work during the last quarter. The following resolution was passed:

Whereas, This Board has long been laboring for the restriction and prevention of contagious diseases in Michigan, which depend greatly upon the existence of such diseases in other States and countries; and as this Board has been able to trace several outbreaks of diseases in this State during the past year to immigrant travel, etc., therefore

Resolved, That this State Board of Health urgently request our members of Congress to endeavor to secure the passage of a bill to appropriate $25,000 for the remainder of this fiscal year, and thereafter, at about the same rate, to enable the National Board of Health to coöperate with State and local boards of health, and quarantines, in efforts to prevent the introduction of contagious diseases into the United States, and their spread from one State to another.

The invitation to hold a sanitary convention at Reed City, some time in the spring, was accepted.

Analyses of apple-butter and of the tinned-copper such as is used to make wash-boilers, were presented. The apple-butter is often made in such "copper" boilers when they are new. The acid of the fruit attacks the tin, which often contains lead in dangerous quantities, and it is said that the tin lining is eaten off in one or two times using for making apple-butter. The analysis of the apple-butter showed distinct traces of lead and tin, and a faint trace of copper. That portion of the apple-butter in contact with the cap of the fruit jar in which the apple-butter was sent to the chemist, gave very strong reactions for zinc, doubtless derived from the zinc-cap which screws down upon the mouths of "Mason" fruit-jars. The specimen of tinned-sheet copper used in making "copper" boilers and other kitchen utensils was analyzed and the "tin" was found to contain a large quantity of metallic lead; about two-fifths of the "tin" was lead. From one square foot of such tinned surface, there was obtained the equivalent of 150 grains of metallic lead. The ordinary clothes-boiler, such as is used in our kitchens, if made of this tinned copper, would have 2½ ounces of metallic lead on its surface, an amount that must have a serious influence on persons who eat acid fruits and juices boiled in such a vessel. Dr. Hazlewood and Dr. Baker were requested to make an investigation into the subject of metallic poisoning by utensils for cooking and storing food.

The committee on legislation reported on an act requiring the registration of plumbers. Hon. James Heuston, M.D., Senator, spoke on the subject of the examination of new dwellings before occupancy, and the following resolution was offered by Dr. Baker and adopted:

Resolved, That the committee on legislation, etc., and the committee on buildings, public, private, etc., jointly, be requested to take into consideration the feasibility of the suggestion made at this meeting by Hon. James Heuston, M.D., for a State law requiring all plans for new dwellings to be submitted to the local board of health for approval.

The special committee on sanitary conventions reported that a sanitary convention was to be held at Pontiac, on Jan. 31, and Feb. 1, 1883. Among the subjects to be presented are, papers on the limitation and prevention of typhoid fever, the relation of the medical profession to public-health laws, on toy pistols, the dangers in dirt, and on the contamination of well-water.

The following resolutions (two of them having been passed before) were reaffirmed:

Resolved, That there should be required of all who are to begin the practice of medicine in this State an examination as to their qualifications.

Resolved, That such examinations by the State should be restricted to questions in demonstrable knowledge, as distinguished from questions of mere opinion.

Resolved, That, as a public-health measure, these two resolutions be referred to the President and Secretary, with a request to do what they can to further the objects of the resolutions.

FRENCH SCIENTIFIC EXPEDITION.—The sum of 8,100 francs have been granted by the Municipal Council of Paris to M. GEORGES POUCHET, Professor in the Museum of Natural History in Paris, for the expenses of a scientific expedition to be made this year to the Azore Islands.

LECTURES ON SPLENIC FEVER.—DR. W. T. COUNCILMAN will deliver two lectures on "Splenic Fever, as Illustrating the Relationship of Bacterial Organisms to the Production of Infectious Diseases," at the John Hopkins University, January 30 and February 1, 1883.

NORTHERN MEDICAL ASSOCIATION OF PHILADELPHIA.—At the late annual meeting of this Association the following officers were elected for the current year:

President.—Dr. J. T. Eskridge.
Vice-President.—Dr. Henry Beates, Jr.
Recording Secretary.—Dr. J. G. Heilman.
Treasurer.—Dr. L. Brewer Hall.

ETIOLOGY AND PATHOLOGY OF TUBERCULOSIS.—DR. FORMAD, of the University of Pennsylvania, has accepted the invitation of the Clinical Society of Maryland to deliver a lecture on the above subject on February 2, 1883.

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending January 20, 1883, indicate that diphtheria, erysipelas, measles, diarrhœa, typhoid fever, bronchitis, influenza, pneumonia, and tonsillitis have decreased in area of prevalence. There was no marked increase in any disease reported.

Including reports by regular observers and by others, diphtheria was reported present during the week ending January 20th, and since, at 19 places, scarlet fever at 21 places, and measles at 10 places. Smallpox was reported at Royalton, Berrien County (3 cases), January 17th.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 22 TO JANUARY 29, 1883.

WATERS, WILLIAM E., *Major and Surgeon.*—Detailed as member of Army Retiring Board to convene at Fort Porter, Buffalo, New York, February 2, 1883.—*Par. 1, S. O. 21, A. G. O., January* 25, 1883.

HEIZMAN, CHARLES L., *Captain and Assistant Surgeon.*—Will be relieved from duty in the Department of the Columbia, and ordered to report to the Commanding General, Department of the South, for assignment to duty.—*Par. 10, S. O. 20, A. G. O., January* 24, 1883.

KILBOURNE, H. S., *Captain and Assistant Surgeon.*—Leave of absence for one month, with permission to apply for an extension of two months, is granted.—*S. O. 218, Department of Dakota, December* 21, 1882.

PRICE, CURTIS E., *Captain and Assistant Surgeon.*—Detailed as member of Army Retiring Board to convene at Fort Porter, Buffalo, New York, February 2, 1883.—*Par. 1, S. O. 21, A. G. O., January* 25, 1883.

SKINNER, JOHN O., *Captain and Assistant Surgeon.*—Will report in person, at the expiration of his present leave of absence, to the Surgeon-General for duty in his office.—*Par. 10, S. O. 20, A. G. O., January* 24, 1883.

TAYLOR, MARCUS E., *Captain and Assistant Surgeon.*—Will report in person, at the expiration of his present leave of absence, to the Commanding General Department of the East, for assignment to duty —*Par. 10, S. O. 20, A. G. O., January* 24, 1883.

WOOD, MARSHALL W., *Captain and Assistant Surgeon.*—Will be relieved from duty in the Department of the East, at the expiration of his present leave of absence, and will report in person to the Commanding General, Department of the Columbia, for assignment to duty.—*Par. 10, S. O. 20, A. G. O., January* 24, 1883.

WOOD, MARSHALL W., *Captain and Assistant Surgeon.*—At expiration of present leave of absence, relieved from duty in the Department of the East.—*Par. 1, S. O. 15, Department of the East, January* 26, 1883.

WYETH, M. C., *First Lieutenant and Assistant Surgeon.*—Is relieved from duty at Fort Snelling, and will proceed to Fort Stevenson, Dakota Territory, and report to the Commanding Officer of that post for duty.—*Par. 1, S. O. 15, Department of Dakota, January* 18, 1883.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, OCTOBER 1 TO DECEMBER 31, 1882.

BAILHACHE, P. H., *Surgeon.*—Present detail continued until further orders, October 6, 1882. To proceed to Louisville, Kentucky, as inspector, October 13, 1882. Granted leave of absence for thirty days, November 10, 1882.

VANSANT, JOHN, *Surgeon.*—Granted leave of absence for twenty days, November 18, 1882.

HUTTON, W. H. H., *Surgeon.*—To proceed to Louisville, Kentucky, and assume charge of the Service, October 7 and 14, 1882.

MILLER, T. W., *Surgeon.*—To continue at present station until further orders, October 6, 1882.

WYMAN, WALTER.—To inspect keepers and crews of the Life Saving Service, October 5, 1882.

LONG, W. H., *Surgeon.*—To proceed to Detroit, Michigan, and assume charge of the Service, October 7 and 14, 1882.

MURRAY, R. D., *Surgeon.*—Having returned from service in the yellow fever epidemic in Texas, to report in person to the Surgeon-General, M.-H. S., December 4, 1882. Granted leave of absence until February 28, 1883, December 19, 1882.

FESSENDEN, C. S. D., *Surgeon.*—To proceed to St. Louis, Missouri, and assume charge of the Service, October 7, 1882.

PURVIANCE, GEORGE, *Surgeon.*—To inspect keepers and crews of the Life Saving Service, October 21, 1882.

SAWTELLE, W. H., *Surgeon.*—To proceed to New York, New York, and assume charge of the Service, October 7, 1882.

AUSTIN, H. W., *Surgeon.*—To inspect keepers and crews of the Life Saving Service, October 5, 1882.

FISHER, J. C., *Passed Assistant Surgeon.*—Present detail continued until further orders, October 6, 1882. To proceed to Alexandria, Virginia, as inspector, October 21, 1882.

HEATH, W. H., *Passed Assistant Surgeon.*—Granted leave of absence for fourteen days, December 28, 1882.

PORTER, F. D., *Passed Assistant Surgeon.*—To inspect keepers and crews of the Life Saving Service, October 5, 1882. To proceed to Evansville, Indiana, for temporary duty, November 21, 1882. To proceed to Charleston, South Carolina, and assume charge of the Service, December 21, 1882.

O'CONNOR, F. J., *Assistant Surgeon.*—To proceed to Norfolk, Virginia, for temporary duty, October 14, 1882. To rejoin his station (Detroit), November 4, 1882.

WHEELER, W. A., *Assistant Surgeon.*—Relieved of duty at Charleston, South Carolina, and placed on waiting orders, December 22, 1882.

ARMSTRONG, S. T., *Assistant Surgeon.*—To examine keepers and crews of the Life Saving Service, October 5, 1882.

BENNETT, P. H., *Assistant Surgeon.*—To examine keepers and crews of the Life Saving Service, October 5, 1882.

AMES, R. P. M., *Assistant Surgeon.*—Granted leave of absence for twenty-one days, November 23, 1882.

DEVAN, S. C., *Assistant Surgeon.*—To examine keepers and crews of the Life Saving Service, October 13, 1882. To inspect unserviceable property at the San Francisco Marine Hospital, October 20, 1882.

KALLOCH, P. C., *Assistant Surgeon.*—To inspect keepers and crews of the Life Saving Service, October 5, 1882.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked,

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

SOME OF THE PERILS TO LIFE FROM PREVENTABLE DISEASES.

The Anniversary Address before the Medical Society of the State of New York, at the Seventy-seventh Annual Meeting. Delivered at Albany, February 7, 1883.

BY HARVEY JEWETT, M.D.,

OF CANANDAIGUA, N. Y., PRESIDENT OF THE SOCIETY.

GENTLEMEN: "Life and health may be regarded as the sum of all good to the human race." The health, happiness, and prosperity of mankind, must be intimately and inseparably connected with, and dependent upon, their sanitary condition. Upon this to a great extent rest the foundation and superstructure of our national well-being.

Men perish from bad air, impure water, and unwholesome food, because they are ignorant of that which constitutes the danger in these essentials of life. They prefer to be governed by their appetites and passions, rather than to be controlled by reason and hygienic laws that must be obeyed, or the penalty of disobedience be incurred. Our occupation would be diminished in an essential degree if the art of preventing disease was thoroughly understood and universally practised.

The people are slow to apprehend the dangers that arise from trivial causes and from habits of life in which they have indulged for years, because they are unable to trace any direct connection between obscure and indirect causes and positive results. They are also unwilling to accept the fact that disease and death may result from their own carelessness and uncleanly practices. The excessive civilization of modern times, the æstheticism of the age, have blinded our eyes and perverted our judgment, and led us astray from the habits of primitive times that gave our ancestors more vigorous constitutions and more stalwart frames than we of this generation can boast.

The subject is one in which all are interested and intimately concerned, and I rejoice to know that competent medical men are making the most scrutinizing investigations in relation to sanitary questions, and recording the fruits of their labor for the benefit of the people. Never before in the history of this country were the people and the profession so much aroused to a sense of their situation and danger, and an earnest seeking after a radical reformation in relation to the practical application of knowledge to the affairs of life. I trust that the time is not far distant when a large class of diseases which now afflict the human family will be eradicated, or so far mitigated in their severity and danger, as to be comparatively harmless.

There are some conditions which greatly affect the health of a community over which sanitary work has little or no control. The temperature and moisture of the air greatly influence the health of the people. Sudden and marked variations in temperature, excessive heat with humid atmosphere, enfeeble the system, diminish the vital force, and render the individual susceptible to the influence of any prevailing epidemic. But it is not with these agents that we are to deal in endeavoring to check the progress of disease, inasmuch as they are largely beyond the reach of human intervention. It is to certain combinations of heat, moisture, and animal or vegetable decomposition, which occur either in the course of nature, or more often as a sequence to man's careless and slovenly habits, that we are to look for the conditions, even though we may not always say the cause, of disease.

The spirit of scientific medicine is, indeed, progressive. Unbaffled by the records of previous failure, and undaunted by that which seems to be the impenetrable darkness of mystery, the search into the etiology of disease continues; and gradually as persevering efforts are rewarded by success and light, though it be but dim and partial, illumines the search, preventive medicine makes more urgent demands upon the scientific capacities of the physician.

Far more is demanded from the practising physician of to-day than was requisite a quarter of a century ago. Then, a common school education, a fair knowledge of anatomy and physiology, a smattering of chemistry, an acquaintance with the principles of medicine and surgery, and, above all, a familiarity with the drugs of the pharmacopœia, were the endowments requisite for a well-qualified practitioner of medicine. Men thus equipped may even to-day be of great service in their profession, recognizing with acuteness the nature of disordered bodily conditions, and applying, with rare skill and excellent common sense, the remedy suitable for each case.

But there is another work which cannot be accomplished by a few, even though they be energetic and earnest, but which must devolve upon the general practitioner, especially in the country districts.

Our National and State boards of health have done in the past, and are doing at present, most excellent and telling work, and we look with just pride especially upon that achieved by our own State board. Yet to be successful in their work of heralding danger and preventing disease, the State boards of health must be backed by efficient town boards, and especially, I claim, by the efforts of individual practising physicians. A difficulty arises here, and it is to this point that I wish to draw special attention; viz., to the inability of the majority of practising physicians to properly advise their patients and patrons in sanitary matters, owing to their ignorance of the first principles of sanitary science.

The finger of investigation points to certain defects in drainage, water supply, or ventilation, as the prolific source of disease. How many physicians are able to recognize these defects with certainty, or to give competent advice for their remedy? How many health officers, especially in the smaller settlements, are versed in the principles of natural philosophy which lie at the foundation of all drainage and ventilation? Surely the work of inquiry into the etiology of disease demands that the investigator be equipped with more than a surface knowledge of chemistry, and be more than a novice in the use of the microscope and its valuable accessories.

I claim also, that the physician, who is not only to minister to the wants of the sick, but in his nobler work, to protect the health and lives of others, should possess as a foundation for the superstructure of his strictly medical education, an accurate and serviceable knowledge of the principles of chemistry, natural philosophy and the natural sciences generally. This education should, and can be made preliminary to the work of the professional school. That many physicians graduate with this needed preparation, and thoroughly

equipped in all respects, is a matter for congratulation. But those do not compose the rank and file of the profession in this country to-day. The demand is for more thoroughly educated medical men and women, and that demand must be met by men taken, not directly from the farm, the work-shop, and the common school, but by those favored with the rigid mental discipline of academy or college, and well grounded in the principles of natural science.

Right here, I suggest that general practitioners thus thoroughly educated, and mingling as they do, with all classes of people, seeing as they do, every form of disease, are the sources from which are to flow into the treasury of knowledge that vast accumulation of carefully recorded facts, from which great truths are to be deduced. Only minds well trained are equal to the great task of correctly observing and noting the phenomena of disease and its varied surroundings. The advantage to medical science, were all the rich stores of experience already gained by workers in this great field given to the world through the medical journals, instead of being buried with the possessor, as is too often the case, cannot be over-estimated. How much greater would that gain to medical knowledge be, were the observers of these phenomena trained to more exact habits of noticing and recording their experience. Particularly in country districts, are the opportunities unusually favorable for studying the laws which govern the origin and spread of contagious and infectious diseases, because of the comparative isolation of the inhabitants, and hence the more urgent need of better educated medical men, who, because thus better prepared, will be more desirous, as well as better able to assist in the contest against preventable disease.

It would be impossible to discuss the perils to life from preventable diseases and protection from those perils without briefly referring to that theory of the origin and spread of contagious maladies now so widely known as the germ-theory. Certain minute vegetable forms of life, known as bacteria, of various forms and possessing the power of rapid multiplication, and of being carried in the atmosphere as spores, are to-day claimed by many competent observers to be the active agents in the causation and spread of contagious and infectious diseases. So captivating is the thought of accounting for disease in this simple way, that some observers, as well as some who are mere theorists, have, I fear, suffered their enthusiasm to get the better of their cool, calculating judgment. Ever conflicting and positive statements, which are the fruit of carefully conducted experiments to determine the relation of this or that particular form of bacterium to this or that disease, continue to bewilder the mind of the conservative medical man, as well as to mystify the masses of scientific thinkers outside the ranks of the profession. At present it becomes us to receive with caution the reported results of all such experiments, and the theories formulated therefrom, and while we accept some things as proven relative to this theory of vegetable disease-germs, to bear in mind that much which is claimed by some, may still be fairly placed in the realm of the unproven, though perhaps eminently probable. The importance of determining whether these vegetable germs found in connection with certain contagious diseases are the cause or effect of the diseased condition cannot be over-estimated, especially as we enter upon the domain of preventive medicine.

In turning our attention to that which most threatens and imperils human health, if we permit ourselves to be guided by a prevailing public sentiment, we shall not hesitate long in attributing to defective sewerage a large share of the responsibility. So wide-spread has become the impression that sewer gas, so called, is at the bottom of most of the ills that flesh is heir to, that the mere words have coupled with them a deathly meaning. As civilization advances and the masses of our population congregate in cities, a system of underground sewers has supplanted the primitive vault, while the water-closet and the stationary washstand connected therewith have become an almost indispensable convenience. These underground sewers being intended to receive and convey away not only the house sewage, but also the rain-wash of the streets, have a capacity equal to the heaviest rain-falls. We have, then, a subterraneous cavern of great length and with numerous branches of smaller size, the floor of which is partly covered, or at certain times in the day entirely covered by a slowly moving stream of such horrible filth as is sickening to contemplate. The air filling the space above being, as is usually the case, confined, becomes surcharged with the emanations from this decomposing mass, and is what is known as sewer gas, or, more properly, sewer air. Its composition, as is well known, is variable; ammonia, sulphuretted hydrogen, carbonic acid gas, and various organic impurities being its main ingredients. That this gas, not even betraying its presence by an odor, is oftentimes an uninvited guest in our dwellings no one will deny; just how often no one can say. Strange to say, however, the door is frequently left open for its entrance, though heavy bolts guard against other dangerous intruders. Old and defective house-pipes and unserviceable though well-meant traps not unfrequently unite the elegant chamber above with the filthy cavern below, and ventilation of sewers takes place after a fashion not altogether desirable.

Gaining entrance, what are its effects, if any it has, upon the inmates of the house? To one reading or hearing of the direful effects of sewer gas in causing or spreading diphtheria, scarlet fever, and typhoid fever in our crowded cities, it might not unnaturally seem that, were this curse once abolished, there would be no more diphtheria and scarlet fever. Unfortunately for this theory, these scourges do flourish, and that, too, malignantly, in country districts, where—as far as can be discovered—the hygiene is good, and no sewer gas exists. It cannot be denied that filth poison even in in these cases may lurk somewhere undetected.

Further, it has not been proven that the air of sewers, when inhaled even in large quantities, has any immediate injurious effects. Plumbers and scavengers, who inhale it directly from the sewers, do not in their persons give proof of any fatal effect, nor do they, according to statistics, suffer especially from the diseases before mentioned. Exposed as they are to its influence during working hours, and emerging soon into purer air, it has been claimed, and justly too, that they are really less liable to injurious effects than those who breathe it, though more diluted, yet in the confined air of a bedroom while in the sleeping condition, when the vital forces are less resisting. Inspired in this way day after day and night after night, and especially when delicate women and children are the subjects, the effect of sewer air is to lower the vitality of the system, to predispose it to disease, to render more virulent any malady that may supervene, and to induce a feeling of exhaustion and a gradual decline of health.

It is claimed by those who support the germ theory that diphtheria and other contagious diseases are spread from house to house in sewered cities largely by the agency of this sewer air; that in this sewer air float germs which have been thrown off in the excreta of the patients; which germs, coming into conditions favorable for development in the warm and moist air of the sewer, there multiply, and are so diffused. Especially is it claimed that the conditions for the development of these germs are unusually favorable in sewers where but a small portion of the surface

is covered by the sewage, and where arrested sewage and moisture abound. It is also claimed that these germs so multiplied have gained an additional virulence from being so propagated, and that they are even more contagious than would be the fresh excreta of the diseased person.

Pasteur has shown that the bacilli of anthrax and of fowl cholera when cultivated and exposed freely to the action of oxygen lose their virulence, and that they may be safely inoculated, producing thereby a mild form only of the disease. Grown under different conditions, viz., in a confined atmosphere, and deprived of a full supply of oxygen, these bacilli retain their original poisonous properties. It may be so with the germs of diphtheria, if, indeed, there be such, and of typhoid fever, that grown and multiplied in the confined atmosphere of the underground sewer, and deprived of a full supply of oxygen, they may become doubly poisonous.

In the present uncertain state of the evidence concerning the agency of sewers in originating or spreading disease, some reflections upon the proper action to be taken by those interested in sanitary science may not be out of place here.

First, it may be well to refresh our memory with the recorded failures of numerous investigating committees to trace, in time of epidemics of diphtheria and scarlatina, any direct connection between the favorite localities of the disease and defective plumbing. Indeed, the plumbing in such cases has been reported to be exceptionally good by those competent to judge.

On the other hand, we are in no danger of forgetting those countless reported instances where foul air is indisputably connected, in some way, with the visitations of pestilence. It is well to keep fresh in our minds also, that the breathing of foul air, especially at night, induces a condition of malaise, in which the vital forces are greatly lowered, and in which condition what might have been but a trifling ailment suddenly assumes a serious or a fatal aspect.

As has been before stated, it appears to be proven that a noxious microscopic organism may be changed to one innocuous under favorable conditions; and *vice versa*, that one innocuous may become virulent. It has been shown also that the bacteria found in the mouth of a healthy person, or one suffering from a simple sore throat, cannot be distinguished, microscopically, from those found in the diphtheritic membrane. It is quite possible that under favorable conditions, as in an atmosphere of sewer gas and in a depraved bodily condition, a simple sore throat may become malignant and fatal in its results, owing to some change in the character of the vegetable organisms. In this way it may be that diphtheria appears as an endemic.

Bearing all these facts and possibilities in mind, it seems to me that as a profession we are warranted in urging a very *safe* course to be pursued in reference to this whole subject of sewers and sewer air in dwellings. It is safe to give ourselves and our patrons the benefit of the doubt, and whether or not diphtheria and allied scourges are generated or conveyed by sewer air, it is best to give it no opportunity to poison our bodies while asleep. I do not deny that plumbing may be made secure by a suitable arrangement and ventilation of soil-pipes and traps, and by great care in the placing of house fixtures. Nevertheless, I protest against allowing any possible connection between the sewers and sleeping apartments. Let the stationary washstand be entirely, as I am happy to know it has been partially, banished from the bed-chamber. Moreover, let the arrangement of water-closets be planned with the strictest regard to separation from living or sleeping apartments, and, best of all, let them be entirely disconnected. Without committing ourselves to a belief in the theory that it is the bearer of countless disease germs, I believe that there is sufficient evidence already that sewer air does enter dwelling houses, often, too, when the assurance of the plumber has lulled to false security, and that its effects are extremely deleterious, to warrant such decided advice and action as that just advanced.

The system of separate sewerage as adopted at Memphis, when properly carried out, appears to be also far superior in a hygienic point of view to the combined system. By this arrangement the house sewage is provided for in pipes of small size and of perfectly smooth calibre, while the rainfall is carried off by surface drains. In this way may be avoided the huge vault, whose full capacity is rarely tested, and which serves as a storehouse for noxious gases.

The relation which the character of the soil selected as the site of habitation bears to the health of inhabitants has not, I think, received the attention which its importance demands. The matter of soil drainage may be carefully attended to, and no damp cellar nor defective sewerage be found to account for the devastations of disease. A dry cellar is not, however, necessarily one devoid of danger, and because dry thus rendered incapable of affecting the health of occupants. Competent observers have demonstrated that the atmosphere does not end where the earth begins, but that ground air contained in the interstices of the soil has peculiarities of its own. It has been shown that it contains a large proportion of carbonic acid gas, as well as noxious gases and organic matter in abundance which come from the decomposition of animal and vegetable substances, either beneath or upon the surface of the earth. There is, moreover, a circulation of this ground air by which it tends to disseminate itself into the external atmosphere and in a horizontal direction also. The presence of any decomposing organic body, either beneath or upon the surface of the earth, must necessarily taint this air, and the results of such decomposition thus be disseminated. The presence of cesspools, graveyards, and garbage heaps may thus not only prove deleterious to the drinking water as is generally acknowledged, but also to the ground air. This ground air obtains easy access to our dwellings, and is especially invited into them in cold weather when the warmth above makes a flue of the cellar floor, unless it be properly protected, and so the ground air is attracted upward.

If it is true that so-called disease germs do not die with the death of their victim, but survive for many years buried in the earth, this matter of ground air opens with a new interest. Pasteur asserts that he has found the germs of anthrax or splenic fever in the soil about the buried carcasses of animals which had been dead twelve years, and that with these he has reproduced the disease. It may be that other contagious diseases may retain their virulence about the body of their buried victim for some time, and be disseminated in the air or water of the surrounding earth. Is there not sufficient *possibility*, to say the least, of the truth of these assertions to warrant more care in selecting the site of a dwelling and guarding its surroundings? Does it not savor of discretion, at any rate, to see carefully to it that cemeteries do not encroach closely upon places of habitation, and that cesspools be utterly banished from the proximity of dwellings? Quite as important to consider also, is the matter of ground-water in relation to building sites. Though there be no putrescent animal or vegetable matter in the vicinity, yet the constant or occasional pressure of an oversupply of water in the soil about a dwelling is deleterious to health. Especially has a direct connection been traced by careful observers between a superabundance of ground-water and the prevalence of

consumption in a locality. It therefore becomes a matter of no slight importance to avoid such localities if there be a tendency to pulmonary trouble, or if necessary to build thereon, to carefully drain the cellar and surrounding ground with properly constructed drains. It has been noted, and I think correctly, that the children of a household are the first to feel the deleterious influence of a damp or otherwise unwholesome dwelling-site, and that their ill-health may often be taken as the signal of danger and the index of the unsanitary condition of the neighborhood.

The watchful and conscientious family physician will be alert to discover such possible causes of disease. If he be more than a mere administrator of drugs, an acute observer of various natural phenomena, and well posted in the principles which underlie all successful drainage, he will undoubtedly succeed many times in saving or prolonging lives which otherwise would have soon been sacrificed to unsanitary surroundings.

The sanitary condition of drinking water holds a front rank among the influences which determine the healthfulness of a locality and its inhabitants. It needs no argument to prove the disastrous effect of contaminated water when taken into the animal economy. By contaminated, I mean particularly water affected by sewage and excremental filth, although it is quite possible that water polluted from other sources, as from decomposing vegetable matter, may be deleterious to health. Just as sewer air may escape undetected into living apartments, its presence betrayed by no foul smell, and meantime do its deadly work in slowly poisoning the frail bodies of its victims, so may well water be taken into the body repeatedly, the consumer never suspecting, from its odor, or appearance, or taste, that it contains the potency of disease. A water rank with the smell and taste of vegetable decomposition may be spurned as unfit for use, yet another water, though of pleasing appearance and taste, may be for that very reason more deadly in its working.

It has been proven by too many authenticated instances to admit of doubt that typhoid fever may be communicated by water into which has percolated through the soil dejecta from an infected patient, although the privy vault or other place of deposit may have been some distance away. The deodorizing properties of the earth have often availed to make such water not unpalatable. The abominable and criminal carelessness in disposing of refuse, which is so often seen by all of us among people who know better, as well as among those who do not, needs no comment. But in our larger villages of many years' standing, where there is not a system of sewerage, a condition of soil is liable to exist which is full of danger, and which, because of its gradual development, is apt to be overlooked. I refer to the continued soaking of animal and vegetable filth into the soil upon which the town is built, owing to the multiplication of cesspools and surface drains, until, after many years, the whole ground has become infiltrated with organic products of foul origin. In such a soil well water can no longer be depended upon for purity, even though there be a strict regard paid to the separation of the well from places of waste deposit. Eventually pestilence will visit such hot-beds of disease, and many theories but the right one will be advanced to explain a so-called terrible "visitation of Providence." Diphtheria and scarlet fever in such communities assume a malignant type from the first, and linger long without abating, whereas, had the hygienic surroundings been good the above-mentioned diseases might have existed, but not in so destructive a form.

Surely, the abandonment of wells as sources of drinking water in such instances will commend itself to every sensible mind as the only course to be pursued.

The utter disregard of all rules of hygiene, and even of decency, which is too frequently seen in the discharge of the refuse of a great city into the same body of water from which that city or a near neighbor receives its supply of drinking water, is beginning to receive the attention which its importance demands. A few more epidemics of disease, and large mortality lists, it is to be hoped, will secure appropriate legal enactment to control such action on the part of corporations.

Time would fail to point out the innumerable abuses which human nature heaps upon itself in the discharge of the functions of daily life. We have but referred to some of the dangers incident to foul air and foul water, and a few of the many ways in which that danger is incurred. The neglect of sunlight and exercise, improprieties both in food and dress, are all factors in causing disease of no mean account in making up the sum total of preventable diseases. It has been estimated that one-third of all the sickness and mortality in this State for a year is preventable.

No reminder is needed that pulmonary phthisis is a disease which, with lamentable frequency, is inscribed upon the death certificate as the chief and determining cause of death. Though not entirely preventable, yet I believe that thousands of lives might be annually saved were the medical profession more disposed to study the atmospheric and telluric, as well as other influences which favor its development in the predisposed, and to impress their intelligent views upon destined victims with an earnestness which should admit of no wavering as to the course to be pursued.

I would not question the correctness of certain observers who have announced the presence of a peculiar bacillus in the lungs of phthisical patients, but should hesitate to pronounce it a cause rather than an accompaniment of the disease. The affirmed contagious nature of the disease appears of minor importance and quite open to suspicion when the clinical histories of vast numbers of cases are compared. I venture to assert that there is vastly more good to be accomplished by careful attention to climatic influences and habits of life than by antiseptics and cod-liver oil with hypophosphites. So pressing does the need appear of more thoroughly educated and studious men to stand as guardians of the public safety in every village and hamlet of this vast country, that I cannot, in conclusion, but revert somewhat to the thought which found utterance at the opening of these remarks. We want men in every country district of the land, as well as in every city, who shall be worthy the name of professional gentleman. Who, in general information and culture, though mingling largely or solely with the uneducated, shall be among them and not of them, and who, by reason of the power which knowledge and mental discipline gives, shall be leaders among the people in every good enterprise, and give a dignity to and a respect for the profession of medicine which, I regret, it does not fully possess to-day. Under the present system of medical education, I fail to see a prospect for the achievement of this desirable result. So long as men are permitted to graduate from some of our most reputable medical schools, to enter the ranks of the regular profession, so poorly equipped for life-service in a profession which demands the very best of talents and preparation, we cannot wonder that quackery continues to flourish and to receive the patronage, humiliating to confess, of some who are on other subjects the most enlightened.

When the requirements for entrance upon the study of medicine in our medical schools are made vastly higher, when the teaching is better systematized and a

longer time in preparation is insisted upon, not only will the profession rise higher in public estimation, but there will then be opportunity for the teaching of hygiene and some other departments, for example that of legal medicine, which now are as a rule sadly neglected.

Thanks to earnest workers and great facilities for education, both at home and abroad, the profession of medicine in America shows a very bright side as well as the dark one to which I have alluded. Scattered through the entire country are men at work who are shedding lustre upon their profession, and others to be numbered by the hundred, who in a quiet way are doing all that is possible to magnify their calling and to induce the respect of mankind.

When such men take the places universally of those who, it is to be regretted, by no means adorn their profession, we shall hear fewer denunciations of doctors, which we know sometimes to be too well deserved, but which reflect none the less surely upon the profession as a whole, because incurred by some unworthy member who is yet in the ranks by the tolerance both of his professional brethren and the law of the State.

No monomaniac will then be permitted, in the public prints, to flaunt his maledictions upon "physic and physicians" as "twin scourges of humanity," because of the respect which the medical profession will everywhere command. Though less in numbers, because of the necessities of the case, when preventive medicine shall have attained its destined eminence, we shall hold a prouder position, and be more than ever the benefactors of the race.

PAPILLOMA OF THE BLADDER; OPERATION; CURE.

BY JOSEPH RANSOHOFF, M.D., F.R.C.S. ENG.,
PROFESSOR OF ANATOMY AND CLINICAL SURGERY IN THE MEDICAL COLLEGE OF OHIO.

(Read before the Cincinnati Academy of Medicine.)

TUMORS of the urinary bladder are of such rare occurrence and present such varied points of interest in their recognition, prognosis, and therapy, that every example is worthy of careful record. Pain, hemorrhage, and disturbances of the functions of the organ are common to many affections of the bladder, and singly and collectively are scarcely more than aids to the safer methods of diagnosis by physical explorations. Unfortunately even these, together with a most careful examination of the urine, fail to throw sufficient light into some cases in which the rendition of a positive diagnosis prior to an operation or death is simply impossible. The symptoms of calculus, neoplasms, tuberculosis, and prostatic hypertrophy are all gradually developed, and as clinical features of these affections, hæmaturia, pain in the penis, perineum and rectum, and purulent, fetid urine are frequently encountered. In all of these diseases, time brings with it a thickening of the vesical walls. If the examination of the bladder with the searcher give negative results as to the presence of a stone, and particles of a tumor can not be removed from the eyes of the instrument, the obscurity of the case is only enhanced, particularly if the rectal exploration reveals nothing more than the thickened condition of the bladder or an hypertrophy of the prostate. Even with due consideration to the age of the patient, and the presence or absence of cachexia, to the family history and inherited predisposition to one or other affection, the nature of certain—fortunately rare—cases can not be revealed. I beg leave to present the following illustrative case, which also clearly demonstrates the utility of cystotomy for the relief of urgent symptoms and as a most estimable aid towards the establishment of a diagnosis.

CASE.—In December, 1880, I was called to Union City, Indiana, to see I. M., æt. 26, who had for two years been suffering from an obscure affection of the bladder. With the exception of a slight tendency to tuberculosis the family history is good. The patient although ready to admit that he has had numerous opportunities to contract a gonorrhœa, strenuously maintains that he has never suffered from it. During the first six months of his sickness he observed a desire to urinate more frequently, and the necessity of emptying his bladder from two to four times during the night. The micturition was attended with considerable pain, particularly towards the close of the act. During the last year the pain has been constant, and has necessitated the exhibition of from one to four grains of morphia daily. The pains experienced were at first seated in the perineum and at the root of the penis. Recently they have extended to the glans and the rectum. Within a year severe hemorrhages have supervened four times, and small quantities of blood are lost weekly.

At the time of my first examination the patient was unable to leave his bed, and presented a yellowish tinge of the skin and a body greatly emaciated. The odor in the room convinced me of the existence of some grave affection of the bladder. The pain in the penis is at times so severe that nothing but firm rubbing of the part affords relief. The pain in the rectum is likewise very severe, and becomes excruciating when a hardened fecal mass is expelled. The patient finding it unavoidable to urinate every ten or fifteen minutes holds a urinal between his thighs constantly. The urine when passed is thick and fetid; alkaline in reaction, and speedily deposits a thick ropy sediment which frequently contains the formed elements of blood. The introduction of the sound was so much dreaded on account of the painfulness of previous examinations that the patient was thoroughly etherized before an instrument was used. No obstruction was encountered in the urethra. When the Thompson's searcher had entered the bladder and was rotated it revealed posteriorly and to the left a roughened condition of the bladder which was sufficiently pronounced to interfere with the complete rotation of the instrument. With the finger in the rectum, an enlargement of the prostate was found, and when a second finger was introduced the greatly hypertrophied wall of the bladder could be felt between it and the sound. A prolonged examination failed to reveal the existence of either a calculus or calcareous incrustations. Before removing the instrument, the capacity of the bladder was determined by an injection. Under moderate pressure it held a little less than four ounces.

Early in January, 1881, the patient was brought to the City and occupied a room at the Cincinnati Hospital. During the four weeks that I had not seen him, his general condition had become worse, and his sufferings had augmented to such a degree that unless morphia was administered in one-third or half-grain doses, relief could not be obtained. Evening temperatures, followed by night-sweats had supervened, and a rather copious purulent discharge from the urethra had appeared. Repeated physical examinations failed to throw any further light upon the nature of the case. The great tenderness of the posterior vesical wall and of the prostate when palpated through the rectum, and the suffering produced by each stool led the patient to the belief that his entire trouble sprang from the lower portion of the bowel. In the absence of stone, and without the previous existence of a gonorrhœa to account for the violent cystitis which had developed, the diagnosis, it appeared to me, rested between a tumor of the bladder and tuberculosis of the genito-urinary apparatus. The urethral discharge, the marked sensitiveness of the neck of the bladder, the prostatic enlargement, the decided hectic, and rapidly increasing emaciation were strong factors pointing to the existence of tuberculous deposits about the neck and base of the organ. On the other hand, the absence of tuberculous manifestations in the lungs and in the testicles militated strongly against the presence of a primary tuberculosis of the parts involved in the disease. When tubercles are found in the mucous membrane of the bladder, they are as a rule associated with similar deposits in the vesiculæ seminales, testicles, and particularly in the kidneys. Indeed the existence of a tuberculosis limited to the bladder is so great a rarity, that I have been able to find no other instance than that of Prescott Hewett recorded.

The recurring expulsion of pure blood from the bladder, and its presence in smaller quantity in the urine at short intervals, the pain radiating from the perineum to the penis and rectum, and the inability to sweep the fundus and sides of the bladder with the beak of the instrument, were the prominent symptoms and physical signs that led to the suspicion that a vesical growth was at the bottom of the violent cystic inflammation. Nevertheless, the negative result which was obtained by resorting to Volkman's method of "bimanual exploration" of the bladder made me doubt the presence of a tumor.

Recognizing the futility of internal medication, the impracticability of washing out the bladder on account of the suffering which it entailed, and the inroads which the disease was rapidly making on the general health of the patient, I determined to resort to cystotomy in order to ameliorate his condition and to permit the removal of a neoplasm if one should be found.

Operation (Jan. 19, 1881).—The patient having been placed under the influence of ether, a large grooved staff was introduced into the bladder and the incision usually made for lateral lithotomy practised. When the bladder was opened and the finger introduced, it at once came in contact with a fleshy mass situated on the posterior wall of the viscus to the left of the median line. As nearly as could be determined by circumventing the growth with the finger, it had attained the size of a small peach. It was not in the least movable, but was firmly attached by a broad base to the vesical wall. On this account, its removal with the écraseur or wire-loop was wholly out of the question. Guided by the finger of the left hand, I was enabled to introduce one of Volkman's sharp spoons and without any considerable difficulty break down by a scraping process the tumor, which came away in shreds and in larger masses. The great friability of the tumor unquestionably added to the comparative facility with which this part of the operation was accomplished. Not until I could feel quite a distinct excavation in the place where the tumor had existed did I desist from the scraping process. It is almost needless to add, that the cutting edge of the spoon was always guided by the finger, and that the manipulations necessary to the levelling of the growth were at no time violent. The hemorrhage at the time of operation was very copious, but after its completion it yielded readily to injections of hot water.

Considering the miserable condition of the patient prior to the operation, his recovery from its immediate effects was very gratifying. During the first two days the contact of the urine with the clear surface of the wound gave rise to considerable suffering, but after granulations appeared this source of pain disappeared. During nearly two months the perineal wound remained open and the bulk of the urine discharged through it. The pain in the penis and perineum had passed away, and the desire to urinate had become less frequent. Notwithstanding frequent and copious injections made into the bladder through the perineal aperture while practicable, and later on through the penis, the urine continued alkaline for three months after the closure of the wound and the patient experienced the necessity to empty his bladder from four to six times in the course of the night. The pain in the rectum likewise continued for nearly six months after the operation and at times was so severe that I was repeatedly accused of having operated in the wrong region. The continuance of these symptoms unquestionably depended upon the delayed reduction of the inflamed mucous membrane to its normal condition, and upon the substitution of a slowly healing ulcer in the place of the tumor. Quite a year elapsed from the time of operation before the urine passed by the patient was normal in character, and before he could pass six or seven hours in continuous sleep. The tedious convalescence, which was extremely embarrassing in this case, corresponds with the experience of other operators in similar cases.

The rasping process which in this particular case answered so excellently for the removal of the growth, unfortunately excluded the possibility of any satisfactory investigation of its histological character. Examinations of a large number of particles removed by the spoon revealed the presence of numerous elongated bundles of a loose connective tissue, which were occasionally found to

terminate in rounded-off points like those encountered in the papillomata springing from other mucous membranes, and invested upon their exterior by one or two layers of low epithelial cells. The most marked feature of the teased specimens, which were the only ones that could be obtained, was the great predominance of large capillary loops and meshes, which accounted readily for the frequently recurring hemorrhages. These factors in the histological construction of the tumor, and its non-recurrence after a lapse of two years have almost convinced me that it would properly be classed with the non-malignant fibrous papillomata. Considerable doubt may justly attach to this disposition of the tumor, since papilloma vesicæ rarely appears singly, and speedy reproduction is as much a characteristic of the vesical as of other villous growths. Thus W. Alexander[1] reports the case of a woman from whom he removed twelve fungous growths *per urethram* and was forced to repeat the procedure twice within less than two years. In a very able article upon this subject, Dr. Robert S. Hudson[1] records a case in which the bladder was found to contain eight distinct growths which might easily have been removed by écraseur, evulsion, or scraping.

For reasons that are patent, the diagnosis and treatment of vesical neoplasms must vary materially according to the sex of the individual. The dilatability of the female urethra, its close anatomical relation to the vagina, and the facility with which instruments can be introduced into it, render the diagnosis and operative treatment of these tumors in the female, a matter of comparative simplicity. Hence it is not remarkable that of the 16 cases of operations for cystic growths collected by Gross,[2] 12 were in females and only four in males. To the former number such large contributions have been made in recent years that the list that could be gathered would rather exceed than fall short of fifty. Over a year ago, Stein[3] was able to collect 23 opera-

tions upon females practised either through the urethra or by incision through the vesico-vaginal septum.

Excepting the worse than useless, hazardous, and unsurgical attempts of French surgeons like Civiale and Mercier to crush these growths in the male bladder with the lithotrite, they were practically considered inaccessible to operative interference until the celebrated case of Billroth levelled the barriers which confined surgeons to palliative measures alone. In June, 1874, this intrepid operator successfully removed from a boy twelve years old a large myoma from the posterior wall of the bladder by a suprapubic incision, after a preliminary lateral operation through the perineum had confirmed the diagnosis, and convinced the operator that the size of the tumor precluded its extirpation through the perineum. Volkman operated in an almost identical case of myoma vesicæ by combined perineal and suprapubic incision, with the result, however, of causing the death of the patient from peritonitis on the fourth day. In the case of Marcacci, the interior of the bladder was illuminated with magnesium light, the rays having been projected from a concave mirror. The tumor recognized by this procedure was removed by suprapubic incision. While the operation was reported as a complete success on the tenth day, the patient succumbed at the end of two months to the exhaustion consequent upon urethral fistulæ. From a rather careful examination of the literature of this subject, I have been enabled to collect a series of fourteen cases (including my own) of vesical tumors operated on in males, which may be seen in tabulated form on page 155.

It will be seen that seven recoveries resulted in eleven cases in which the perineal section was practised; three such operations resulted fatally, and one led to a partial success. Of the three suprapubic operations, two terminated fatally. When it is remembered that the recognition and operative treatment of vesical tumors are as yet in their infancy, the results that have already been obtained are exceedingly satisfactory. The fact that in the fatal cases an operation was not resorted to until the strength of the patients had been exhausted by long suffering, unquestionably has increased the death rate after surgical interference. It can scarcely be too soon to regard it as a good rule of practice that perineal cystotomy, preferably the median, as suggested by Thompson, should be performed in every case of suspected tumor of the bladder in which the symptoms are not affected by palliative means, and in which the presence of malignant disease can be excluded. Should the operation be unrewarded by the detection of a neoplasm, or should it be found that its removal can not be accomplished with safety, the operation would still benefit the patient by giving ready exit to the urine, mucus, or pus, and effectually overcoming the painful tenesmus that is so often encountered in chronic cystitis, no matter from what cause.

SODIUM BICARBONATE IN THE LOCAL TREATMENT OF ACUTE TONSILLITIS.

By J. O. SKINNER, M.D.,
CAPTAIN AND ASSISTANT SURGEON, U. S. ARMY.

THERE appeared in the issue of THE MEDICAL NEWS of November 18, 1882, an article by Dr. Stuver, of Rawlins, Wyoming Territory, relative to the efficacy of sodium bicarbonate in the local treatment of acute tonsillitis. As for several years I have been using with much benefit this remedy, combined with myrrh tincture, camphorated opium tincture, and water, as a gargle, in both private and hospital practice, I can fully corroborate his experience in this particular. There are few diseases usually so innocent in their results which are accompanied during the first thirty-six hours of their progress with the same degree of local and general discomfort as acute tonsillitis; and, unfortunately, there are few remedies which have afforded, in my experience, any substantial or permanent benefit during the time specified.

With the exception of warmth and moisture, in the form of gargle or spray, which ordinarily gives immediate though temporary relief, I know of no local treatment so beneficial as the gargle above mentioned. If acute tonsillitis is seen sufficiently early—within a few hours after the local inconvenience has been experienced, and before any marked congestion and enlargement of the tonsils, or general disturbance, as accelerated pulse, increased temperature, intense headache, and that extreme malaise incident to this affection, have occurred—it may be, and frequently is, aborted by once or twice cauterizing thoroughly the tonsils and pharynx with a silver nitrate solution, varying in strength from ten to twenty grains to the ounce of water.

Usually, however, the case is not seen thus early, in which event the silver nitrate treatment will almost invariably increase the local distress, and interfere materially with nature's reparative efforts. The proverbial, and at one time so popular, treatment of acute tonsillitis by the potassium chlorate and iron tincture, either locally or generally administered, I have given a fair trial from time to time during the past fifteen years, and I am compelled to state that the result of such treatment has been, in my experience, far from satisfactory; in chronic or subacute tonsillitis, however, these remedies I have frequently found reliable and beneficial.

The general and favorable repute of the sodium bicarbonate in the treatment of so many functional and structural diseases peculiar to mucous tissue, and the consequent assumption that acute tonsillitis had probably been included in its applications, are the reasons why my experience with it in this affection has not been before reported.

Dr. Stuver's promptness, however, in reporting his experience with it in this disease is commendable, and will, no doubt, if properly observed and acted upon, be followed with much relief to patients, and repute to the physician who will give it a fair trial.

I differ from him only in the belief that it is very

beneficial at times in solution as well as in powder, and a more extended experience will, no doubt, demonstrate this. It will be found very serviceable in many cases of the acute tonsillitis of scarlatina.

MEDICAL PROGRESS.

Fat-necrosis, a New Disease.—Prof. W. Krause describes under the title of Ponfick's disease, or necrosis of the fatty tissue, a case which appears to illustrate the condition only recently (*Virchow's Archiv*, Bd. 90, p. 520) described by Balser, Prof. Ponfick's assistant. The disease starts with a gradually increasing deposit of fat-cells in the neighborhood of the pancreas, which finally reaches such an extent that it causes the destruction, usually accompanied by extensive hemorrhage, of all the other abdominal adipose tissue, particularly that of the mesentery. In the case reported by Krause, gastric distress, vomiting, and peritoneal irritation, followed by collapse, preceded death by only two days. The autopsy showed extensive pancreatic hemorrhage, with degenerative kidney disease.—*All. Wiener med. Zeit.*, January 2, 1883.

Gelseminum Sempervirens in Tetanus.—Dr. J. Marion Sims reports the following case: Early in September, 1880, he was called to see a strong, healthy mulatto woman, twenty years old, who was suffering from well-marked tetanic convulsions, caused by a broken bit of glass, on which she had trodden two days previously, and which was embedded in her heel. He administered chloroform to enlarge the wound and search for the broken glass. It was impossible to anæsthetize her profoundly, and her foot was forcibly held by strong assistants while he made free incisions, but failed to find the fragment of glass. The wound was then filled with morphia, and a common poultice applied; and a cathartic was given, which acted promptly. Knowing well the inefficiency of chloroform, chloral, and opiates in tetanus, he determined to try the effect of the gelseminum sempervirens, because of its well-known power of relaxing all voluntary muscles. He therefore ordered twenty minims of fluid extract of gelseminum every two hours, alternating with the same quantity of liquor potassæ at the same intervals. There was great difficulty in deglutition, but milk and soups were taken in small quantities frequently. On the morning of the second day there was a slight improvement in the rigidity of the jaw, and the general spasms occurred only every three or four hours. But, as the day advanced, the jaw became more rigid, and there were violent and painful contractions of the muscles on the front and back of the chest. The general spasms also became more frequent, and sometimes occurred during sleep. The dose of gelseminum extract was then increased to forty minims every two hours. During the third day there was a marked improvement in both tonic and clonic spasms; the medicine was continued in forty-minim doses. By the close of the fourth day the rigidity of the jaws was almost entirely relieved, and the general spasms recurred at longer intervals, and with diminished violence. After this period, the improvement was rapid and regular, and the dose of gelseminum was reduced to twenty minims, at which it was continued till full convalescence. No remedy of any potency was used after the first six hours but gelseminum, and there can hardly be a doubt that the cure was the result of its use. The extract was given for a week in amounts closely approximating half an ounce to an ounce every twenty-four hours; it produced no other sensible effect than that of controlling the spasms and arresting the disease.—*Brit. Med. Journal*, December 23, 1882.

Excitation of the Human Brain.—Sciamanna (*Arch. di Psichiatria*, 1882, p. 209) had the opportunity of applying both faradic and galvanic stimuli to the brain (chiefly through the dura mater) of a man who, in consequence of an accident, had lost part of the right parietal bone.

Excitation of the middle of the ascending frontal convolution produced contraction of masseters and closure of the jaws; of the lower third of the ascending parietal, rising of the left ala nasi and corner of mouth; of posterior central fissure (between ascending parietal and inferior parietal lobe), flexion of arm and raising of eyebrow; of posterior portion of plica supramarginalis (near inferior temporal convolution), rotation of head to left, movements of orbicularis palpebrarum, of tongue, and eyebrow.—*Brain*, Jan. 1883.

The Bacillus Tuberculosis.—Balmer and Fraenzel have examined the sputa in one hundred and twenty cases of tuberculosis; in all they found the bacilli present, the abundance bearing a relation to the severity of the disease. Numerous examinations of the sputa of ordinary bronchitis failed to reveal the presence of bacilli. They believe that a prognosis can be formed upon the number and character of the organisms. Whenever they are abundant and well developed, the destruction of lung tissue is rapidly going on. When they are few in number, small, and having no trace of spores, the disease is either arrested, or is making slow progress.—*Berliner klin. Woch.*, No. 45, 1882.

Rupture of the Pulmonary Artery.—Dr. Arro reports in *Revista de Ciencias Medicas*, December 10, 1882, the case of a man who, while apparantly in perfect health, was suddenly attacked with severe pains in the chest and clavicular region, extreme anxiety and difficulty of respiration. This condition lasted for thirty hours, when death suddenly occurred. At the autopsy, the chest was found filled with an enormous quantity of blood, which had escaped from a rent in the walls of the pulmonary artery, about an inch before its division, where it was thin and dilated.—*Gaz. Méd. de Nantes*, January 9, 1883.

The First Respiratory Movement of the Newly Born.—Dr. W. Preyer, Professor of Physiology at the University of Jena, contributes to a recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* a study of the above subject. He has investigated, by means of experiments upon animals, the mode by which the first respiratory movements are brought about, and comes to the following conclusions: The necessary condition for the occurrence of the first respiratory movement is stimulation of the peripheral nerves. In utero, with the placental interchange of gases normally going on, such stimuli as the cutaneous nerves of the fœtus usually receive are not sufficient to excite the irritability of the respiratory centre. But if the amount of oxygen in the fœtal blood is diminished, the irritability of this centre is increased, and then any peripheral stimulus will excite reflex premature efforts at inspiration, which often takes place without any harm to the fœtus resulting. Without any increase in the irritability of the respiratory centre, or diminution of the amount of oxygen in the fœtal blood, extraordinary peripheral stimuli may excite inspiratory movements in the fœtus. Such movements taking place during delivery often, after separation of the fœtus, pass, without detriment to it, into normal respiration. —*Medical Times and Gazette*, December 23, 1882.

THE PATHOLOGY OF PARALYSIS IN CASES OF ARSENICAL POISONING.—DR. JASCHKE has made a careful study of two cases of arsenical poisoning which occurred in the clinic of Prof. Berger, in Breslau, and concludes, on the following grounds, that the paralysis is of peripheral origin.

1st. On account of its localization in the path of a single nerve, the median peroneal.

2d. Because the sensory disturbances, hyperæsthesia and anæsthesia, were confined to the same location.

3d. The absence of any special symptom of spinal lesion.

4th. The absence of atrophy, in spite of the prolonged duration of the disease, excluding the possibility of anterior poliomyelitis, as it is known that atrophy is much less marked in cases of peripheral lesion than when the disease is of spinal origin.

5th. Although the paralysis was strongly marked, recovery occurred, rendering the cases analogous to instances of peripheral facial paralysis.

6th. The electric reaction corresponded to that seen in peripheral palsies.

7th. The existence of pain on pressure in the affected muscles.—*L'Abeille Méd.*, January 15, 1883.

PHYSIOLOGICAL ACTION OF THE BROMIDE OF CONIUM.—PREVOST (*Arch. de Physiol.*) comes to the following conclusions from an experimental study of this drug:

1. Paralysis from the bromide of conium results from its effects upon the motor nerves, whose irritability is destroyed.

2. If the bloodvessels of the posterior extremities of a frog be tied, and then the drug injected, these parts will remain unparalyzed, while the anterior part of the body is affected.

3. In this way, the action of both strychnia and conium can be demonstrated on the same animal.

4. The vagus is affected more quickly than the other nerves, and also regains its normal condition sooner.

5. The secretion of the urine, saliva, and tears is increased by conium.

6. The conium is excreted in the urine. The urine of a cat which had been poisoned with conium was evaporated to a syrup, and portions of this were injected under the skin of several frogs, in all of which it produced characteristic symptoms of conium poisoning.

7. The secretory nerves preserve their irritability and augment the secretions simultaneously with the loss of irritability of the vagus and muscular nerves. However, electrical irritation of the cervical sympathetic and of the chorda tympani arrests the secretion of the saliva. Peripheral irritation of the nerves of the arm induces free perspiration of the palm, when muscular contraction cannot be produced. The same is true of the nerves of the foot.

8. In the warm-blooded animals, if artificial respiration be resorted to, the heart continues to beat.

9. It is doubtful if the nerve centres are at all affected by the poison, for in warm-blooded animals the convulsions were wholly due to asphyxia, and were relieved when artificial respiration was practised.

10. The irritability of the muscular substance is not affected by the drug.—*Physician and Surgeon*, January, 1883.

A NEW REACTION OF THE URINE IN INFECTIOUS DISEASES.—At a recent meeting of the Gesellschaft der Charité-Aerzte, in Berlin, EHRLICH described a new reaction of the urine. When a solution of sulphanilinic acid (*sulphanilsäure*) and ammonia is added to the urine from cases of tuberculosis, typhoid, or other infectious fever, a bright-red color is produced. The urine from cases of ordinary inflammatory or febrile diseases does not give this reaction. The details are promised.—*Berliner klin. Woch.*, January 1, 1883.

ŒSOPHAGOTOMY.—On September 4, 1882, external œsophagotomy was performed in the Kommunehospital at Copenhagen, by DR. HOLMER. The patient, a man aged thirty, was a lunatic who had swallowed a stone with suicidal intention two days before. The foreign body became impacted in the gullet a little before the larynx, and could not be dislodged either upwards or downwards. The accident was further complicated by the "cradle" of Gräfe's coin-catcher having become detached during the attempts to extract the stone, and remaining in the gullet. Dr. Holmer then made an incision along the anterior border of the sterno-mastoid muscle, and opened the œsophagus over the site of the impacted substances. The little "cradle" was first removed, and, after a good deal of trouble, the stone was seized with a pair of forceps such as are used for lithotomy in children, and extracted. The stone was found to be five centimetres long, by five centimetres wide at its broadest part. The wound was dressed with iodoform, and the patient made a rapid recovery. His voice, however, remained hoarse, owing to paralysis of the left vocal cord. This was possibly due to injury to the left recurrent nerve during the operation, but Dr. Holmer thinks it more probable that it was caused by the pressure of the stone, as the patient's voice was husky when he first came under observation.—*Med. Times and Gaz.*, Jan. 13, 1883.

THE EXTERNAL ACOUSTIC NUCLEUS AND THE RESTIFORM BODY.—MONAKOW (*Neurol. Centralb.*, No. 21, 1882) divided the left half of the spinal cord immediately below the decussation of the pyramids in a rabbit on the day of its birth. Six months afterwards the brain was examined, and the following changes found: atrophy of left lateral columns of the medulla; partial atrophy of the left formatio reticularis; atrophy of the lateral cerebellar tract; atrophy of left funiculus cuneatus and its nucleus; atrophy of the external acoustic nucleus; partial atrophy of the left corpus restiforme (inner side); partial atrophy of cortex of upper vermiform process.

No change in the auditory roots, ascending trigeminus root, or inner part of cerebellar peduncle. Hence the author concludes that the external acoustic nucleus is in relation with spinal fibres, and not with the auditory nerve nor the cerebral peduncle; that the funiculus cuneatus passes partially through the corpus restiforme; that the lateral cerebellar columns terminate in the superior vermiform process.

[In a paper recently read before the Société de Biologie, Laborde gave an account of some experiments made by M. Duval and himself on the semicircular canals and the corpus restiforme. Injury in both cases gave rise to the same phenomena (loss of equilibration). He describes certain fibres which he believes to start from the ampullæ, and some of which go to the restiforme body, others to the cerebellum.]—*Brain*, January 1883.

A MODIFIED CATHETER.—DR. HUPEDEN believes that chronic catarrh of the bladder is largely kept up by the introduction of bacteria, etc., in catheters which it is impossible to clean. He advises, therefore, that the blind end of the catheter, up to the opening in the side for the escape of urine, be made perfectly solid, so as to facilitate cleaning by removing a lodging-place for foreign materials, which is almost inaccessible for cleaning purposes.—*Berliner klin. Woch.*, January 15, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,
PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, FEBRUARY 10, 1883.

THE ANNUAL MEETING OF THE NEW YORK STATE MEDICAL SOCIETY.

IN this issue of THE MEDICAL NEWS we have the pleasure of laying before our readers a full report of the proceedings of the annual meeting of the New York State Medical Society, received by telegraph from our special reporter at Albany. The Society's proceedings this year will be read with unusual interest, on account of the importance attached to the discussion of the new Code, and we are happy, therefore, to be able promptly to place before our readers a full report of the meeting.

By a vote of 105 to 99, the Society, after a year's deliberation, has reaffirmed its approval of the "new Code," and has thereby placed itself in opposition to the expressed sentiment of two-thirds of its component county societies, of the American Medical Association, and of the entire medical community of the United States outside of a few counties of the State of New York.

The New York State Medical Society in its new Code virtually declares to the people that any one whom the laws of New York permit to practise physic or surgery, whether he be educated in medicine or not, whether he be an eclectic, homœopathist, herbalist, physio-botanist, Thomsonian, bone-setter, or what not, is in medical matters entitled to the confidence of the community, and that there exists no honorable reason why a physician should not give his endorsement to such a charlatan by meeting him in solemn consultation, and become a party to the treatment of a case in his charge, the management of which may involve the responsibility of the life or death of the patient.

The lay press, speaking for the public, will applaud the new Code, because it cannot see beyond the apparent liberality in the expressed willingness to meet in consultation any one, whatever his knowledge or fitness may be, whose services the patient can command. But it is in reality the public itself which is most injured by the Code, for it obliterates the broad distinction, which was previously easily recognized, between scientific medicine and medical charlatanry.

The new Code has been condemned with absolute unanimity by the profession outside of a few counties including the cities of New York and Brooklyn, and it remains to be seen if the large majority of county societies constituting the State Society will accept it, or if, in the event of failure to repeal it next year, they will consider it advisable to form a new State Society, and thus place themselves again in affiliation with the American Medical Association and the profession of the whole country.

THE HYGIENIC TREATMENT OF ALBUMINURIA.

IN the treatment of the different forms of renal affection included under the general term Bright's disease, albuminuria is the symptom which deserves most attention. Not because, as is commonly supposed, of the drain which such an albuminuria exerts upon the body, for even in large albuminurias the proportion of albumen is seldom more than $\frac{1}{10}$ of 1 per cent.; and even when the proportion is higher, that is, $\frac{1}{2}$ or $\frac{8}{10}$ of 1 per cent., such a loss is not very harmful, and half a pound of beef will supply the albumen lost at this rate for an entire week. The reasons why the albumen is of such importance is, rather, that it is an index of the extent of the renal disease. Without albuminuria it is not easy to diagnosticate a disease of the kidney, and especially Bright's disease, even though from time to time albumen may be absent, and we are constantly in the habit of estimating the seriousness, the progress, or decline of a renal disease by the variations in the quantity of albumen. Senator suggests that the excretion of albumen may act as an irritant to the kidney, since J. C. Lehman and Stokvis have shown that when egg albumen is introduced into the blood, more is excreted than is introduced, such increase being due to serum-albumen and globulin.

The therapeutics of albuminuria have not been satisfactory. Neither astringents, fuchsin, pilocarpin, nor the acids, have justified the claims made in their favor. The usefulness of iodide of potassium in some forms of chronic nephritis is not denied, nor our ability to combat other symptoms, as the dropsy, asthma, etc., for which we have efficient remedies, but we refer only to albuminuria.

One is easily deceived as to the usefulness of remedies for acute nephritis, since it frequently terminates favorably, independent of any therapeutic measures. In chronic nephritis, also, it is equally easy to overestimate a remedy, because variations in the course of the disease are common, and the albuminuria may diminish for days, and even weeks, whether therapeutic measures are used or not—partly because of complications, partly because harmful influences are avoided, and partly because of hygienic measures. With regard to the latter, experience has shown that while very brilliant results cannot be claimed for them alone, they are at least more satisfactory than the results which follow the use of drugs alone.

Since the publication of his monograph on "Albuminuria in Health and Disease," the name of SENATOR is perhaps better known in connection with albuminuria than that of any other writer or investigator. On this account a recent lecture by him before the Berlin Medical Society (*Berlin. klin. Wochen.*, Dec. 4, 1882), on the hygienic treatment of albuminuria, should excite unusual interest.

First in importance in this method of treatment is *diet*. Two points must be remembered in relation to this: 1st, the influence which the act of digestion itself exerts upon albuminuria; and, 2d, the influence of the different varieties of food. With regard to the former, recent observation has shown that during digestion the excretion of albumen has been increased in those in whom albuminuria is present; has returned in those from whom it has disappeared; while the digestion of a full meal has even caused a transitory albuminuria in those who are otherwise free from it. Hence the rule that, *in albuminuria it is better to take small quantities of food, at short intervals, than larger quantities at longer intervals.* Much more important is the selection of suitable articles of food. Even the older physicians noticed that certain articles of food increased albuminuria, while recent experiments have shown that not only the injection of egg albumen into the blood produces albuminuria, but even its introduction into the stomach. *The use of eggs should therefore be avoided*, at least in albuminuria of long standing. The same is true of animal flesh and cheese, which should be interdicted, not for this reason alone, but because they add to the urea, and probably also to other effete proteid substances, in the blood, and thus increase the danger of uræmia. When it is not desirable to exclude meat wholly, that should be used which is poor in albumen, as veal and young fowls, and of these the "white meat." On the other hand, vegetables may be freely used, and of these the green vegetables, salads, and fruits, are to be preferred to those more rich in albumen, as the leguminous. The propriety of using other articles of food, as, for example, the fats, which, in consequence of the restricted albuminous food would seem desirable, must be determined by the condition of digestion.

As regards drink, it has been the practice to forbid the use of alcoholic drinks, because clinical experience has shown that the intemperate use of alcohol induces renal disease; but, recently, Von Pentzold has shown, experimentally, that inflammatory renal affections may be produced in dogs by ethyl and amyl alcohol. But, while water and effervescing and alkaline drinks are more suitable, the use of alcoholic drinks need not be entirely prohibited, especially to those accustomed to their use. Whiskey, brandy, etc., should always be avoided, unless special indications, as those of collapse, demand them. Senator has usually permitted the use of red wine, rather from tradition than upon any well-determined grounds. The value assigned by some to the tannin contained in these wines is not justified, for, in the first place, tannin is useless, and in the second, its quantity in the red wines is too small to have any effect. He also considers beer more harmful than wine, notwithstanding the well-known fact that the strongest beers contain less alcohol than most wines. In one instance only—in a case of the so-called albuminuria of health—did Senator find that the use of wine increased the amount of albumen excreted, while beer did not. Finally, spices and highly seasoned food, and errors of diet of any kind, are harmful.

It is interesting to note that the milk treatment, which is the most valued of the dietetic methods, corresponds entirely with the principles just laid down. In alluding to it, Senator says, "An exclusive milk diet can seldom be maintained for any length of time, and it must not be taken too literally. If an adult, for example, takes two quarts of milk daily, he does not obtain the minimum quantity of albumen required for the maintenance of life." According to Voit, an adult person, who does nothing, and receives only the so-called "sustenance diet," requires daily 85 grammes of albumen, 30 grammes of fat, and 300 grammes of carbo-hydrates; and even for aged beneficiaries, not less than 60 to 80 grammes of albumen daily are necessary. On the other hand, the 74 grammes of fat contained in two quarts of milk is more than twice the amount required, while the proportion of carbo-hydrates, not quite 100 grammes, is far too little. The deficiency is in part made up by the fats, which can substitute the carbo-hydrates. But, in order to make up the entire deficiency, more carbo-hydrates are necessary. This is done by adding a few hundreds grammes of bread, and instead of pure milk, using milk soups, made by adding carbo-hydrates,

in the shape of flour, oatmeal, etc. Such a milk diet can be carried out with good results, and corresponds with the above-named conditions of a diet for albuminuria.

In this admirable lecture, which is based upon common sense as well as scientific reasoning, Senator refers to the treatment of albuminuria by *mineral waters* and *baths*, by *rest* and *climate*. The advantages sometimes derived from the first, he is inclined to ascribe to their action upon digestion, the saline or alkaline saline waters being those generally most useful. Hot baths are useful by favoring the action of the skin, inviting the blood to the surface, and promoting molecular change. For favoring the first two objects also, the use of woolen underclothing is efficient.

Since *muscular exertion* has been found to increase albuminuria, Senator highly approves of rest in bed, and if the patient suffers for the want of fresh air, he recommends driving. He might have added that daily massage and the sun-bath are also admirable substitutes for the muscular exercise which is forbidden. Especially should muscular exercise be avoided by women during menstruation, for it has been observed that albuminuria is increased at such times, quite independently of the admixture of menstrual blood. Psychical influences such as fright, or intense emotion of any kind, having been found to aggravate albuminuria, should be carefully guarded against.

Finally the *climatic* treatment may be made to include nearly all of the foregoing, and is therefore likely to be of the highest service. The Southern dry climates are the most beneficial. What the climatic treatment is to the rich, hospital treatment is to the poor, for in it, too, are combined the dietetic measures, the uniform warmth, and the rest in bed, which are so essential in the treatment of albuminuria.

Most, if not all, of the methods of treatment above mentioned have been tested by ourselves, and we can freely say with Senator, that while brilliant results in chronic albuminuria are as rare by hygienic as by other methods, it is still possible by means of them, not only to decidedly diminish the excretion of albumen, but also, at times, to cause its entire prevention—to produce in fact what may be termed a cure.

ANÆSTHETIC MIXTURES FOR SMALL OPERATIONS.

IT is often desirable to apply locally some anæsthetic material to deaden the sensibility sufficiently for small operations. There are various expedients proposed for this purpose. We do not now refer to the use of ether spray, but to various liquids which may be applied directly, and the sense of pain so far obtunded as to permit incisions without experiencing any other sensation than the mere touch. The mixture of chloral and camphor is often useful. When equal parts of chloral and camphor are triturated together, a clear, somewhat viscid, transparent solution results. This solution has considerable solvent power, and will take up a comparatively large proportion of morphia. Chloroform may also be added to it without precipitation of any portion of the dissolved constituents. Thus: ℞. Chloral., Camphor., āā ʒij; Morphiæ sulph., ʒss; Chloroformi, ʒj.—M. This may be applied with a camel's-hair brush over the area to be incised, allowed to dry, and reapplied as freely as may be necessary to render the part insensible to pain.

Amongst the anæsthetic mixtures for surgical purposes proposed by Prof. Redier, are solutions of camphor in ether and in chloroform. According to Redier, one drachm of camphor may be dissolved in two drachms of ether, or the same quantity of camphor in two drachms of chloroform. A useful anæsthetic mixture is prepared by the addition of crystallized acetic acid to chloroform, in the proportion of one part of the acid to twenty parts of chloroform. These anæsthetic solutions are applied by the brush freely over the part the seat of pain, or to be incised. In some instances it may be better to moisten a cloth or some cotton and allow it to remain for some time in contact with the part.

Pure carbolic acid has an anæsthetic effect when applied to the skin. This fact, originally stated by Dr. Bill, of the army, in a paper which appeared in the *American Journal of the Medical Sciences* some years ago, has been utilized to some extent since, to lessen the pain of incisions in the skin in small operative procedures.

MYXŒDEMA.

M. GUERLAIN recently presented to the Société de Chirurgie, of Paris, an eminently characteristic communication on "the influence of traumatism in the development of that curious affection which M. Charcot has described under the name *myxœdema*." All the world, outside of France, knows that Sir William Gull first mentioned this disease as a "cretinoid state supervening after adult life in women," the paper appearing in vol. vii. of the *Transactions of the Clinical Society of London*. The term "myxœdema," was proposed by Dr. William M. Ord, in a paper to be found in vol. lxi. of the *Medico-Chirurgical Transactions*. Charcot was not even the first author to write on this disease in France. Dr. Hadden, we think, gave the first account of it in *Le Progrès Médical*, Nos. 30 and 31, for 1880.

Although M. Guerlain cannot maintain the claim put forward for Charcot, he succeeds in showing

that some cases have their origin in lesions of the cervical sympathetic, and he presents the details of one example thus originating. At the same meeting M. Verneuil referred to a case communicated by Dr. Henrot, in which the cervical sympathetic had undergone hypertrophy, having attained the size of an index finger. The view which has been maintained by neurologists that myxœdema is a nervous affection, receives strong support, therefore, from these examples of the disease caused by an affection of the sympathetic.

THE APPROPRIATION TO THE LIBRARY AND MUSEUM OF THE SURGEON-GENERAL'S OFFICE.

IN our issue of last week, page 116, was a news item that "The Army Appropriation Bill, as reported to the Senate, abolishes the office of Assistant Surgeon-General, and appropriates $15,000 for the purchase of books for the Army Medical Museum." We are very sorry to learn that, so far as the appropriation is concerned, this item is incorrect. Instead of giving $15,000, the appropriation is proposed to be reduced to $5,000, for the museum and library together. It will be remembered that a similar reduction was proposed by the House committee on appropriations, but that it was restored to the usual amount, viz., $10,000, on motion of Mr. Butterworth.

What can have induced the Senate committee to recommend this exceedingly inexpedient reduction we do not know, although we are told that one of them says that "there is no use in spending Government money for books which nobody cares anything about except a few doctors." We can assure the committee that there are a good many doctors all over the country who are interested in having this library made and kept as complete as possible. It should have every medical book, pamphlet, and journal as soon as published, and to do this it ought to have an appropriation of $10,000 a year, besides what is required for the museum.

The benefits of such a library upon medical literature and medical education in this country are immense and continuous, and they extend to the patients of physicians quite as much as to physicians themselves. We must confess that it is a little discouraging to find a committee of United States Senators recommending such action as this in the face of the information which they have, or should have, as to the practical value of this museum and library, and as to its importance to the medical profession of the country. We give herewith the names of this Senate Committee, and we think they should hear from their medical acquaintances on this subject. It is to be hoped that the amendment will be stricken out, and that, at all events, the House Committee in conference will firmly refuse to accept this amendment.

Senate Committee on Appropriations: Hon. William B. Allison, of Iowa; John A. Logan, of Illinois; Henry L. Dawes, of Massachusetts; P. B. Plumb, of Kansas; Eugene Hale, of Maine; Henry G. Davis, of West Virginia; James B. Beck, of Kentucky; Matt. W. Ransom, of North Carolina; Francis M. Cockrell, of Missouri.

A SOCIETY FOR THE SUPPRESSION OF VIVISECTION.

THE public prints state that a society for the immediate suppression of vivisection, "the deadliest of all cruelties," is about to be started in this city, and doubtless in the other large cities of the country. Well-meaning but inconsiderate and ignorant zeal could scarcely go further. To protect animals from cruelty, whether of carter or doctor, is not only right, but laudable. But it cannot be too strongly or too often urged that to search by experiments upon animals for the functions of the different regions of the brain, or the exact effects of certain drugs, or for an antidote to the venom of dog or of serpent, and such like scientific and practical facts bearing on the health and the lives of the community, is not cruelty to animals any more than their slaughter for food or clothing, and far less than their slaughter for mere ornament or their maiming for sport. To "suppress" vivisection will be cruelty to man himself by condemning the race to needless suffering and to death by hindering scientific investigations, which will relieve the one and prevent the other.

Another point also is misunderstood. The opponents of vivisection give an impression to the general public that vivisection is a wide-spread and frequent evil, as if every callow student of medicine rushed into the field of experimentation upon animals. The fact is the other way. Few, very few medical men do any work in this direction. The proposition to restrict it to competent professors, etc., is useless, since it is practically so restricted at the present time. To say nothing of the time and trouble, the expense alone would restrict it to a very narrow circle. In fact, we doubt very much whether there be in the goodly city of Philadelphia, out of her 1500 doctors, six men engaged in vivisection, and they only occasionally, and not as a continuous occupation. Whether it be worth while to organize a whole society to suppress these six men is a serious question.

We trust that not only our professional but our lay readers will do all in their power to counteract the baneful influence of any such society if it be formed. Kindness to animals, when it becomes indirect cruelty to man, is simply monstrous.

M. DESNOS has found resorcin very effective in reducing the temperature of typhoid. Under its use, the heat has fallen in a short time three degrees Cent., and the decline of temperature is accompanied by profuse sweating. It has proved more manageable than carbolic acid, and it has a good effect on the diarrhœa. As it is a safe remedy, it will probably prove very valuable in the treatment of typhoid. M. Desnos has, also, essayed the use of resorcin in the treatment of rheumatism and phthisis, but he concludes that it has no special value in these diseases.

DR. DUPRÉ has lately made the relation of urea-formation to the functions of the liver the subject of a thesis. He concludes that, whilst the liver is not the only source of urea formation, it is the principal one. The formation and expulsion of urea and of uric acid are depurative acts in which the liver participates. All those circumstances which increase the normal activity of the liver also augment the quantity of urea, and *vice versâ*.

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Seventy-seventh Annual Meeting, held in Albany February 6, 7, and 8, 1883.

(*By telegraph from our Special Reporter.*)

TUESDAY, FEBRUARY 6TH.—FIRST DAY.
MORNING SESSION.

THE Society met in the Geological Hall, and was called to order by the PRESIDENT, HARVEY JEWETT, M.D., of Canandaigua.

Prayer was offered by Rev. Albert Foster, of Tabernacle Baptist Church.

THE PRESIDENT then delivered his

INAUGURAL ADDRESS.

GENTLEMEN—With pleasure and great cordiality would I greet you upon the return of this the seventy-seventh anniversary of our honored Society. We are gathered according to usage as representatives of the medical profession of the Empire State, to discuss scientific subjects connected with our profession, to strengthen our social and fraternal ties, and to animate our mutual zeal and industry in the exercise of our daily toil and philanthropic labors.

You will pardon me if, at the very threshold of my present duties, I pause to make my grateful acknowledgment for the high compliment of an unanimous election to the presidency of the largest medical society in the United States. Fully do I appreciate it, diffidently have I accepted it, while bringing to it my deepest interest and desire that all we say and do may leave an impress of value and improvement on the great interests we have in charge.

The age in which we live is especially characterized by the enthusiasm and push in every department of literature and science. Not alone have the special departments of our profession been advanced by the indefatigable labors of those who are devoting their time and talents to the prosecution of their work, but the art and science of medicine generally is advancing, until we look forward to further possibilities and higher achievements in scientific investigation and discovery. If we look back for half a century and mark the steady and progressive steps in medical practice, the dissipation of crude views and absurd practices that governed the profession in those days, and note what has been accomplished in this generation, we shall find an amazing advance on any other period in the world's history.

The result of all legislative enactments in this, and I believe in other States, for the last forty years, to regulate the practice and elevate the standard of medical education, has done little or nothing to abate quackery, or increase the interest in medical literature in this State. Whatever is done in regard to this subject must be done by the profession through their individual organizations. The profession is competent, through their representatives in the State and county societies, to establish what shall be the standard of attainments of those who are to be received into their ranks. A more complete and thorough preliminary education of young men who desire to enter upon the study of medicine is the first step in advancing the cause of medical science. A much higher standard of medical qualifications before the granting of a diploma is universally conceded and acted upon by the leading medical colleges in this country. These requirements, if carried out, will in the future tend to bring about the desired result. We have as a nation reached a stage of progress and development when our leading medical schools can carry the standard of professional education to a much higher plane than in years that are past. The graded course of instruction, as adopted in the medical department of the University of Pennsylvania, Harvard College, and the Syracuse University, especially commends itself to our consideration, and in due time no doubt will be adopted by the medical schools in this country as the most systematic and approved method of instruction.

In 1872 a law was enacted in this State, creating a State Board of Examination, whose duty it should be to certify to the qualification of candidates for the honor of graduation from our medical colleges. This law was not made obligatory, and was not received with favor by the medical schools at that time, hence it has been inoperative and useless. This law should be made compulsory and comprehensive, embracing all medical schools, under whatever name, which aspire to the dignity of conferring degrees upon their pupils. The existence of such a board of examination appointed by the Regents of the University and the Medical Society of the State, and entirely disconnected from the schools, whose certificate alone shall be a passport for graduation, would remove all imputation of partiality or favoritism from any source. This plan carried out will exempt the teachers from final responsibility, and sift out those who are disqualified to enter the ranks of the profession. "All medical schools that fail to come up to the required standard of instruction" will go down for want of patronage, and we shall see illustrated the doctrine of evolution in the "survival of the fittest."

The recommendations of my predecessor in relation to the establishment of separate hospitals in our large cities for the isolation and care of those who are suffering from contagious diseases, such as scarlet fever and diphtheria, as well as the humane supervision of factory children, are eminently philanthropic and demand considerate attention at the hands of this Society, and I trust that they will be speedily carried into practical operation.

The subject of the adulteration of food and drugs has been repeatedly considered by the members of this Society, as well as by boards of health in various

parts of the country. Notwithstanding all our vigilance this nefarious fraud is daily practised in our large cities. The State Board of New Jersey has established a board of analysts to whom this subject is referred. This Board, as well as our own State Board of Health, is making diligent effort to investigate and suppress this iniquity.

I would call your attention to a time-honored custom of this Society, of holding the evening session of the second day in the Assembly Chamber of the Capitol, to listen to the annual address of the President. There is nothing in the by-laws of this Society having special reference to the time or place where the President's address shall be delivered. Article 1st, Section 7th, says that "The annual meeting of this Society shall be held at the Capitol, or some convenient place in the city of Albany, on the first Tuesday in February in each year, and all other meetings shall be held at such time and place as may be determined by a majority of the Society convened at any legal meeting." Reasons may have existed in the early history of this Society, at the time of the adoption of this rule, that do not exist at the present time, and I would respectfully suggest that the annual address of the President be delivered in the hall where we hold our daily sessions.

I would also direct the attention of this Society to the efficient and philanthropic labors of our State and National Boards of Health. The National Board was organized by law in 1879, in response to an emphatic and vigorous appeal to Congress, on the part of the medical profession and the philanthropists of this country. The board has done much in the brief time of its existence, to stay the progress of contagious and epidemic diseases, to aid State and municipal boards in its advisory and coöperative capacity, in limiting the spread of pestilential diseases in our land, without materially interfering with the commerce of our seaboard, or traffic on our inland rivers. The labors of this board are practically suspended by the remarkable disregard of the public health, on the part of Congress, in withholding supplies to carry on their labors. I trust the Society at this time will give the subject considerate attention, and not only endorse the action and services of the National Board, but give an emphatic expression of their views in regard to withholding congressional appropriations to carry forward this eminently benevolent work.

At the annual meeting in February, 1881, this Society appointed a committee of five, from among the most distinguished medical gentlemen of the State, to consider and revise the old Code of Medical Ethics which had governed our action for nearly forty years. In conformity with the instructions given this committee, they presented their report at the annual meeting in 1882. At the same time a substitute was offered to this effect—that we abolish all restrictions relative to the practice of medicine, as superfluous and unnecessary in the presence of the unwritten or higher law, leaving all ethical questions to be settled by the gentlemanly instincts of the profession. The report of the committee, as well as the substitute, was printed and placed in the hands of every member of the Society who desired a copy, that they might examine and vote deliberately and understandingly upon the changes reported for their consideration and adoption. After a general discussion, in which all present had an opportunity to express their views, the report of the committee was adopted by a large majority. The new Code has not been received by the profession, or the medical press, in this and in other States with cordiality or favor, but on the contrary by the most outspoken and emphatic opposition. The county societies, at their first meetings, expressed their surprise at and disapproval of the new Code adopted by a majority of their representatives, as unbecoming the dignity of the profession, and as revolutionary in its nature, and "disorganizing in its tendency." A year's consideration, a calm and dispassionate discussion of the matter, has greatly modified the views of the profession in reference to the objectionable measure, and I trust a more conservative sentiment exists to-day than at the time of its adoption.

The American Medical Association, at the annua meeting at St. Paul in June, 1882, refused admission to the delegates from the Medical Society of the State of New York, because they failed to recognize some of the provisions of the old code, which had controlled their action for so many years, and had taken the liberty to substitute what was deemed a more progressive and liberal spirit in reference to established rational medicine as it exists at the present time. The objectionable clause in the new code consists in the *permission* of consultation with any *legally* qualified practitioner of medicine, as not derogatory to the interest and dignity of the profession, or in cases of emergency, or where such aid is required, upon the broad ground of common humanity.

The advocates of the new code assert that this is merely permissive, that no one is under obligation, expressed or implied, to meet an irregular practitioner in consultation, unless he prefers to do so, but in certain cases it would be illiberal, inhuman, and contrary to the spirit of the age, to withhold professional aid, because of "difference of opinion in creed or belief." The attention of the Society at this meeting is directed to a consideration of the merits of this subject, to confirm, modify, or abolish the new code, as in their wisdom and judgment they may deem most conducive to the welfare, dignity, and interests of the medical profession of the State of New York.

One subject of painful interest remains for our consideration, to which I must direct your attention before proceeding to the business before us. Death has entered our ranks during the past year and removed those who stood high in the esteem of our profession. We record the death of Prof. James R. Wood, of the city of New York. He was regarded as among the most able teachers and distinguished surgeons of this country. Dr. George Burr, of Binghamton, and I. Foster Jenkins, of Yonkers, both prominent members of this Society, as well as of the cities in which they lived, have been removed by death since our last annual gathering. The memory of these distinguished gentlemen will receive suitable consideration at the hands of this Society.

With the confident expectation that this session will be characterized by harmony in its deliberations, and made profitable to the great State we represent, I would announce that we are ready to attend to the business for which we are convened.

THE PRESIDENT then announced the appointment of the following committees.

Business Committee.—Drs. Alexander Hutchins, of Kings County; C. C. F. Gay, of Erie; and B. L. Hovey, of Rochester.

Committee on Credentials.—Drs. E. V. Stoddard, of Monroe County; L. E. Felton, of St. Lawrence County; and T. H. Squire, of Chemung County.

On motion of DR. S. O. VANDER POEL the following was adopted:

Resolved, That the subjects contained in the President's address be referred to a committee of three for consideration and appropriate action.

On motion of DR. WM. C. WEY, a recess of ten minutes was taken for registration and to enable the Business Committee to arrange for the reading of papers.

THE SECRETARY, on resuming the business of the meeting, read the list of counties in the call for communications. Communications were presented only from

the counties of Westchester, Monroe, and Broome, which were on motion received and placed on file.

REPORT OF COMMITTEE ON EXPERIMENTAL MEDICINE

was presented by Prof. John G. Curtis, of New York, as follows:

To the Secretary of the Medical Society of the State of New York.

SIR: In behalf and by order of the Committee on Experimental Medicine, I have the honor to submit the annual report of the Committee of 1883, as follows:

The bill of Mr. Henry Bergh, to prohibit the vivisection of animals, was introduced into both houses of the Legislature near the end of April, 1882. In both houses the bill was referred to the Committee on Public Health.

To the Senate the bill was never reported. To the Assembly it was reported adversely, on May 3d, and the report was agreed to. The terms by the bill were the same as those of the bills which were reported adversely by the Legislatures of 1881 and 1882. Thus, for the third time in succession, the Legislature of New York has put the stamp of its disapproval upon this injurious measure.

Since the last annual meeting of this Society, the committee has been apprised of the formation, in Great Britain, of a very important body, entitled "The Association for the Advancement of Medicine by Research," of which the objects are, in general, closely similar to those of the Committee.

In pursuance of the authority granted to it by the State Society, the Committee has elected as corresponding members, a number of the officers and members of the British Society, and has authorized the Secretary of the Committee, Dr. Dalton, to enter into general correspondence with that Society. The Committee has received very flattering replies from almost all of the gentlemen elected corresponding members, including Sir W. Jenner, President of the Royal College of Physicians of London; Sir Erasmus Wilson, President of the Royal College of Surgeons of London; Sir James Paget, Dr. Wilks, Dr. Lauder Brunton, Prof. Lister, Dr. Burdon-Sanderson, Prof. Tyndall, Prof. Huxley, and Prof. Rutherford.

Dr. Dalton's correspondence with the Society in question has further resulted in the receipt therefrom of a number of valuable documents, and in the establishment of a relation between the two bodies which cannot fail to prove a useful one.

At the last annual meeting of the State Medical Society the Treasurer was authorized to set aside, from moneys not otherwise appropriated, the sum of $100, and the Committee on Experimental Medicine was authorized to draw against this sum for the contingent expenses of the Committee, any unexpended surplus of the said sum to be returned to the general fund of the Society at the end of its current fiscal year.

I am happy to report that it has been unnecessary for the Committee to draw against this appropriation at all, and it is therefore, with the thanks of the Committee, returned intact to the general fund of the Society.

The expenses of the Committtee for the past year have been small, and the funds already in hand have more than sufficed to defray them, leaving a balance in the Committee's treasury to a fair amount.

In conclusion, the Committee would respectfully recommend the adoption of the following resolution:

Resolved, That this Society wishes hereby to declare anew, at the present annual meeting, its often-expressed conviction of the supreme importance to the art of medicine of scientific experiments upon living animals.

All of which is respectfully submitted.

(Signed) JNO. G. CURTIS,
Delegate of the College of Physicians and Surgeons, in the City of New York.

A COMMUNICATION FROM THE WESTCHESTER COUNTY SOCIETY

was received, transmitting the following resolutions, which had been adopted, in reference to the new Code.

Resolved, That this Society reaffirms its adherence to the principles of the Code of Ethics of the American Medical Association, and declares that, in its opinion, for a physician to extend professional recognition to irregular practitioners is to patronize and encourage irregular practice; and it is alike inconsistent with honesty of purpose and the pursuit of medicine as a science.

Resolved, That the Medical Society of Westchester County disapprove of the action of the New York State Society.

Resolved, That this resolution be referred to the State Medical Society at its next annual meeting.

DR. J. B. ST. JOHN ROOSA offered a resolution that this communication be referred to the Committee on By-laws, and that the County Society be censured for its action in repudiating the By-laws of the State Society. He said he considered the tone of the communication as entirely improper, coming, as it did, from a district society to this Association, and criticising its proceedings.

DR. GOVAN, of Stony Point, reminded the speaker that it would be highly inconsistent to condemn a county society for secession, since this Society itself has seceded from the American Medical Association.

DR. ROOSA denied most emphatically that the New York State Medical Society had seceded from any body. The American Medical Association is an unincorporated body, this Society being under no obligation to it, and never having subscribed to its rules. We do not consider ourselves in any way bound to obey the rules of the American Medical Association. This Rip Van Winkle body, this excursion association, was not thought of when the New York State Medical Society, incorporated in 1806, was already a scientific and important representative body of physicians.

DR. THOS. F. ROCHESTER, of Buffalo, said that the speaker was in error; this Society had bound itself to obey the rules of the American Medical Association, and had adopted its Code, and agreed to be bound by its provisions. If Dr. Roosa would turn to the proceedings of the Association, he believed that he would find that such a resolution had been passed by the New York State Medical Society.

DR. ROOSA.—And abrogated last year.

Amid a call of several members for the question, a substitute for the resolution, offered by Dr. PIFFARD, that the communication be received and placed on file, was carried.

A COMMUNICATION FROM MONROE COUNTY

was received upon the same subject.

DR. PERKINS offered the following:

Resolved, That all communications from county societies upon the subject of the Code, simply be announced and passed by the Secretary, without reading.

The point of order was raised, that the business of the hour was listening to reports from county societies, and that they could not be heard without they were read.

The motion of Dr. Perkins was lost, and the President stated that but a few more communications were to be read.

A COMMUNICATION FROM THE OSWEGO SOCIETY

was subsequently received, approving the utmost freedom in attending patients, without regard to medical belief, but condemning the seeking of consultations with other than regular physicians.

The reading of this communication gave rise to

much merriment, but it was, on motion, ordered to be received with the preceding and filed.

THE COMMITTEE ON BY-LAWS,

appointed at the last meeting, reported, through the chairman, Dr. Wey. It deprecated the general indifference exhibited by the several county societies to the duty of having their by-laws revised by the Committee, in order to render them uniform and in accordance with the laws of the State and this Association. The only response received was from Warren County. Having examined the by-laws of the Warren County Medical Society and found them in conformity with those of the State Society, the Committee moved that they be approved by this Association. The report was received and the resolution adopted.

The Committee further reported, that it believed that only seven county societies in the State were acting under rules in accordance with the by-laws of this Association, and the Committee, therefore, offered the following resolution:

Resolved, That the several county societies of this State be requested to submit, before the next meeting of this Society, their by laws to the Committee, in order to make them correspond with those of this Association, and of the Sate.

A motion to lay this upon the table was lost. The resolution was then adopted.

A communication having been referred to the same Committee, which had been sent in by the Otsego County Society, with reference to the law requiring the annual payment of dues by permanent members on penalty of losing their membership, the Committee presented a report showing the necessity of this measure in order to maintain the income of the Society. The Chairman read the text of the resolution passed in 1880, and offered the following:

Resolved, that it is not expedient to change the By-laws of this Society upon the subject referred to the Committee.

The resolution was unanimously adopted.

THE NEW CODE.

DR. E. R. SQUIBB, of Brooklyn, offered the following resolutions and moved they be made the special order of a special session of the Association, to be held this evening at 8 o'clock:

Whereas, The Special Committee on the Code of Ethics, in its report at the last annual meeting, recommended a change in one part of the Code which was more in the nature of a revolution than of a revision, and, therefore, may be more radical than was expected or desired by the constituency of this Society; and

Whereas, That report was adopted at a session wherein only fifty-two members voted in the affirmative, and thus legislated for the entire profession of the State on a subject of vital importance, in a direction which may not have been anticipated or desired by the profession at large; therefore, be it

Resolved, That all the action taken at the annual meeting of 1882, in regard to changing the Code of Ethics, be repealed, leaving the Code to stand as it was before such action was taken.

Resolved, That a new Special Committee of five be nominated by the Nominating Committee of the Society, and be appointed by the Society to review the Code of Ethics, and to report at the annual meeting of 1884 any changes in the Code that may be deemed advisable.

Resolved, That the report of this Committee be discussed at the meeting of 1884, and be then laid over for final action at the meeting of 1885.

DR. ROOSA moved that the resolution as offered be amended so as to read 7.30 instead of 8 o'clock. Adopted.

The Business Committee called attention to the rule adopted at the last meeting, restricting the time for the reading of papers to twenty minutes, and that any motion to extend this time be ruled out of order.

DR. SQUIBB offered the following:

Resolved, That the rules of the last meeting be extended to this session, with the proviso that the Business Committee be allowed, at their discretion, to extend the time by special arrangement.

This resolution permits the Business Committee, in case few papers are offered, to extend the time for all papers if time permits, and to enforce the rule if time will not permit.

The Business Committee announced that the reading of certain scientific papers was now in order.

DR. H. G. PIFFARD read a paper on the

PATHOLOGY AND TREATMENT OF ACNE.

After reviewing the views of Wilson, Tilbury Fox, Duhring, and other writers, with regard to the various local causes which have been assigned for this disease, he expressed the opinion that in the great majority of cases acne is not primarily a disease of the skin, but is dependent upon diseases of other organs; local irritations are secondary, and have little to do with causing the eruption. He summed up the principal causes to be (1) masturbation, (2) gastro-intestinal disorders, (3) amenorrhœa and uterine disease, (4) certain conditions of the blood. These several causes were discussed, and the author then considered the rational treatment by removal of the causes, and cited several cases in illustration. The termination of this paper was cut off by the expiration of the allotted time.

A paper on

PUERPERAL ECLAMPSIA, AND ITS MANAGEMENT BY INDUCTION OF PREMATURE LABOR,

was presented by Dr. W. W. POTTER, of Buffalo, read by title, and referred for publication.

DR. C. R. AGNEW, of New York, also presented a paper, entitled,

THE DANGERS OF SPECIALTIES IN MEDICINE,

which was likewise referred.

DR. SAMUEL SEXTON, of New York, read a paper on

REMOVAL OF FOREIGN BODIES FROM THE EAR.

Although foreign bodies are comparatively rare in adults, except in cases of lunatics, who sometimes fill their ears with foreign substances, probably with a view of keeping out noises, still they do occur, especially with bathers, who get sand and small shells in the ear. Sometimes a pin is used to scratch the ear, and it slips into the meatus; its point becomes embedded, and it is difficult to extract it from the swollen tissues; it cannot be pushed backward to relieve the point without endangering the membrana tympani. In children, small seeds and similar substances are often inserted in play, and may become impacted in different portions of the canal. In removing such foreign bodies, if the patient is difficult to control, etherization may be required. The head should be placed in the proper position, and the syringe used judiciously. Rupture of the membrana tympani may be caused by forcible syringing, especially when softened by disease. Improper syringing may also cause further impaction of the foreign body, The attempt at removal should not be made unless instruments are at hand for any emergency that may arise. He had been surprised by finding the large number of instruments which had been specially devised for the removal of foreign bodies from the ear; many of these are useless for the purpose, and most of them unnecessary.

He exhibited a new instrument devised by himself

for the purpose of seizing any foreign substance which can be impressed. It was in the form of a probe, ending in a ring at each extremity, which was inserted past the bean or other substance, and thus readily withdrew it. The end is a fine spoon-shaped loop, which can be easily inserted beyond the body; the handle is bent at an obtuse angle, so as to keep the hand out of the line of vision. He said that it was by no means necessary to have this in all cases; in many the ordinary probe is all that is needed. It is sometimes necessary to incise or lacerate the tissues, in order to remove a foreign body, but this should never be done unless the proper instruments are at hand to complete the extraction, as the consequent swelling only increases the difficulty of subsequent attempts at removal. Care should be taken not to force the foreign body deeper into the canal against the tympanum; not only on account of the danger of pressure upon this structure, but because instruments cannot be passed beyond the obstruction to remove it without injuring the membrane.

His rule is to always make sure that a foreign body is really present before making efforts at extraction. He had succeeded in some cases where the body was deeply embedded in the canal, in removing it with the aid of a delicate pair of forceps, which he had made, which acted like bullet forceps, seizing the impressible body with tooth-like points, upon which the body may revolve, accommodating itself to the canal in withdrawal.

DR. D. B. ST. JOHN ROOSA opened the discussion on Dr. Sexton's paper, and deprecated the idea that all cases of ear disease require special and complicated instruments. He believed that the ear instrument of Prof. Gross would be found all that is necessary in the majority of cases, and he condemned the use of forceps, stating that a syringe and warm water are better, because safer and more efficient.

In cases of obstinate impaction of a foreign body, recognizing the danger of inflammation that might be caused by it, he believed that the operation of dissecting off the auricle might aid, which was recommended some years ago. There is no trouble about it, but the canal is not as freely exposed by the operation as might be supposed, but it is a little better for the surgeons, although not much better. The difficulty in removing foreign bodies does not occur at the beginning; it is comparatively easy to remove them from the position in which they are placed by the child, but the difficulty is caused by pushing the body further in by ill-directed attempts at extraction. The difficulty experienced in some instances is well shown by the large number of instruments that have been invented for their treatment.

DR. KNAPP, of New York, endorsed the remarks just made, especially with regard to the danger of the forceps; he had abandoned their use in both diseases of the eye and ear. He had, since then, made experiments upon the cadaver, with suction forceps, for the removal of bodies impacted in the ear, and had found them excellent for the purpose of removal of impressible bodies like locust beans or cherry pits.

The usual form of forceps only force the foreign body further in, especially glass beads. For these the hook is better. He had an instrument made for him, which was a double hook, which might be used where the body gets into the tympanum; it cannot be removed with the forceps or other instruments; the syringe will sometimes succeed in bringing it out to where it can be reached with a hook. When the canal is nearly occluded by granulating tissue, and there are otorrhœa and swelling, he recommended washing out the canal with alcohol diluted or full strength, and after wiping it out to fill the canal with boracic acid; this will cure the otorrhœa and reduce the granulations.

With regard to the case of a foreign body located in the depth of the tympanic cavity, there is a danger that it may lead to inflammation and meningitis. Cases are on record in which the highest surgical skill was required to heal them. There is a case on record where the auricle was dissected off and the mastoid process chiselled so as to release a foreign body and save the patient. In cases where meningitis was threatened he should not hesitate to chisel or trephine the cranial bones to remove a foreign body.

DR. GRUENING, of New York, said that the syringe was only necessary in the great majority of cases, and he recommended the general practitioner to depend upon it in preference to any form of instrument.

DR. A. H. SMITH, of New York, referred to a suggestion by the late Dr. Smith, of New York, to pass a brush or piece of twine wet with adhesive substance, like shellac dissolved in alcohol, which dries quickly and enables the body, through adhesion, to be drawn out.

The PRESIDENT mentioned a case in his practice, in which a small hard winged bug had been in the ear of a boy, ten years of age, for from three to five months. It was covered with cerumen, and gave rise to no disturbance beyond deafness.

DR. WEBSTER insisted upon the fact that no one should attempt to remove a foreign body unless he can see it with the aid of a good head-mirror and reflected light. This is the only safe rule.

DR. MATTHEWSON said that a foreign body may remain for a long time without causing any disturbance, so that the friends of the patient need not be clamorous for immediate treatment.

DR. SEXTON, in closing the discussion, said that he would reply to some criticisms that had been made, that his paper had presupposed some knowledge of the use of the syringe by the members, and he had, therefore, simply called attention to the danger of its improper use. With regard to trephining the mastoid, he thought that it would only be necessary in case the foreign body was a bullet.

DR. W. B. CHASE read a paper on

HOT WATER AS A HÆMOSTATIC,

in which he recommended its use in surgical cases as well as obstetrical. It does not interfere with primary union; on the contrary, it rather prevents excessive inflammations. It has been useful not only in post-mortem hemorrhage, but also in bleeding attending uterine growths. He reported a case in which such a growth was attended by profuse bleeding, and the patient was in a condition of extreme collapse. The bleeding was checked by hot water, the tumor was removed, and the patient recovered ultimately. The temperature was preferred at from 105° to 130°.

DR. CORNELIUS R. AGNEW, of New York, read a

REPORT FROM THE DELEGATION TO THE AMERICAN MEDICAL ASSOCIATION.

He said that he had proceeded to St. Paul, and on the day before the meeting had attempted to register, but his credentials were not accepted, the Secretary stating that the Judicial Council had directed him not to receive any delegate from the Society of the State of New York. He then registered as a delegate from the New York County Medical Society. He called attention to the persistent efforts of a member of this Society to create professional feeling against the State Society at this meeting, and spoke of his receiving many expressions of sympathy from other members of the Association.

To the report was appended a certified copy of the letter sent by L. A. Sayre, M.D., the other delegate, declining to serve on the ground that he was not in sympathy with the action of the Society with regard to

the repudiation of the Code of Ethics, which had been read at the meeting of the Association.

DR. ROOSA, commenting upon this report, said that there was a letter in possession of a member present, charging Dr. Sayre with consulting with a homœopathic practitioner.

The letter was called for.

DR. SQUIBB said that it was unjust to read the letter in the absence of Dr. Sayre. He did not doubt the existence of such a letter; it was merely a question of veracity between its author and Dr. Sayre.

On motion, the further discussion of the subject was referred to the evening session.

AFTERNOON SESSION.

The meeting was called to order at 3 o'clock, by the President.

The COMMITTEE OF ARRANGEMENTS announced the following as

MEMBERS BY INVITATION:

Dr. S. S. Cartwright, of Roxbury; W. W. Seymour, of Troy; Hiram Wiggins, of Elbridge; H. H. Deane, of Watertown; Bunchanan Burr, of New York City; L. E. Holt, of New York City; C. W. Green, of Albany; J. W. Whitbeck, of Rochester; John E. Burdick, of Johnstown.

DR. GEO. H. FOX, of New York, read a paper upon the

TREATMENT OF CHRONIC URTICARIA.

After discussing the etiology of urticaria, which he declared to be usually dependent upon (1) some functional disorder of the digestive apparatus, and (2) an abnormal condition of the sympathetic nervous system, he said that the means for the cure of chronic urticaria, must always depend upon recognition of this fact, and the use of internal remedies, especially by removal from the intestinal tract of irritating material, and removal from the blood of the waste products of tissue metamorphosis. Among the remedies which had been found especially useful, were alkaline diuretics, saline purgatives, bicarbonate of sodium (ʒss in carbonic acid water half an hour before each meal); gelsemium also has a beneficial action. It is sometimes advisable to restrict the diet, and direct the patient to abstain from certain articles of food, which are especially irritating; and those purgatives which allay irritation, like rhubarb, are often required. When much irritation is present, bismuth has special advantages. Sulphurous acid, well diluted, will often produce a speedy effect upon the eruption; it probably acts by arresting fermentation in the alimentary tract. A case had been reported by Dr. Shoemaker, of Philadelphia, of chronic character, in which all the usual remedies had been used without avail. On recommendation of Prof. Da Costa, sulphurous acid was then given, with alkaline baths at night. The effect was almost magical, and the patient was relieved at once and cured in a few days. The lecturer had used this treatment with equal success. A lady who was apparently otherwise in perfect health, was troubled with chronic urticaria; the only evidence of gastro-intestinal derangement was a slight coating of the tongue. Many remedies had been used without relief, but upon giving this acid there was marked improvement on the second day, and a cure followed within a week.

A second class of cases are those depending upon some disorder of the nervous system due to the presence of certain substances in the blood. To this class belong the cases of urticaria caused by the administration of remedies such as quinine, cinchonidia, etc. When urticaria occurs in the course of ague, it is a question in some cases, whether it is attributable to the malarial poison or to the remedies given. Physicians should bear in mind that some patients have a special susceptibility, and a mininum dose of the cinchona salts will cause an urticarial eruption. In other cases, the eruption is symptomatic, and is cured by quinine. Cases have been recorded when the urticaria was periodical and appeared at the same hour every day. For the neurotic cases belladonna, or atropia has been used with good results; salicylate of sodium (gr. j every hour until some physiological effect has been produced) has been recommended; larger doses are more likely to cause the eruption than to allay it. Arsenic is an old remedy often used, but more calculated to relieve than to cure the disease, a fact doubted by Tilbury Fox, and denied by Hebra. The bromide of potassium is sometimes said to be curative, by Duhring. The balsam of copaiba has been recommended in drop doses as curative, but the lecturer had not found it so in his experience. Dr. Heitzman had recommended fluid extract of ergot, which had been also useful in the hands of other writers. Wine of iron, and nettle tea have been reported as producing cures.

From the foregoing, it is seen that the treatment of urticaria is generally empirical and highly unsatisfactory. The apparent value of remedies has been based upon careless observation, as they have given when the evanescent eruption was about subsiding, as it would do of itself without any remedies whatever. The successful treatment of urticaria must depend upon a knowledge of its etiology in each case; and a knowledge of this kind is more essential to its cure, than any amount of experimentation with unknown or known remedies

DR. ROCHESTER recommended in acute cases an emetic dose of ipecacuanha, to be repeated if needed; he had found it very effective. Possibly the secondary diaphoretic effect may have something to do with the result. In chronic cases after using ipecacuanha, he places his patient upon a milk diet (four-fifths of a quart a day), and only a small amount of bread, with no medicine whatever, and referred to a case in which this had proved successful.

THE COMMITTEE ON PRIZE ESSAYS

reported, through its chairman, that only one essay was submitted for examination; it was entitled "*Cancer—A Pathological Study of Cancer of the Lip.*" It was well written, and evinced knowledge of the literature of the subject, but had not contained any special original features which would render it a proper subject for a prize. The Committee expressed its regret that the author of the paper had violated the rule, inasmuch as he had announced his identity by quoting from a former prize essay as written by himself. This is the more remarkable, as an essay offered by the same gentleman was rejected at the last meeting for precisely the same reason.

The Committee requested that all future communications to it shall be written by the type-writer before being submitted in competition.

On motion, the report of the Committee was accepted, and the request embodied in a resolution, which was adopted.

The PRESIDENT appointed the following members a

COMMITTEE ON THE RECOMMENDATIONS CONTAINED IN THE PRESIDENT'S ADDRESS,

Drs. J. C. Hutchinson, of Kings; T. D. Strong, of Chatauqua; and Wm. S. Ely, of Rochester, and requested a report at this meeting.

The following names were read by the Secretary, they having been elected by the several Senatorial districts as members of the

NOMINATING COMMITTEE:

1. F. A. Castle, of New York; 2. P. R. H. Sawyer, of Westchester; 3. Maurice Perkins, of Schenectady; 4.

Conant Sawyer, of Essex; 5. J. D Spencer, of Watertown; 6. George Douglass, of Chenango; 7. H. D. Didama, of Syracuse; 8. F. F. Hoyer, of Erie, and the President appointed Dr. S. O. Vander Poel, of New York, member-at-large.

The next paper was entitled

THE PATHOLOGY AND RADICAL CURE OF HAY FEVER, OR HAY ASTHMA,

by DR. JOHN O. ROE, of Rochester.

All writers on hay fever, with a marked unanimity, agree that it is a most singular disease, that its cause is uncertain, its pathology unknown, and its treatment most unsatisfactory. This absence of definite knowledge has arisen not from lack of patient, careful, and close observation to determine its causes, but from the fact that these causes have been studied independently, that their relations to the tissue in the nasal passages, which is the part especially affected in this disease, has not been taken into consideration, and that the conditions in this tissue which render it susceptible to these influences have been entirely overlooked.

This fact is especially significant, for, in the examination of the various and more or less elaborate works on hay fever, we find no mention of any examination into the objective condition of the nasal passages nor of any investigation as to the existence of any localized diseased condition which may predispose to the affection. This is made more conspicuous when we consider the amount of labor expended by the many hard workers during the past few years, who have been carefully investigating the conditions of the tissue of the nasal cavity to discover the cause and means of cure of chronic nasal catarrh.

These investigations have revealed that the cause of nearly all of the most obstinate forms of nasal disease, which have been considered incurable, can be removed, and the diseases more or less effectually and permanently cured. They have also shown the nose to be a very important organ for maintaining, in a normal condition, all the organs with which it communicates, and have revealed relations existing between diseases of the nasal cavities and disorders of other, and sometimes distant, organs, which were before unsuspected.

As a further result of these investigations, it is clearly demonstrable that the special cause for hay fever does not alone reside in a special peculiarity of a special irritant, which affects certain individuals in a peculiar manner, but in a special susceptibility of the tissue of the nasal passages of some individuals to be irritated by these substances when brought in contact with it; that this susceptibility of this tissue is occasioned by disease, either latent or active; that the removal of this diseased tissue will remove the susceptibility to irritation by these substances; and that the train of symptoms which appear to be more or less of a constitutional nature, producing the asthmatic and nervous symptoms (which have led to the classification of the affection as a neurosis), are but the result of the irritation of the Schneiderian mucous membrane, which is reflected to other parts and organs through the agency of the sympathetic nervous system, causing irritation in these organs, which is augmented by the consequent obstruction to nasal respiration during the attack.

The importance of unobstructed nasal passages, and free nasal respiration is generally recognized, but in seeking for the cause of the symptoms which arise when these passages are obstructed, the nose is quite commonly overlooked. It is for this reason that I have purposely discussed more or less in detail this sympathetic connection which exists to a greater or less degree between the nasal cavity and other parts and organs, and have endeavored to make it clear that the train of symptoms attending this affection, as suffusion and irritation of the eyes, sneezing, asthma, and other local or systemic derangements, is the result of this intense local irritation set up in the tissue of the nasal passages by these irritating substances.

In this relationship I also wish to point out that latent, as well as active, disease of this tissue will in many instances excite in it an hyperæsthesia or an inordinate sensitiveness to local impression.

The conclusion that this hyperæsthetic tissue of the nasal passages sustains a certain relation to the causation of hay fever has been reached in a natural manner, by observing from time to time that patients who were under treatment for nasal diseases, and who also suffered severely from hay fever during the summer months, were relieved, or their attacks lessened in severity, in proportion as these diseased conditions in the nasal passages were removed. And that, in cases where this hypertrophied turbinated tissue was removed altogether, the patient became entirely exempt from subsequent attacks.

It has been observed, furthermore, that in every instance in those who were subject to hay fever, more or less disease or hypertrophy of this tissue existed, although hyperæsthesia of this tissue is not induced in but a portion of those in whom this hypertrophy is found. And, as this hypertrophy is the cause in nearly all cases of what is termed nasal catarrh, so we find that hay fever is most prevalent in those regions where there is a predisposition to catarrhal diseases, and where the atmospheric conditions are such as to cause these hypertrophies.

A number of illustrative cases were then given.

Thus, from the study of hay fever, in the light of the most recent investigations as to its cause, and our present knowledge of nasal diseases and their influence on other organs, we may draw the following conclusions:

1st. That hay fever is an affection not confined to any age, sex, or condition in life.

2d. That it is excited by the pollen of flowers or grasses, dust, or other irritating substances floating in the atmosphere, which are brought by inhalation in contact with the nasal and bronchial mucous membranes.

3d. That the nasal mucous membrane in certain individuals is very susceptible to the irritating effect of these substances, while in others it is not.

4th. That this hyperæsthesia is associated with or occasioned by a diseased condition, either latent or active, of the naso-pharyngeal mucous membrane, and with a hypertrophied condition of the vascular tissue covering the turbinated bones and the lower portion of the septum.

5th. That the systemic disturbances, such as asthma, etc., are the effect of the local irritation of this diseased tissue in the nasal passages, which is reflected to the larynx, bronchi, and lungs, through the correlating functions of the sympathetic ganglia connecting these different regions.

6th. That the treatment during the attack can only be palliative, such as to soothe the inflamed parts, and to quiet the systemic disturbance which may be occasioned.

7th. That in most cases the only effective relief during the attack consists in going to a seaport or mountainous region, or to any locality where the air is free from the substance which produces the irritation.

8th. That curative measures can only be adopted when the individual is free from the attack.

9th. That the removal and cure of the diseased tissue in the nasal passages removes the susceptibility of the individual to future attacks of hay fever.

This paper was discussed by Drs. Wey, Sabine, A. H. Smith, Green, and Pomeroy. Doubt was expressed

as to the efficiency of the measures proposed, and attention was called to the instantaneous relief experienced by some persons on change of locality. It was thought that the cause could not be a local organic one, for if it were it could not be so readily relieved without local treatment.

DR. ROE replied, that the cases referred to were from five to thirty years' standing, and had been free from disease for from one to three years after operation. He believed that the operation rendered the patients less susceptible to various irritants, which are exciting causes of the diseases.

The BUSINESS COMMITTEE read a list of papers to be presented this afternoon.

The SECRETARY read from the By-laws the provision with regard to the registration of delegates prior to voting.

The Committee of Arrangements announced the following as

MEMBERS BY INVITATION.

Drs. T. Z. Gibbs, of Fort Ann; Erskine G. Clark, of Sandy Hill; E. H. Squibb, of Brooklyn; Maurice T. Lewi and Herman Gendell, of Albany; R. C. McEwen, of Saratoga Springs; C. C. Bartholomew, of Ogdensburg; A. M. Phelps, of Chambersburg; H. S. Case, of Albany; I. N. Goff, of Cazenovia; G. D. Dunhan, of Plattsburgh; G. P. Clarke, of Syracuse; and D. F. Dayton, of Potsdam.

An obituary notice of Dr. Deville White was presented by Dr. George W. Douglass, and ordered to be published.

DR. MITTENDORF, of New York, read a paper on

A NEW METHOD OF INTRODUCING REMEDIES INTO THE EYE.

After referring to the ordinary methods of using mydriatics in solutions, ointments, gelatine disks, etc., he pointed out the objections to solutions on account of their liability to form fungoid growths at the expense of the alkaloids, of their requiring frequent renewal, and their expense, and also to the danger of administering more of the remedy than is intended to a struggling patient, part of it perhaps getting into the air-passages or the mouth. He also alluded to the fact that some persons are much more readily influenced by minute doses than others. He recommended in place of these, as more convenient and equally efficient, triturations with gum Arabic, of various alkaloids, atropine, eserine, etc. These powders admit of accurate subdivision for exact dosage, are soluble in the secretions of the eye, and are perfectly permanent and efficient. They are dusted in with a camel's-hair pencil, just as calomel is dusted into the eye. Of course, a special pencil should be used for each bottle. He had used these triturations for more than a year, with complete satisfaction. The medicament can be divided up into small powders, and entrusted to the patient without danger.

Before taking his seat he exhibited a new eye-speculum which is self-retaining.

DR. POOLEY spoke in favor of ointments for applying alkaloids, which had the advantage that they may be rubbed on the outside.

DR. ROOSA said that organisms forming in these solutions did not render them worthless, and he had not known of any case where they had proved injurious to the patient from this cause.

DR. SQUIBB said that fungi develop at the expense of the alkaloid, it is true; but they do not render the solution much weaker, even after a long time. The best plan, in his opinion, is to make solutions, for such purposes as hypodermic injections or collyria, with salicylic acid. A few grains of salicylic acid in four ounces of water make a solution in which alkaloids may be dissolved, and can be kept for years without the growth of fungi. The small amount of acid is without any physiological effect, either when dropped in upon the eye or used subcutaneously. With regard to eserine, he stated that the difficulties usually found in weighing and dispensing it on account of its deliquescent character, can be overcome by using the salicylate of eserine. This is not deliquescent, and can be readily weighed; its solutions do not form fungi. He objected to the combination of alkaloids with vaseline, as only mechanical mixtures; vaseline being a paraffine body in which alkaloids are not soluble. In place of it he suggested oleic acid, which makes a definite chemical combination with alkaloids, and is more easily absorbed by the skin.

DR. KNAPP mentioned a solution of atropine which he had which had been kept for eight years, and still was as active as ever when used as a mydriatic.

DR. GRUENING said that he had been in the habit of keeping a saturated solution of boracic acid for making solutions of atropine, homatropine, eserine, etc. He had found that it not only does not irritate, but is actually soothing to the eye. It is both antiseptic and antiphlogistic. He has kept solutions for many months without developing fungi. He did not think these organisms were injurious, but only inelegant, and solutions containing them should not be used. He had also used boracic acid solution for the astringents, such as the sulphates of copper and zinc, acetate of zinc, etc.

DR. MITTENDORFF said that he had not seen any bad results from solutions containing confervoid growths, but he would prefer not to use them. He did not recommend the abolition of ordinary solutions, but he thought that triturations will be found useful by the profession. With regard to the instance cited by Dr. Knapp, he thought it made a great difference whether the bottle was kept sealed or was opened from time to time in the patient's chamber.

The Committee of Arrangements reported the following gentlemen as

MEMBERS BY INVITATION:

Drs. Wm. Hailes, of Albany; G. S. Munson, of Albany; and John Edwards, of Greenville.

DR. INGALLS, a duly accredited delegate from the Massachusetts State Medical Society, was introduced, and expressed gratification at the honor of being present at the meeting.

A communication was received from MR. CLARK BELL, President of the Medico-Legal Society, concerning the revision of the lunacy laws, the regulation of inquests, and other subjects.

On motion, it was referred to the Committee on Legislation, with instructions to report at the present meeting.

DR. DANIEL WEBSTER read a paper entitled

SYPHILITIC DISEASE OF THE LABYRINTH.

The cases narrated in this paper occurred in the practice of Drs. Agnew, and Webster. They were interesting from the rarity with which such cases are diagnosticated during life. The principal symptoms mentioned in the books are deafness, with an ability to hear the test of the tuning-fork as usually applied. In one of the cases there was added to this autophony, the symptoms of the patient's voice sounding to himself as if he spoke into a barrel. This case after being deaf for a year gradually improved. One morning he found himself suddenly and entirely deaf in one ear, and afterwards both ears were involved. This patient was a physician 45 years of age; at 25 he had hemoptysis, and it was believed pulmonary disease existed. He recovered under the use of whiskey and out-door life. Four months before coming under treatment he had a sudden attack of tumultuous and violent action of the

heart lasting 30 hours, which was believed to be due to nervous exhaustion and professional overwork. He then became subject to neuralgic pains in the head, and subsequently became deaf in one ear. Examination revealed nothing special in his ear. He had autophony. This case was believed to be malarial, and he was put on cinchonidia and milk was added to his diet. It was afterwards learned that he had had an ulcer upon his neck three months previously. He was now put on iodide of potassium. Upon examination, ulcers were found in the throat and mucous patches in the mouth. The hearing improved under the iodide treatment; he was then seen by Dr. Bumstead. Five years later he had largely regained the hearing power of his left ear; he had been taking blue mass pills (grs. six to ten daily) almost steadily for a year without salivation. The case proved very obstinate. The second case was a druggist, 43 years of age, who contracted syphilis in the army in 1862, followed by the usual symptoms. In 1878 he had ulcers over the sternum, and six months later had an exophthalmos probably caused by orbital periostitis. He also complained of constant tinnitus in the ear, with vertigo, and loss of hearing followed. Mercurial inunctions were used, and afterward a saturated solution of potassium iodide after meals was given, the dose being gradually increased to twenty drops three times a day. When seen by the writer he had been taking this all summer, and was advised to stop the treatment. There was no external appearance of disease in the ear. On inspection the Eustachian tube was pervious. He was deaf in his left ear and was quite dizzy. Four months ago he received a blow on the right temple, and about two months later, after experiencing some tinnitus, completely lost the sense of hearing. The tuning-fork was held between the teeth and was faintly heard in the right ear. He was advised to return to the mercurial inunctions and the saturated solution of potassium iodide.

January 19, the patient's condition was improving; the click of nails could be heard at two and a half inches in the left ear. The tuning-fork was heard only in the left ear; the right ear could not be made to hear it either through aerial or bony conduction. The diagnosis was labyrinthic disease of the right ear, with chronic middle-ear disease of left ear.

The BUSINESS COMMITTEE interrupted proceedings to present DR. HENRY W. WILLIAMS, of Boston, an accredited

DELEGATE FROM THE MASSACHUSETTS STATE MEDICAL SOCIETY.

Who made some congratulatory remarks, which were responded to by the President.

DR. UPHAM, a

DELEGATE FROM THE VERMONT MEDICAL SOCIETY,

was also introduced and welcomed.

DR. R. D. POMEROY read a paper on

SYPHILITIC INFLAMMATION OF THE MIDDLE EAR, THE LABYRINTH, AND ACOUSTIC NERVE.

The principal symptoms of internal ear diseases are usually rapid and constant loss of hearing, vertigo, and tinnitus. In syphilitic cases there is also pain in the spine, running down the arms; sometimes loss of memory and optic neuritis show associated cerebral disease. There may also be facial paralysis as a not infrequent symptom, due to involvement of the nerve trunk as it enters the meatus Fallopius. This is more likely to occur than in ordinary middle-ear disease. Hemiplegia not rarely occurs. Strabismus from paralysis of the ocular muscles also may appear. As to the ear itself, ordinarily there is no discharge, but an affection of the tympanum occurs in which the membrane melts down without suppuration. These changes in the middle ear may go on to a considerable extent without giving any signs. On inspection of the meatus a little redness, or slight degree of opacity, will only be found to exist to cause suspicion of this complication. But the most likely point to give rise to suspicion of syphilitic middle-ear disease is the history of the patient. As to the pathology in the great majority of cases of syphilitic ear disease, there will be found to exist in the middle ear granulations which interfere with the movements of the chain of ossicles. In the present state of aural pathology we are not warranted in making use of the term labyrinthine disease, except in those cases in which post-mortem examination shows the disease to be limited to this locality. In making a diagnosis, the syphilitic history, the obstinacy of the case under ordinary treatment, and the efficiency of specific treatment, show the nature of the disease. In many cases the appearance of the throat will put the practitioner on the right track. The appearance of the membrane cannot be relied upon; it may be dry, opaque, or little reddened, but these symptoms do not progress with the disease. Rapid and sudden loss of hearing, autophony, false and double hearing, are also valuable symptoms.

These papers were discussed by DR. ROOSA, who said that the diagnosis between labyrinthine disease and middle-ear disease is very important to make. He observed that some deaf persons hear better in a noise, and laid down the rule, if a patient hears better in a noise he has disease of the middle-ear. If he does not hear better in a noise, whatever else he has, he has disease of the labyrinth.

DR. SEXTON denied that this point was of value in the differential diagnosis, as it is not constant.

DR. GRUENING read a paper on the

TREATMENT OF INVETERATE PANNUS BY INFUSION OF LIQUORICE BEAN (ABRUS PRECATORIUS)

and reported several cases of successful result. The fresh beans from Brazil were those used, and recommended by Dr. Wecker, of Paris.

DR. POOLEY recommended the method of treatment described.

DR. ELSBERG gave a demonstration of the

USE OF THE TONGUE SPATULA,

and exhibited his instrument first presented to the Society nineteen years ago. He claimed that the tongue should be pressed from before backward, and from below upwards—just the reverse of the ordinary practice.

DR. DAVID LITTLE reported a successful case of

OVARIOTOMY WITHOUT ANTISEPTIC TREATMENT

other than cleanliness and plenty of fresh air.

The following were announced as

MEMBERS BY INVITATION:

Drs. C. B. Herrick, of Troy; R. H. Sabin, of West Troy; W. B. Sabin, of West Troy; E. P. Tefft, of Albany; S. O. Vander Poel, Jr., of Albany; Franklin Townsend, of Albany.

Adjourned.

FIRST DAY.—EVENING SESSION.

The PRESIDENT announced that the object of this special session was the consideration of the resolution offered this morning in reference to

THE NEW CODE.

DR. SQUIBB moved that the Society go into a Committee of the Whole, for the consideration of his amendment.

The resolution, after objection by Dr. Ely Vander Warker, was carried.

The President called Dr. ALEX. HUTCHINS, of Brooklyn, to the chair. The Secretary read Dr. Squibb's resolutions.

DR. SQUIBB presented an argument in favor of their adoption.

DR. ELSBERG moved that the committee report adversely on the resolutions.

DR. ROOSA made a lengthy address opposed to changing the Code as adopted at the last meeting. He said that the opponents of the new Code used arguments worthy of the seventeenth century, and that the consent of the American Association was not necessary for the adoption of the Code. He continued as follows: "The Code will emancipate the medical profession. It is assumed that, if we continue this Code in force, we will immediately enter into brotherly relations with the homœopathists or eclectics. It is not so. We shall not ask them for assistance, but if any poor uninstructed human being wants assistance, we want the right to give it. We are not going to surrender to the homœopathists. This is not a question of drugs; it is a question of ethics. The whole American educated public has been laughing at this restricted, trade-union Code."

DR. PIFFARD replied to Dr. Squibb, denying his premises.

DR. HOPKINS read a plea in favor of the new Code.

DR. DIDAMA, of Syracuse, made a lengthy address, in which he expressed his high respect for the American Medical Association, and defended its action in refusing admission to its delegates from this Society. The repeal of the Code severed all connection with that Association. This action was taken by fifty-three men out of the three or four thousand in New York. Those in favor were influenced by a few prominent specialists, who clamored that they did not themselves wish to consult with irregulars, but they earnestly desired that others might have this privilege.

DR. ROCHESTER asked that the subject be considered from a common-sense standpoint. He denied that the abolition of the Code of the American Medical Association was demanded by humanity or progress. He said it was an advance backward. He said that the American Medical Association had been denounced on this floor as a junketing, Rip Van Winkle Association. He claimed that it contained the best men in the profession, from every State in the Union, New York included. He is a permanent member of both Associations, but would rather give up his membership in this Society than in the National.

DR. GOULEY offered the following substitute for Dr. Elsberg's motion, which the chair decided was virtually stating again the resolution of Dr. Squibb in other words.

Resolved, That when this Committee rises, it shall report to the Association in favor of repealing the new Code enacted by this Society in 1882.

DR. GOULEY appealed from the decision of the chair.

DR. VANDER POEL said that this was begging the action of the Society, as it was attempting to bind the Society by a majority vote to what really requires a two-thirds vote to be adopted.

DR. C. R. AGNEW read a carefully prepared argument, in which he claimed that in adopting the new Code the Society had merely put itself in accord with the laws of the State, which clearly recognized the existence of other classes of practitioners of medicine. "The man," he said, "whom the State has pronounced to be a legally constituted practitioner you cannot disfranchise. Repeal the new Code, and you put this Society in opposition to the policy of the State, and you attempt to coerce this Society into an attitude which no thinking man outside our profession would take."

After considerable confusion, DR. SEYMOUR, of Troy, got the floor, and made a spirited speech, after which he read a telegram received from Dr. Lewis A. Sayre, stating that he was confined to bed by sickness, and denying the charge made at the morning session.

DR. J. C. HUTCHISON, of Brooklyn, presented a memorial as follows:

"The undersigned members of the New York County Medical Society hereby express their belief that it is unwise to abandon the Code of Medical Ethics instituted by the American Medical Association in 1847. That any modification that may be advisable should be made by the body in which the Code originated, representing, as this body does, the medical profession of the United States, and that we are therefore in favor of rescinding the action respecting the Code taken by the New York State Medical Society at the annual meeting in 1882. Signed: Alonzo Clark, Austin Flint, Frank H. Hamilton, and others."

There were one hundred and two signatures, and Dr. Hutchison stated that many more could have been obtained had it been started earlier.

On motion of DR. VANDER POEL, the Committee rose and reported progress.

The PRESIDENT requested Dr. Hutchins to remain in the chair. The report of the Committee of the Whole was received and adopted.

As the hour was getting late, it was agreed to vote on Dr. Squibb's resolution without further debate. The yeas and nays were called, and the resolution was lost by a vote of 99 to 105.

DR. ROOSA then offered the following, which was, on motion of Dr. Wey, of Elmira, laid over for one year:

The Medical Society of the State of New York, in view of the apparent sentiment of the profession connected with it, hereby adopt the following declaration, to take the place of the formal Code of Ethics, which has, up to this time, been the standard of the profession of the State.

With no idea of lowering, in any manner, the standard of right and honor in the relation of physicians to the public and to each other, but, on the contrary, in the belief that a larger amount of discretion and liberty in individual action, and the abolition of detailed and specific rules, will elevate the ethics of the profession, the medical profession of the State of New York, as here represented, hereby resolve and declare, that the only ethical offences for which they claim and promise to exercise the right of discipline, are those comprehended under the commission of acts unworthy a physician and a gentleman.

Resolved, Also, that we enjoin the county societies, and other organizations in affiliation with us, that they strictly enforce the requirements of this Code.

DR. J. G. ADAMS, of New York, read the following protest:

"As a delegate from the New York Academy of Medicine, I beg leave to report my protest against the recent action of the Society of the State of New York in regard to the Code of Ethics, and I charge that the Society, by its action in this matter, has assumed an attitude and adopted a policy in direct and open hostility to the honor as well as the best interests of the medical profession.

(Signed), J. G. ADAMS."

The Association then adjourned.

WEDNESDAY, FEBRUARY 7TH.—SECOND DAY.

MORNING SESSION.

THE PRESIDENT IN THE CHAIR.—After prayer by the Rev. Irvin Magee, the minutes of the preceding sessions were read and approved.

The following gentlemen were made

MEMBERS BY INVITATION:

Drs. Thos. A. Foster, of Portland, Maine; W. L. Pierson, of Schenectady; H. M. Eddy, of Geneva; G. H. Newcomb, of Albany; C. S. Merrill, of Albany; W. H. Murray, of Albany; I. G. Johnston, of Greenfield, Saratoga Co.; A. B. Heusted, of Albany.

TREASURER'S REPORT.

DR. CHARLES H. PORTER, of Albany, presented his report as treasurer, which showed

DR.	Receipts from Dues, . . .	$2,694.53
	" " *Transactions* Sold,	607.50
	Total,	$3,302.03
CR.	Expenditures, Sundries, . . .	$1,011.56
	Printing *Transactions*, . . .	1,026.26
		$2,037.82
	Balance in Treasury, . . .	$1,264.21
	Balance to Credit of Merritt H. Cash Prize Fund, ...	$149.26

The report was referred to a committee, consisting of Drs. Perkins, Ely, and Vander Poel, who subsequently reported that they had audited the account, and found it correct.

THE COMMITTEE ON LEGISLATION.

DR. FREDERICK R. STURGIS, Chairman, reported that the bill for presentation to the legislature prepared and offered at last meeting was recommitted in order to make certain changes. A new bill is now offered in its place, providing for the formation of a Board of Examiners, with the view of throwing additional safeguards about the practice of medicine.

The second subject referred to this Committee was the recommendation of the late President, Dr. Jacobi, with regard to employment of children of tender years in factories. It reported that a bill had been prepared and would probably be reached at the present session of the Legislature.

With regard to matters referred from the Society yesterday from Mr. Clark Bell, with reference to commitments to insane hospitals, and improvement in the method of holding inquests. These matters are referred to the next Committee on Legislation, on account of want of time for their consideration.

The Committee asked the passage of the following resolution:

Resolved, That the sum of $500 be appropriated by the Medical Society of the State of New York, to be drawn upon written order of the Chairman of Committee, to meet the necessary expenses incident upon the passage of any acts affecting medical matters, which the Committee on Legislation may be instructed by the Society to attend to, and for any contingent expenses, and whatever surplus there may be shall be returned to the Treasurer of the Society.

The report was accepted.

DR. ELY VAN DE WARKER, of Syracuse, offered, as a substitute, the first recommendation of the Committee, a provision for the creation of a Board, to be appointed by the Board of Regents of the University of New York, and to contain representatives from different systems of practice of medicine, which Board shall be empowered to grant its certificate, which shall be the only authorization to practise medicine and surgery in the State of New York.

Withdrawn by Dr. Van de Warker.

DR. JACOBI denied the existence of different systems of medicine.

DR. VAN DE WARKER deplored tinkering with medical legislation, and stated that the laws enacted by advice of this Society were lamentable failures.

DR. HOPKINS, of Albany, said that the Society had never yet gone before the Legislature and asked for the protection of educated practitioners.

DR. VAN DE WARKER acknowledged that he was in error in stating that the law of 1880 was passed for the relief of the profession; it was made to protect the quack.

DR. STURGIS denied that the law of 1880 protected the quack. In seventy cases of prosecution under its provisions in New York City, there had been only three failures to convict and drive out the irregular practitioners.

DR. MANLIUS SMITH said that a misunderstanding had arisen with regard to registration. The mere fact of registration does not make a man a qualified practitioner, but, on the contrary, often furnishes the evidence whereby the person can be convicted and prevented from practising.

The report was discussed at some length, the tenor of the remarks tending to show that the registration law of 1880 was inadequate to meet the requirements of the profession, as under it quacks of all kinds could register and thereafter deem themselves legally qualified to practice.

One of the members remarked that in his county an Indian doctor, adorned with war paint and feathers, rode into the village the other day in his chariot. He registered, and was now considered a legally qualified practitioner, and placed on a footing with other members of the medical profession.

On motion of DR. WEY, the resolution of the Committee was adopted.

A communication was received from MR. CLARK BELL, offering to read a paper. Referred to the Business Committee.

DR. VANDER POEL moved the following:

Resolved, That a committee of three, consisting of Dr. S. O. Vander Poel, of New York; Dr. E. M. Moore, of Rochester; and A. Jacobi, of New York, be appointed to confer with the Board of Regents in reference to medical examinations under Chapter 746 of the Laws of 1872, and that the Committee have power, on behalf of this Society, to recommend suitable persons for examiners.

Adopted.

THE COMMITTEE ON THE PRESIDENT'S ADDRESS

reported adversely to the recommendations, and that the annual address of the President be dispensed with in future, as the subjects of importance to the Society are embodied in the inaugural address.

The report was received and placed on file, objections being raised to its adoption.

DR. A. JACOBI, on behalf of the committee appointed at last meeting with regard to the establishment of special

HOSPITALS FOR CHILDREN'S CONTAGIOUS DISEASES,

made a partial report of progress, embodying certain resolutions adopted by the New York County Medical Society recommending the appropriation by the State of funds for the erection of such special hospitals for isolation and treatment of cases of scarlet fever, measles, diphtheria, etc.

A committee was appointed and obtained a grant of land and fifty thousand dollars to start such an institution on Manhattan Island, in New York City. It will be small, containing only forty or fifty beds, but it is believed that it is only the first of a series of such hospitals, not only for the poor, but also for the rich in different parts of the city. With the establishment of

convalescent hospitals, where the cases can be isolated until danger of communication is past, then the small hospitals can be devoted to the actually sick. This new hospital is at the foot of Sixteenth Street, New York City.

Report adopted.

The following gentlemen were made

MEMBERS BY INVITATION:

Drs. H. M. Eddy, of Ontario, N. Y.; J. C. Carson, of Willard; I. De Zouche, of Gloversville; W. G. Tucker, of Albany.

THE CENSOR OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF SYRACUSE

reported attendance upon the examination, and that the graded course had proven highly satisfactory.

A paper was presented by DR. PAUL F. MUNDÉ on

THE ETIOLOGY AND TREATMENT OF CERTAIN FORMS OF NON-PUERPERAL UTERINE HEMORRHAGE.

In using the term hemorrhage, he wished to limit it to bleeding either during or between the menstrual flows.

1. It may be caused by simple erosion of the surface of the neck of the uterus. The diagnosis can only be made with the speculum. The cervix is seen to be roughened, red, and easily bleeding. He recommended exposure of the cervix with speculum, wiping it dry, and the use of nitrate of silver (ʒj to ℥j) thoroughly applied, and dry iodoform applied upon a pledget of lint. The tampon should be kept in for 24 hours, and then reapplied every day, or every other day, and be followed by injections of sulphate of zinc. Sometimes he uses caustics, or the actual cautery; pyroligneous acid, chromic acid; a surgical operation has been recommended by Emmet, consisting of paring the surface, and stitching the edges together.

2. Slight lacerations of cervix often bleed from touch; coition, or even in walking. Treatment consists in snipping off the granulations with scissors, and cauterizing the base with nitric acid. Trachellorrhaphy is required in gaping lacerations.

3. Chronic subinvolution is a very common cause of bleeding, both inter-menstrual and menstrual. He has been very successful by applying Churchill's tincture of iodine, and internally pills of strychnine, ergot, and iron. Hot-water injections are often valuable; galvanism is sometimes useful.

4. A prolonged bleeding may result from the retention of menstrual blood by a pin-hole external os, with dilated cervical canal, and secondarily from retroflexion. The treatment is by enlarging the external os by cervical incision, and trimming off the edges, making a funnel-shaped os, when the bleeding will cease.

DR. VAN DE WARKER said that he had found it very difficult to heal simple erosions by nitrate of silver, and had had good results with the actual cautery, which causes very little pain. This is not resorted to as often as it should be, although recommended by Courty, of late writers. Snipping off the surface with the scissors often exerts a powerful effect upon the erosion. He called attention to a point not mentioned—the hemorrhage attendant upon change of life, which is often really due to malignant disease of cervix.

DR. SHERMAN had found the best results from pure phenol, saturated with iodine, as recommended by Battey, of Georgia. It produces intense pain for a few seconds, but healing rapidly follows. Afterwards he uses the constant current.

REGISTRATION LISTS.

DR. F. A. CASTLE, of New York, offered the following:

Resolved, That the Committee on Publication be requested to publish in the future volumes of the *Transactions* of this Society, as an appendix, a revised list of the registrations of physicians in the offices of the County clerks of this State.

Resolved, That the sum of $150 be appropriated to cover the expense of securing the necessary information.

DR. ROBERT NEWMAN opposed the appropriation as unnecessary, it being the duty of the various county Societies to provide the information without expense, and offered to amend by striking out the second resolution.

DR. FISHER opposed burdening the *Transactions* by a mass of such material; he would rather advocate not printing the names of the county members from year to year. As to publishing such a list, he would advise a separate publication, and offered the following as a substitute.

Resolved, That such a list be prepared separate from the *Transactions*, to be revised from year to year, and that the Legislature be asked to publish the same.

DR. WEY opposed applying to the Legislature for pecuniary aid. He thought the list should be published by this Society, and the most inexpensive and ready way of obtaining this list is by including it in the *Transactions*.

DR. LEWIS said that the registry included many that are not legally qualified practitioners. The expense also would be greater than expected.

DR. DIDAMA opposed the introduction of this into the *Transactions*; he did not like to see his name in such company any more than he can help.

DR. ROOSA advocated the publication of the list.

DR. WEY moved to amend Dr. Newman's resolution by adding "and that the method of obtaining such information be referred to the Committee of Publication," which was accepted.

DR. PILCHER said that there is more in the resolution than is apparent on the surface, and seconded Dr. Fisher's amendment.

DR. FRENCH, of Montgomery, moved that the whole subject be laid upon the table. Carried.

THE NEW CODE.

DR. H. D. DIDAMA, of Syracuse, said: "Believing that the so-called new Code of Ethics is opposed to the opinions of the vast majority of the medical profession throughout the world, as expressed in the action of county, State, and National associations, and in discussions in medical journals; and believing also that this so-called code by removing wholesome restraints encourages a spirit of lawlessness and sanctions fraud, that it is hurtful, not only to the profession, but to the public, that its adoption sent a thrill of joy through the heart of every quack in the land and gave pain to the wisest and best of our associates in the regular profession; and believing that its repeal can be secured by concerted action of the friends of honesty and good order, I offer the following

AMENDMENT TO THE BY-LAWS.

Resolved, That all action taken at the annual meeting of 1882 in regard to changing the Code of Ethics be repealed, leaving the Code to stand as it was before such action was taken."

DR. WEY moved that the matter lay on the table, as the question was already covered by the resolution offered last evening.

DR. ROOSA denounced the resolution and stigmatized Dr. Didama's remarks as an insult to the majority of this Association, and hoped that the motion would be laid on the table.

DR. DIDAMA stated that he had expressed his private opinion, but he believed that he also expressed the opinion of the majority of the profession of this State, and of the Union, and of the world. He claimed his

constitutional right to present an amendment to the By-laws.

The point of order was made that no motion was before the meeting, the author of the resolution consenting to allow it to lay over until next year.

An Obituary Notice of DR. S. M. VAN ALSTYNE of Richmondville, N. Y., prepared by A. Van Derveer, of Albany, N. Y., was presented.

DR. ELSBERG presented a *Forceps-écraseur* for the removal of nasal hypertrophies.

DR. H. KNAPP read a paper entitled the

TREATMENT OF CATARACT.

He laid great stress upon quietness after the operation; we must have union by first intention, or we will have a bad result. The first condition of primary union is clean operating. His usual method of operating is section of upper segment of cornea, and iridectomy, and extraction; and he is most careful to see that no fragment of capsule or other substance is in the wound. Listerian antiseptic precautions were carried out with great accuracy in a series of cases, but no better results had been obtained than with the same precautions without antiseptic substances. Ophthalmology requires cleanliness; it requires rest after operation, the more absolute the better.

He opens the capsule at its periphery not by laceration, but by incision with special instruments. The incision heals by first intention. The results to vision are just as good as where the lens is removed with the capsule, and the percentage of success is better. His series of cases will be published in the coming issue of the *American Archives of Ophthalmology*. Here he presents simply this provisional general report of results.

DR. DIDAMA asked if he would get as good results in an antiseptic atmosphere.

DR. KNAPP did not think he would, as he required absolute cleanliness, and advised antiseptic care. The eye is usually bathed in an antiseptic fluid—the tears.

SECOND DAY—AFTERNOON SESSION.

In the absence of the President and the Vice-President, Dr. Wey was called to the chair.

DR. ROOSA read a paper on

SOME OF THE DANGERS OF THE INJUDICIOUS USE OF QUININE.

In a paper read before the American Neurological Association, in 1874, the author called attention to some possible dangers to the organ of hearing from the injudicious use of quinine. From a series of experiments upon animals, undertaken in conjunction with Dr. Hammond, he had found congestion of the internal ear and injection of the optic papilla. In some there was also evidence of retinitis. There is a special danger in those cases where hyperæmia of the eye or ear already exists. He wished to call especial attention to this danger in the treatment of pyæmia. He had with Dr. Ely treated such cases without quinine, with success. He deplored the popular use of quinine for slight reasons, as, for instance, on no other provocation than merely an aggravated cold. He was behind no one in his appreciation of quinine in proper conditions, such as an intermittent fever or neuralgia, but he wished to recall to the attention of the profession this possible danger to the organ of hearing from the ordinary doses. Pyæmia is precisely the morbid condition in which quinine should not be given, for it is essential that there be no obstruction of the emunctories, and quinine just favors this obstruction. Again in aggravated colds, it is positively harmful by increasing hyperæmia of the delicate organs of hearing. He recommended the anodyne treatment and confinement of the patient in a warm room, instead of relying upon quinine, which increases tinnitus and general distress. In malarial cases proper he believed that the morbid poison would warrant a slightly increased danger to the organ of hearing. It is true that quinine reduces temperature, but some practitioners aim particularly at reducing temperature in all cases of fever without regard to the risk to the patient of inducing sudden collapse. In conclusion, he thought that popular use of a powerful remedy can usually be traced to careless practice in the hands of physicians.

DR. POOLEY endorsed the paper, and stated that cases of septicæmia are rendered worse by quinine. The use of quinine causes amblyopia and concentric limitation of the field of vision, in all probability due to embarrassment or disorder of the circulation, and ischæmia in retinal arteries and veins.

DR. JACOBI said that in large doses quinine depresses the heart. He insisted upon a distinction between pyæmia and septicæmia; in the former there is an embolic process, in the latter a specific poison; the action of quinine in preventing the wandering blood-cells from escaping from the vessels is well established (Cohnheim), and this is what is needed in pyæmia, but it is injurious in septicæmia.

DR. MANLIUS SMITH reported the results of some experiments upon himself, in which he found that cinchonia interferes with his vision, quinine not. Cinchonia decreased the action of the kidneys, quinine not, and cinchonia produced more nervous symptoms than quinine. On one occasion cinchonia destroyed his power of taste for a time.

DR. ROOSA said that information upon this subject is largely contained in special publications, which had not yet found their way into general medical journals. He did not agree with those who had just spoken, and denied that ischæmia of the retina is a primary condition: it is secondary, the first effect is that of congestion. He could not agree with Dr. Jacobi, and he had taken issue with him upon this subject before. He could not draw any such nice distinction between pyæmia and septicæmia, and he did not believe that any such essential difference between them existed.

The Business Commit ee introduced DR. HENRY W. WILLIAMS, of Boston, who made a verbal communication upon

ORBITAL CELLULITIS RESULTING FROM ERYSIPELAS.

Until two years ago he had not seen a case, and then, within a year, saw seven cases. He first proceeded to answer the question, are there any symptoms which permit a diagnosis to be made? He thought that there are. He had seen a case in consultation, which, during convalescence from erysipelas, had several facial abscesses, the patient complained of dull pain in the eye, and protrusion of the globe. Shortly afterwards there was loss of sight. The ophthalmoscopic appearances were those of anæmia. He decided to make punctures, in order to relieve and evacuate any collection of pus. No pus was obtained. For a few days the case went on, the symptoms became more aggravated, and on the third puncture, two and a half inches in depth, a moderate amount of pus was liberated. All the objective symptoms gradually disappeared, but the patient did not fully regain sight. His second case was a child, and the pus was found at a depth of two and a quarter inches; it was evacuated fully, and the patient recovered his sight. In another case no pus was found, but it was probably prevented from forming by the punctures. Several other cases were referred to. The diagnosis depends upon the interference with vision, swelling of tissues, chemosis, and protrusion of eyeball. In cases of localized necrosis there is more local tenderness. Early evacuation is the important point

of treatment, and free discharge should be maintained in order to preserve vision. This is not a new disorder. Attention was called to it by Mackenzie and others, but he had not encountered such cases himself until last year.

DR. POOLEY reported a single primary case not dependent upon erysipelas. A single large opening had been made along the floor of the orbit, with free drainage. The loss of vision is probably due to effusion into the sheath of the nerve. These cases were described by Von Graefe and others as retro-bulbar neuritis.

DR. WILLIAMS did not agree with the explanation offered, as there was no evidence of choked disk or other change indicating infiltration of the nerve sheath. He thought it more likely that the blood supply is interfered with by exudation, resulting in pressure upon the retinal vessels before they enter the globe. He explained, in reply to a question, that if the circulation is suspended for any length of time, the vision is permanently lost just as in embolism of the central artery.

A paper by DR. DANIEL LEWIS upon the *Development of Cancer from Non-malignant Disease* was read by title.

The following gentlemen were made

MEMBERS BY INVITATION:

Drs. Louis Granger, of Tioga Co., Pa.; L. A. Tourtellot, of Utica, N. Y.; J. A. Browne, of Newport, N. Y.; Charles W. Hamlin, of Middleville, N. Y.

DR. E. D. FERGUSON, of Troy, Vice-President, took the chair.

DR. NEWMAN, of New York, read a communication upon the

USE OF GELATINE AS A VEHICLE FOR LOCAL MEDICATION,

and exhibited bougies for nasal, urethral, and vaginal medication, and rectal suppositories, made by Mitchell, of Philadelphia. These are elegant preparations, accurately divided, soluble, and flexible; exert a prolonged local action; are not affected by temperature; nor do they melt in the hand. With regard to urethral bougies, they should be introduced at night; they are first moistened with water, and then quickly introduced; after full introduction, the meatus is sealed with isinglass plaster; cotton may be placed over the meatus. They should not be applied in the acute stage of urethritis, when the urethra is so irritable that it cannot tolerate anything; and he would not recommend them in the early stage. As a rule, eight to ten bougies are sufficient to effect a cure in a case of gonorrhœa.

DR. INGALLS, of Connecticut, a visiting delegate, by invitation made some remarks upon

THE ABUSE OF QUININE.

He said that he practised some years ago along the Mississippi River, and he then observed the result of the reckless use of this valuable remedy. He thought that practitioners abuse the remedy by givig too large doses. If we can, by giving one grain every hour, get a patient under the physiological effect of a drug, we have all that can be obtained by giving larger doses. When, in giving mercury, the gums are touched, we do not continue the remedy. Why, then, he asked, should we continue to give quinine after its physiological effects are manifested. He desired also to allude to the extravagant waste of quinine. He feared that, because it was fashionable, physicians order it and do not sufficiently watch its effects.

DR. T. R. POOLEY read a paper on

RUPTURE OF THE CHOROID, WITH ILLUSTRATIVE CASES.

He referred to this as a cause of blindness which formerly had been overlooked. The globe may be injured by a blunt instrument, or by commotion, or violent oscillation, or by injury to the head. Without enumerating all the causes, he proceeded to give some illustrative cases in which rupture of the choroid occurred.

Case 1.—A German, who was struck in the eye with a stone, and was rendered unconscious; afterwards there was aberration of vision, metamorphopsia, blind for green and blue colors. A crescentic white streak at the edge of the optic disk, was seen on ophthalmoscopic examination. By this injury, the elements of the retinal mosaic are disarranged, varying curves are formed, and if the function of the sight is preserved, the patient will have metamorphopsia.

Case 2.—A medical student received a blow on the eye. Examination showed a streak as in the preceding case, but in a different situation. There was a metamorphopsia. The long vision was much greater than in Case 1; probably the optic nerve was injured in the orbit.

Case 3.—A student, struck in the eye with a brickbat. Some months after, he showed two streaks that were very narrow, and not united by transverse rupture, and to the nasal side another rupture was seen. Three distinct rents in the choroid existed. At first there was metamorphopsia and central scotoma. Then there was progressive loss of vision. Diagrams of these cases were shown. It is surprising, Dr. Pooley said, that so little disturbance was caused by the injury of such a vascular organ as the choroid, the amount of hemorrhage varying very greatly.

Cases 4 and *5* had nothing specially worthy of note, as they were not seen until a long time after the receipt of the injury.

Case 6 was a school-boy who was struck in the eye with a sling. He was knocked insensible; there was slight separation of the iris from its border; the dioptric media were clear. The retina was cloudy and vision indistinct; there was no pain. There was a hemorrhage, probably due to rupture of choroid. On the fifth day, the blood was sufficiently absorbed to reveal a rent in the upper portion of the choroid, A buckshot was removed from the orbit above the eye, where it had lain embedded since the injury. The rent was about four diameters of optic disk in length, and about three-fourths of it in breadth, running transversely into a second rent running vertically, which was larger—about six diameters in length. On the nasal side of the disk, the choroid appeared quite normal. For the present Dr. Pooley is unable to decide whether the retina is involved in the rent or not, but cicatricial tissue will form and determine this question.

DR. WILLIAMS, of Boston, being called upon, confirmed the views of Dr. Pooley. These cases are not very rare, he said; they are often caused by a blow on the front of the globe from a blunt instrument, baseball, snowball, bat, or stone, flattening the eye and producing the rupture. Generally examination is difficult from hemorrhage. Prognosis as to vision is doubtful; if the rent is near the macula, serious trouble will certainly be caused, but ultimately there may be tolerable vision. It is best not to promise too much in such a serious injury.

DR. POOLEY added, as regards the mechanism o the injury, that authorities have asserted that the rupture is caused by *contre-coup* but he insisted that his last case showed that in some cases at least the injury may be direct.

The next paper, entitled

WHEN SHOULD THE TREPHINE BE USED IN FRACTURE OF THE SKULL,

was read by DR. FREDERICK HYDE, of Courtland, N. Y.

The author considered *first*, what are the conditions demanding the operation of trephining the skull? *Second*, how soon shall the operation be performed after the receipt of the injury?

The most common causes of pressure are depressed fracture of bone, foreign substance or effusion of blood; later, there may be compression by the products of inflammation. The ordinary rule is not to trephine in simple fractures until after symptoms of compression appear. He asserted that the trephine is required in all cases where depression of bone exists, and where other means of elevation are not successful. If left alone, the case becomes complicated by inflammation of outer cranial textures: when symptoms of compression appear, it is then too late to do good by the trephine or any other means. The choice is between an early operation with a chance of success, or a late operation without relief. He did not dread access of air, nor acknowledge the great danger from converting a simple into a compound fracture. In fractures of the inner table, in punctured fractures, the trephine is generally used to remove bony spicula; why, then, should it not be used in the cases of simple fracture, when a portion of the inner table is pressing upon the brain?

DR. SQUIRE, of Elmira, then read two papers—

SOME POINTS IN RESPECT TO OVARIOTOMY,

and

ON THE REMOVAL OF STONE FROM THE URINARY BLADDER.

With regard to ovariotomy, he recommended the use of a trocar with inner and outer tube, allowing a current reverse directions. In some cases the inner tube can be dispensed with advantageously. As to time of operation, he said that the time is coming when the ovarian tumor must be detached as soon as possible, and removed early, after some preparatory treatment.

Some years ago, a young girl, seventeen years of age, was brought under his care, with symptoms of vesical calculus. Etherization and dilatation of the urethra enabled a stone to be reached and turned, and he discovered also another foreign body above it, under the pubis. Gradual dilatation enabled the stone to be removed through the urethra. Then the finger was introduced, and a depending body, like a string encrusted with salts, was found. A forceps was then introduced, but the foreign body could not be removed, and remains encysted. It was suggested that it might be a safety pin embedded in the bladder.

DR. L. E. FELTON, of Potsdam, then read a paper advocating,

THE USE OF LACTIC ACID IN DIABETES MELLITUS.

He reported the case of a young man, aged twenty-two years, who was passing three gallons of urine, containing large quantities of sugar, sp. grav. 1040. Strictly meat diet was ordered; lactic acid (one drachm and a half daily) and five pounds of flesh daily. The patient was kept under treatment for four months, and recovered entirely, the diet being gradually extended.

Several other cases were appended in which good effects were likewise observed under the use of lactic acid and a strictly sour-milk and meat diet. The cases were all under thirty years of age, and were free from the disease, except when taking food containing sugar. Skimmed milk or sweet milk caused return of glycosuria.

DR. WEY referred to a case of a man, 200 pounds in weight, who was passing 8 gallons of saccharine urine; under the use of ergot, as recommended by Prof. Da Costa, he entirely recovered and remained well, except when errors in diet were committed.

DR. FRENCH thought that the results are more to be attributed to the diet than the treatment.

DR. JACOBI also said that regulation of the diet is the principal thing, and he thinks the treatment of diabetes is more successful than it was 30 years ago. He has many patients doing well, who have had diabetes. Transitory diabetes may occur as an evidence of general ill-nutrition. It may be connected with gout, and may alternate with attacks of gout. In transitory diabetics, symptoms have passed entirely away within ten days, simply under use of iodoform, and slight regulation of diet. He thinks transient diabetes is more common than is usually believed, and would be more frequently detected if we were in the habit of examining regularly for sugar as we are for albumen.

DR. W. GILLIS, of Fort Covington, reported a case of

PUNCTURED WOUND OF THE SKULL THROUGH THE ORBIT, BY THE TINE OF A HAY-FORK, IN A CHILD.

The tine passed to the depth of nearly four inches into the left orbit. There was facial paralysis, lasting for some months, but afterwards all symptoms disappeared, except that it was impossible to teach him to talk.

DR. HOPKINS reported a case of a woman, 70 years of age, with

RIGHT HEMIPLEGIA AND ABSOLUTE APHASIA.

Intelligence preserved. Afterwards second attack of apoplexy occurred, and the patient died. No autopsy.

DR. HYDE referred to a case under his observation in which there was extensive laceration and loss of cerebral tissue. Boy recovered every sense, physical and mental, except that he could not speak; in six months he could articulate well, and two months later he could speak perfectly. The injury was on the left side; a great part of the frontal and parietal bones were carried away in the original injury.

DR. ELY reported a case of simple aphasia without paralysis in an adult woman, which has now existed for three years.

SECOND DAY—EVENING SESSION.

The PRESIDENT, DR. HARVEY JEWETT delivered

THE ANNIVERSARY ADDRESS.

[See page 149.]

Subsequently the Society sat down to its annual banquet at the Delavan House.

THURSDAY, FEBRUARY 8TH—THIRD DAY. FINAL SESSION.

The President in the Chair.

The concluding session was opened at 9 o'clock with prayer. The reading of the minutes was by vote dispensed with.

DR. WM. MANLIUS SMITH, on behalf of the Committee of Publication, explained that the delay in publishing the volume of *Transactions* was due to the members not returning promptly the proofs sent to them for correction.

DR. L. D. BULKLEY, of New York, read by title a paper on *The Management of some Forms of Eczema.*

DR. HOWE, of New York, offered an

AMENDMENT TO THE BY-LAWS,

which was laid over for one year, "That the Code of Ethics of the American Medical Association be substituted for the Code adopted by this Society in 1882." He said that then, when our State Society had gained an unquestionable right to representation, that our delegates should be instructed to advocate such modification of the National Code as shall be in accordance

with a spirit of greater liberality, or even, if advisable. to urge its entire abolition.

MISCELLANEOUS BUSINESS.

Dr. Porter moved that the Commissioners of the Capitol be requested to set aside a room in the Capitol for the future meetings of the State Society. Adopted.

Drs. Porter, Bailey, and Mosher were appointed the committee.

Dr. Porter moved that the Publication Committee be authorized to republish the early volumes of the *Transactions* which are now out of print. Adopted.

The following

REPORT OF THE NOMINATING COMMITTEE

was received and adopted.

President.—Alexander Hutchins, M.D., of Brooklyn.

Vice-President.—H. G. P. Spencer, M.D., of Watertown, Jefferson County.

Secretary.—Wm. Manlius Smith, M.D., of Syracuse.

Treasurer.—Charles H. Porter, M.D., of Albany.

Censors. Southern District.—Drs. J. W. S. Gouley, Austin Flint, and F. A. Castle, all of New York. *Eastern District*—Drs. C. E. Nichols, M. H. Burton, and W. S. Cooper, all of Troy. *Middle District*—Drs. Alonzo Churchill, S. G. Wollcott, and J. K. Chamberlayne, all of Utica. *Western District*—Drs. C. C. Wyckoff, Thomas F. Rochester, and F. F. Hoyer, all of Buffalo.

Committee of Arrangements.—Drs. S. B. Ward, of Albany; J. S. Mosher, of Albany; and Wm. S. Ely, of Rochester.

Committee on Medical Ethics.—Drs. C. R. Agnew, of New York; E. M. Moore, of Rochester; and S. O. Vander Poel, of Albany.

Honorary Members.—T. J. Turner, M.D., U. S. N., William Goodell, M.D., of Philadelphia; and Lockhart Robinson, of Edinburgh.

Delegates to State Medical Societies. Massachusetts—George L. Smith, of Rondout; E. N. Brush, of Utica; P. V. S. Pruyn, of Kinderhook; George G. Hopkins, of Brooklyn. *New Hampshire*—W. M. Chamberlain, of New York. *New Jersey*—J. C. Hutchison, of Brooklyn; Robert Newman, of New York. *Ohio*—Thomas R. Pooley, of New York. *Pennsylvania*—H. C. May, of Corning; Sol Van Etten, of Port Jervis; T. D. Strong, of Westfield. *Vermont*—E. D. Lyon, of Plattsburgh; A. J. Long, of Whitehall; C. C. F. Gay, of Buffalo. *Connecticut*—Conrad Sawyer, of Au Sable Forks; E. V. Stoddard, of Rochester; George Douglass, of Oxford. *Canada*—B. F. Sherman, of Ogdensburgh; H. G. P. Spencer, of Watertown; L. E. Felton, of Potsdam; J. C. Hutchison, of Brooklyn; and R. J. Robb.

The Committee declared it inexpedient to send delegates to the American Medical Association.

A vote of thanks was tendered to the President, Dr. Jewett, who returned his grateful acknowledgements, and then declared the meeting adjourned to the first Tuesday in February, 1884.

The meeting is said to have been the largest ever held, two hundred and fifteen members and delegates having registered.

NEWS ITEMS.

BOSTON.

(*From our Special Correspondent.*)

Reception to Drs. Holmes and Bigelow.—Following the resignation of Drs. O. W. Holmes and Henry J. Bigelow from their respective chairs in the Harvard Medical School, and their appointment as Emeritus Professors, these gentlemen were given a reception by Dr. Charles B. Porter, Assistant Professor in Surgery. Some two hundred medical men were present, among them Dr. Packard, of Philadelphia. Dr. Holmes attended on Saturday evening, Feb. 3d, a reception given in his honor at the St. Botolph Club. The report that he will soon visit England is without foundation. Readers of the *Atlantic Monthly* gladly welcome the reappearance of the Professor in an "after breakfast talk," the outcome of the "lead-poisoning" (typical wit) of which he claims to have been made a victim in early youth.

BROOKLYN.

(*From our Special Correspondent.*)

Kings County Medical Society.—A special meeting was held on Thursday, February 1st, to rediscuss the question of instructing delegates to vote against the "new" Code. After an animated discussion a vote was taken by ballot, 100 votes being cast, of which 41 were in favor of instructing them and 59 against it. The delegates are therefore left free to vote as they please.

The Pathological Society has recently elected its officers for the coming year, as follows:

President.—J. N. Freeman.
Vice-President.—J. Merritt.
Secretary.—E. H. Bartley.
Treasurer.—A. R. Matheson.
Curator.—J. H. Hunt.
Editor.—B. F. Westbrook.

PARIS.

(*From our Special Correspondent.*)

The Wound and Disease of M. Gambetta.—The clinical history of the fatal illness of M. Gambetta has just been published with fulness of detail in the current number of the *Gazette Hebdomadaire*. Prof. Lannelongue with Dr. Siredey attended the case from the time of reception of the wound up to his death: the autopsy was made by Prof. Cornil, the report being approved by Profs. Charcot, Verneuil, Trélat, and Brouardel.

The details of the accident by which M. Gambetta was wounded in the arm on November 27th, are already familiar to medical readers. The fable circulated as to the reception of the wound may be positively denied; the following account, taken from *La Republique Française* for December 2d, may be relied upon as true. M. Gambetta wounded himself: he was holding in his left hand a revolver in which there still remained an unexploded cartridge, only partially inserted within the cylinder. In attempting to adjust it, his right hand being over the muzzle of the pistol, the cartridge exploded and M. Gambetta received the ball in the palm of his right hand, just inside of the root of the thumb, it passed up the forearm and emerged five centimetres below the styloid process of the ulna. The sensibility of the hand remained unimpaired, with the exception of the palmar surface of the little finger and the internal half of the ring finger, where it was completely abolished; on the dorsal surface of these regions sensibility was diminished. The following diagnosis was made: Opening of the sheath of the flexor tendons, with injury of the tendons of the deep and superficial flexors, incomplete division of the ulnar nerve; injury of the ulnar artery and superficial palmar arch; the anterior cubital muscles were penetrated from within outwards.

With the hope of obtaining immediate union without suppuration, Prof. Lannelongue directed that the hand be kept absolutely immovable in the normal degree of extension, and applied carbolized dressings (Lister) with the hope of preventing infection.

On December 1st the wound in the hand had nearly closed, and the condition appeared very satisfactory, though the swelling between the thumb and index finger persisted, and the attending surgeon expected a rapid cure without suppuration or any complication. By December 10th both wounds had cicatrized, and although the wounded member appeared to be doing excellently, the constipation, from which M. Gambetta had suffered, became very annoying, causing, apparently, distention of the abdomen, with vague pain on pressure in the lumbar region, and gastric distress. These symptoms were, however, relieved by a copious enema, and M. Charcot, who then examined the patient, could find nothing abnormal in the abdomen. On the 15th the wounds were completely healed, and M. Gambetta was able to drive out. The abdominal distress, however, continued, and on December 17th a localized painful swelling was detected in the right iliac fossa, and the temperature became elevated, suggesting typhlitis. On the following day and night the patient had several severe chills, followed by fever, sweating, and vomiting. The symptoms of perityphlitis extending up the colon were then established, with the formation of diffused suppuration in the cellular tissue around the large intestine, but without any distinct collection of pus; therefore no surgical interference was indicated.

On December 29th there was marked erysipelas of the entire right half of the abdomen and trunk; the inguinal glands were swollen and painful. On December 31st the patient was very feeble and slightly delirious; the skin of the face reddened; the weakness and other alarming symptoms continued to increase and death occurred in the evening of December 31st.

The autopsy showed that the wound in the arm had completely united throughout its entire extent, with no trace of suppuration, and the diagnosis of the injury was confirmed. There was no solution of continuity, either old or recent, in the abdominal walls, so showing the rumor of a bullet wound of this region to have been unfounded. The brain weighed 1160 grammes (nearly 42 oz.), and was normal; it was sent to M. Duval, the President of the Société d'Anthropologie, where it will be preserved with that of Broca. The heart was normal and weighed 400 grammes; there was a small atheromatous patch at the origin of the aorta; lungs normal without adhesions. Our readers have already been made familiar with the morbid appearances in the abdominal cavity, which confirmed the ante-mortem diagnosis.

The results of this examination show that the wound of M. Gambetta appeared to have no influence on the disease which caused his death. It is otherwise, however, as regards the constipation from which M. Gambetta suffered from November 27, to December 2, which was probably dependent upon a contraction of the intestine due to old adhesions in the right hypochondrium, indicating a previous inflammation in this locality; his general health, moreover, had for more than a year been far from satisfactory, and it is possible that the inflammation caused by the perforation of the vermiform appendix might not have resulted fatally in a more healthy subject. It is probable that the diabetes and albuminuria from which M. Gambetta suffered were largely instrumental in leading to the diffuse inflammation around the colon. During the course of his last illness, however, albumen was only present in the urine after the appearance of the abdominal symptoms; while sugar was only detected once. The surgical indications never called for any operation, and even if they had been present, the general bad state of health would probably have proved an incontestable counter-indication. As one of the surgeons expressed it, a surgical operation would have been an autopsy on a living man.

THE LEGAL FRUITS OF THE NEW CODE.—During the discussion in the meeting of the State Medical Society, of New York, on the Code of Ethics, Senator Pitts introduced a bill in the New York State Senate, providing that the State and county medical societies, the State homœopathic, the State eclectic and their several county organizations, shall not adopt any rule or regulation, which shall prevent members of such societies or organizations from consulting with any duly authorized practitioner of medicine of any school in the State, and that all rules or regulations prohibiting such consultation shall be null and void. The bill, it is reported, would have been passed the day of presentation, but for the objections of Mr. F. Lansing, who objected to its immediate consideration.

NEW YORK ACADEMY OF MEDICINE.—At the meeting of the Academy of Medicine of New York, held February 1, 1883, Dr. Fordyce Barker, recently reëlected president, delivered his inaugural address. Subsequently a reception was tendered by the President and Vice-President to the Fellows to meet Mr. Seymour Haden. Dr. Barker then introduced Mr. Haden as the guest of the evening. Mr. Haden thanked the Society for the unexpected honor that their invitation conferred upon him, and explained briefly the reasons which had led him to devote his energies to art as well as to surgery. A dissecting wound, received in his youth, had prevented him from pursuing his medical work for two years. He spent that time in Italy and studied art most industriously. After regaining his health and beginning the practice of medicine, he continued to practise art, believing that the training thus given to his eye and hand was of great value to him in surgical work. He also worked in art to encourage independence in the medical profession, and to oppose the idea, prevalent in England, that a medical practitioner should be a man of only one idea.

ATTENDANCE AT THE BALTIMORE SCHOOLS.—The following statement is based on official information: The College of Physicians and Surgeons of Baltimore has 318 matriculates; the University of Maryland has 205 matriculates in the Medical Departments, 63 in the Dental; the Baltimore Medical (Paca Street) has *about* 50; the Woman's Medical College has 18; the Maryland College of Pharmacy has 87 (49 Juniors and 38 Seniors); the Baltimore College of Dental Surgery has about 40, making about 590 medical students, about 103 dental students, and 87 students of pharmacy. Total engaged in the study of medicine and its cognate branches, 780.—*Maryland Med. Journal*, January 15, 1883.

THE RIGHT OF GUESTS IN HOTELS IN CASE OF SICKNESS.—The proprietor of the Hotel Bellevue, near Seabright, N. J., who, last summer, under threat of expulsion at two o'clock in the morning, extorted $5,000 from two of his boarders who were attacked with typhoid fever, which was believed to have been contracted in the hotel through criminal negligence on the part of the proprietor, has been indicted for extortion and is now undergoing trial. The defence is attempting to prove that the patients brought the disease to the hotel with them; that Dr. Henry told Mr. Corey that they could be moved; that Mr. Corey fixed up a comfortable and airy hospital in the ball-room to accommodate them, not wishing to keep them in that part of the house where most of the people were; and that the fee of $5,000 demanded and accepted by Mr. Corey was not exorbitant.

A SHOWER OF MANNA.—DR. PEYRE PORCHER has sent us specimens of a seed which fell in showers on November 25th, over a space of several square miles in the neighborhood of Stateburg, Sumter, Co., South Carolina. PROF. JOSEPH LEIDY, who examined the specimens, reports that they are the abortive seeds of the "Sweet Gum, or Liquid Amber, Styraciflua."

AN EPIDEMIC OF DIPHTHERIA FROM INFECTED MILK.—DR. MORELL MACKENZIE writes, in the *British Medical Journal* for January 20, 1883, in regard to a severe but limited epidemic of diphtheria now raging at Hendon, which has been traced by himself and Dr. Cameron to the infection of the milk supply. Although in some previous epidemics a strong suspicion has been entertained that milk was the vehicle of the poison, the inquiries have generally been made so long after the occurrence that it has been difficult to arrive at any certain result. In this instance, however, the facts appear to be conclusive. Fifteen persons were attacked on a single day, the disease in every case being a typical example of what French writers call *diphthérite d'emblée*. All the patients received their milk from the same vendor, and no other case occurred among the comparatively large population supplied by other dairymen. It has been discovered that the purveyor of the tainted milk washed his cans in water derived from a brook which contains a large amount of sewage matter. Indeed, up to the present time the whole of the Church End district of Hendon is drained by an open ditch into the Brent, and this ditch passes slightly above and in close proximity to the brook used by the dairyman in question. In the Tenterden Park district every household made use of the tainted milk except two. One of these families had cows of their own, and the other had thrown away the milk supplied to them the day before the outbreak began, because it was thought "it looked bad." These two were the only houses in the Tenterden Park district which altogether escaped infection.

NEPHRECTOMY.—The patient exhibited at the International Medical Congress at London, on whom MR. MORRANT BAKER performed partial nephrectomy, has since had the entire kidney removed. The patient was a lad, aged sixteen, upon whom Mr. Baker had performed nephrectomy, that is to say, had incised the pelvis of the kidney, through the loin; the operation, which gave exit to about thirty ounces of purulent fluid, was followed by a very great improvement in the patient's condition. This, however, was not maintained, and after some fluctuations in the symptoms, Mr. Morrant Baker found it necessary, on the 28th ultimo, to remove the whole kidney; this it was only possible to do piecemeal. The patient who was in a most anæmic and exhausted condition, rallied from the operation very well, and has since steadily improved; the urine became free from pus immediately after the operation, and the only symptom which at any time gave rise to any anxiety was an irregular pyrexia. On inquiry at the hospital on the 18th instant, three weeks after the operation, we learnt that the patient was then in a most satisfactory state, and that there was an excellent prospect of his eventual complete recovery.—*British Medical Journal*, January 20, 1883.

PROF. HELMHOLTZ, of Berlin, has received a patent of nobility from the Emperor of Germany.

M. TOUSSAINT, Professor in the School of Medicine at Toulouse, has just been created *Chevalier* of the Legion of Honor, in recognition of his important studies on virulent diseases.

DR. BUNSEN, the eminent German chemist, has been elected a Foreign Associate of the Paris Academy of Sciences. This dignity is one of the highest in the scientific world, and is limited to eight names. Dr. Bunsen succeeds the late Prof. Wöhler.

HEALTH IN MICHIGAN.—Reports to the State Board of Health show that, with the extreme low temperature and the considerable increase in ozone, there was a marked increase in area of prevalence of erysipelas, influenza, and pneumonia. Neuralgia, tonsillitis, diphtheria, and bronchitis have also increased in area of prevalence. There was no marked decrease in any disease reported. The correspondent at East Talvas reports the prevalence of a disease in his locality that first attacks the tonsils, then the pharynx, larynx, and trachea, and sometimes the œsophagus, with enlargement of the glands of the neck, and suppuration in the ears. The health officer of the township of Crockery, Ottawa Co., reports the prevalence of sickness beginning with chills, followed by fever lasting from one to four days, with inflammation of the tonsils and throat. He also reports "many cases of winter cholera," which comes on very suddenly and is severe.

Including reports by regular observers and by others, diphtheria was reported present during the week ending January 27th, and since, at 25 places, scarlet fever at 19 places, and measles at 9 places. Smallpox was reported at St. Joseph, Berrien Co., January 27th.

NOTES AND QUERIES.

"BRITISH PIRACY."

WE have received a letter from the Editor of *The Edinburgh Medical and Surgical Journal*, informing us that the review on Baginski's paper on the "Functions of the Semicircular Canals," taken from THE MEDICAL NEWS, and referred to in our issue of December 30th, was inserted in his Review columns by mistake, having been intended by the gentleman who forwarded it for the "Periscope on Otology." We take great pleasure in entirely exonerating the Editor of *The Edinburgh Medical Journal* from any intention of wrong-doing in this matter.

CORRIGENDUM.

IN our issue of January 27th, in the note concerning the presentation of John Hunter's portrait to the New York Academy of Medicine, the donor's name should have been printed Dr. Charles Milne, and the artist's name Sharp.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 29 TO FEBRUARY 5, 1883.

DE LOFFIE, AUGUSTUS A., *Captain and Assistant Surgeon.*—Will be relieved from duty in the Department of the Missouri, and report in person to the Commanding General, Department of the East, for assignment to duty.—*Par. 3, S. O. 26, A. G. O., Jan. 31, 1883.*

ELBREY, FREDERICK W., *Captain and Assistant Surgeon.*—The leave of absence on surgeon's certificate of disability granted July 21, 1882, is extended six months.—*Par. 5, S. O. 26, A. G. O., January 31, 1883.*

KILBOURNE, HENRY S., *Captain and Assistant Surgeon.*—The leave of absence granted December 21, 1882, Department of Dakota, is extended two months.—*Par. 3, S. O. 24, A. G. O., Jan. 29, 1883.*

PAULDING, H. O., *Captain and Assistant Surgeon.*—Granted leave of absence for one month to take effect on or about the 1st of February, proximo.—*Par. 1, S. O. 11, Department of the Platte, January 27, 1883.*

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

CHRONIC DISEASE OF THE ANKLE-JOINT.

A Clinical Lecture delivered at the Bellevue Hospital, New York.

BY LEWIS A. SAYRE, M.D.,

SURGEON TO THE HOSPITAL, AND PROFESSOR OF ORTHOPÆDIC SURGERY AND OF CLINICAL SURGERY IN BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

(Specially reported for THE MEDICAL NEWS by EDWARD DEVELIN.)

GENTLEMEN: To-day I would specially call your attention to disease of the ankle-joint.

A few days ago a gentleman brought this little boy to me suffering from this disease; I requested him to bring him here to-day, in order that I may show you the means of relief by instrumental aid. On the following day another case was brought to me, the disease in this instance being in a much more advanced stage; this case I will present to you also.

Disease of the ankle is one of the most serious forms of joint disease, arising frequently from very slight causes, so slight that the disease does not develop sufficient importance to attract particular attention, until many weeks, and in some cases months, have elapsed; by this time the disease is fully developed and has caused serious constitutional disturbance; the medical man then being called in is apt to consider the disease at the joint caused by some strumous disease. This mistake has been made both at home and abroad in relation to chronic disease of the ankle-joint. They are made chronic simply because they have such a slight origin, and in course of time if allowed to run on destroy the joint and sometimes the life of the patient.

CASE I.—This child first sustained its injury by the foot slipping from the rung of a chair, the foot by some means being caught and the ankle twisted. Now observe what takes place here; the base of the tibia rests upon the astragalus and on either side are the internal and external malleoli, so that the ankle-joint is a perfect ginglymoid joint, there being no lateral motion; now between the base of the tibia and the astragalus is a thick cartilage for the purpose of receiving concussion; there is exactly the same on either side between the astragalus and malleoli, but here the cartilage is not so thick, as there is no necessity for it; around these bones passes the synovial membrane. Now when the foot is twisted to the side, the pressure may be so severe upon the thinner portion of the encrusting cartilage as to produce an extravasation of blood, and hence the nidus of this disease. There may be no swelling or heat at the joint take place at the time, and apparently there is nothing in particular that would call for attention, but in about two or three days the joint becomes a little stiff and in the course of a week or more there is a low grade of inflammation set up, an effusion is then poured out into all the little sulci of the joint, and you have a shapeless, boggy, fluctuating tumor. If then you take the foot and attempt to flex it, the child will scream with the pain caused by this action; the gastrocnemius having its attachment upon the os calcis, then draws the heel up and gives us the deformity known as talipes equinus. Now as I take the foot and make extension in the line of the deformity, you observe the expression of relief that is shown in the countenance of this child, and by continuing this extension I am enabled to make slight motion within the joint without causing pain. Now how will you form your diagnosis? You want to know whether the disease is in the joint or whether it is in the ligaments exterior to the joint. If it has been wrenched, pulled, or strained in such a manner that the ligaments have been severely stretched or partially torn, then the disease will commence in the ligaments. If, on the contrary, concussion has been the cause of the trouble, then the disease will have commenced in the interior of the joint.

Now, if the disease be in the joint, pressure of the foot upon the base of the tibia will aggravate the pain intensely; it is, however, necessary to make this pressure upon all parts; you may, perhaps, press upward and you get no pain; then press out on either side of the astragalus in order to bring the sides of this bone against the malleoli; so make your pressure on all sides to bring all parts of the joint into contact. Now if, on the contrary, you get a release from pain by pressure, and upon extension you get more pain, then the disease is in the ligaments; by this simple plan you can diagnosticate your case.

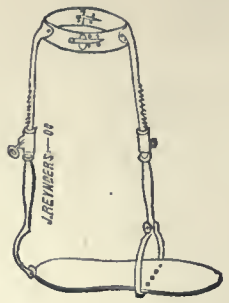
In the very early stage of the disease you will find slight swelling and slight increase of temperature of the parts, but in some cases the increase of temperature is not perceptible to the sensibility of the touch; in such cases use Seguin's surface thermometer; by this means you can detect the exact point of the disease, and secure an accurate registration of temperature.

Treatment.—In the first stage, in all sprains or injuries of a like nature, dip the foot in hot water, as hot as the patient can bear it; then every few minutes add a little more water still hotter, and so on until your patient may perhaps be able to bear it at 120° F., so hot, indeed, that he cannot bear that amount of heat with the other foot if put in the water at once; this will remove the pain almost entirely; this should be continued without intermission for six or eight hours, or until the parts can bear pressure without pain: if you will do this at the outset, you will save yourself much trouble and the patient many months of pain. After you have accomplished this, take a roller bandage and commence to bandage the foot at the distal extremity, in order to drive the blood before you, and never under any circumstances make a turn of the bandage tighter above than below, but keep equable pressure on all parts and thus avoid strangulation.

The mother, in this case, took this child to a medical gentleman, although at that time she states there were no external appearances of disease of the joint; the doctor, however, applied the plaster-of-Paris bandage, and the result is as you see; it did not arrest the disease, notwithstanding it was immovably secured in the plaster bandage, and this, although preventing motion in the joint, has not prevented the pressure of the articular surfaces together within the joint; this being the natural result of reflex muscular action, and hence the application of the plaster-of-Paris bandage is inappropriate in such cases.

When this child was brought to me the joint was much larger than it is now: pressure upon the heel or the least attempt to flex the foot produced intense agony. I advised the application of *cold*-water bandages, which have considerably reduced the swelling and inflammation. I have here a small instrument by which I shall now secure my extension and counter-

extension. This consists of a small steel foot-plate with an anterior and posterior rod attached above to a small collar which passes around the leg just below the knee; these rods being composed of two bars sliding upon each other, are regulated by a ratchet and key (see Fig.).



Now in applying this instrument I first fold a small piece of cloth, and lay it upon the foot-plate, for the purpose of absorbing all moisture, then passing this under the foot, I bring a strip of adhesive plaster from the heel of the instrument over the instep; I then secure the sole of the foot to the instrument by smaller bands of plaster passing across the foot, as you observe. I now take a strip of the plaster and pass it around the heel, bringing the two ends forward, which I pass around the sides of this small steel arch of the instrument which supports the anterior rod; then drawing the heel well forward, I reverse the ends of the plaster upon itself. Having now secured the foot in this manner, I now apply a roller bandage, securing equable pressure upon all parts of the foot. We now take long strips of adhesive plaster and pass them up the leg from just above the ankle-joint, taking care that they are not brought too close to the erosion which you observe at that point; then apply a roller bandage firmly around the leg, and having done this, attach the collar of the instrument, putting underneath at the anterior portion two small pads to protect the tibia from undue pressure; now reverse the ends of the adhesive plaster over this collar, and in turn secure them with a few turns of the roller; and now, having accomplished this, we are prepared to make extension and counter-extension. You will observe that all this time I have left the *ankle-joint exposed;* we can now make our extension, this being gradually effected, first at the heel, then at the toes, until the foot is brought at a right angle to the leg, and the requisite extension secured; at which point the child is free from pain, the articular surfaces being removed from each other. In this case I am compelled to use quite a little force, as the gastrocnemius is rigidly contracted, but I use the force gently and gradually: never use violence with an inflamed muscle. I have now completed my extension, and, as you observe, have left the ankle-joint exposed. Now were I to let it remain in that condition, I should leave the joint open to extravasation of blood, and I might do the child more harm than had I let him alone. I therefore take these strips of adhesive plaster and draw them around the joint as tightly as I can. I then apply this roller bandage and draw equally as tight, and by this pressure I expect to promote absorption of the exudation in the joint. In placing the shoe upon the foot, cut the shoe open behind and in front to admit the rods, then putting in eyelets, lace them behind the rods; in this manner the shoe is applied neatly and comfortably.

This child can now run around in the open air to improve his general condition; at the same time he should be properly nourished.

CASE II. *Chronic Disease of Ankle-joint.*—This little fellow was brought to me two days ago suffering from the same disease, but in a more aggravated form. His difficulty arose from an injury received at the ankle by falling down some eight or more steps. When I saw him the ankle was swelled to such an extent that I was afraid it would burst; I immediately ordered the application of a cold-water sponge compress, which was faithfully applied, and I am pleased to notice the improved condition of the joint. I will make extension of the joint here, and while retaining it in that position apply the sponge compress; this should be firmly and snugly secured, and then, having done that, dip the foot in water; the water being absorbed by the sponge, causes additional pressure upon the joint, and by this means favors absorption of the exudate.

When this disease has been further reduced I shall apply the extension and counter-extension by the same means as in the previous case.

CASE III. *Clubfoot, Talipes Equino-varus.*—I have here a little child suffering from club-foot, and I take this opportunity of drawing your attention to this point, that when performing the operation of tenotomy you secure a proper instrument with which to sever the tissues. I omitted to bring my own tenotome with me, and the house surgeon has just handed me this one, which, you observe, has a sharp point. I consider that any man using this incurs a great risk. I would not use this instrument under any consideration, and yet I consider that I can cut a tendon without injuring the vessels that may be in proximity to it as well as any one, but with all of my practical knowledge I would not undertake to use this tenotome. You will find this instrument in the shop of almost every surgical instrument maker, but it is not fit to use in the operation of tenotomy. (Dr. S. having sent to his office for his tenotome, it was now handed to him.)

The tenotome which I use, you will observe, is curved and round-pointed, and thus you can avoid injury to the vessels while performing the operation. The child now before us is suffering from the form of talipes known as talipes equino-varus; this condition in this case is congenital. I will now endeavor to bring the foot into the normal position by section of both the tendo Achillis and plantar fascia. You will observe that, as my assistant brings these muscles upon the stretch, I make point pressure upon each one, and instantly there is produced a reflex spasm of these muscles, thus indicating that they must be severed before any satisfactory result can be obtained. I will first divide the plantar fascia, and here you will observe that I pass the blade of the knife under the contractured tendon and fascia, with the blade lying flat against them. Having now inserted it to the desired point, I turn the edge towards the fascia, and with a short sawing motion, and with firm pressure of my thumb upon the stretched tissues, I have completely severed the plantar fascia. I then instantly return the blade to the flat position and withdraw it, placing my thumb over the wound, as I do so to prevent the entrance of air; it is then hermetically sealed with a strip of adhesive plaster. I will now sever the tendo Achillis in precisely the same manner (the tendo Achillis was then severed). Having now secured both tendons and closed the wounds, we take this small piece of board, which is the width of the foot and extends a little beyond the toes, having at its anterior end a broad strip of adhesive plaster; you also observe that there are one posterior and two lateral strips of the plaster, the board being well padded, as is my usual custom. This we now secure firmly to the foot by means of the plaster strips, and taking this roller bandage bind it firmly around the foot, passing gradually up the leg; but you will here take notice that I

have secured a strip of adhesive plaster passing from the sole of the foot to the outer side of the leg up to the knee, in order to evert the foot and retain it in its normal position, while from the anterior portion of the foot passes this broad band of adhesive plaster up to the leg, and which secures the foot at right angles, these strips in turn being securely held by the roller bandage. In this case I shall extend my bandage up to the thigh, the child being so small.

This is the entire treatment of tenotomy in these cases of clubfoot. You have seen that I place the foot in its normal position immediately after section of the tendons, and to this I especially call your attention; other authorities, after having severed the tendons, bind the foot up in its deformed position, and after the wound has healed, commence gradual traction upon the severed tendons and endeavor to restore the foot to its normal position by this means; that is the essential difference in my mode of treatment.

After I have restored the foot to its normal position, the exudation from the severed muscles forms a connection between the two cut surfaces and which binds them firmly together, and in this manner I secure a useful and contractile muscle and without causing the slightest pain. On the other hand, were I to make traction upon the new growth, the pain would be so severe that I should have to desist, or, were I to restore the foot to its normal position, I should have so strained the new growth between the two cut surfaces as to render it perfectly useless, had I not torn it asunder in making the traction. I have followed this plan of treatment for upwards of twenty years and have secured the most successful and satisfactory results from the same. I will bring this child again before you in order that you may fully verify my method of treatment.

Note 1.—A week has now elapsed since the operation upon this child for talipes equino-varus. The mother now informs us the patient has not suffered in any manner from the operation; sleeping well at night and making no complaint during the day. Before removing the dressing, you will observe the toes of the foot retain their natural color, showing that the dressing was not applied too tightly. We will now remove the dressing and note the result of the operation (dressing was then removed). You can here notice that the foot is at right angles and the wounds completely healed. By pinching the gastrocnemius, I secure such contraction of the muscle as to raise the heel, showing that union has taken place between the severed ends of the tendo Achillis. I will now reapply the dressing as before. I wish, however, to call your attention to this point; before applying the bandage, bring the foot to a right angle so that your pressure may be adapted to the vessels of the foot at the angle at which you wish to retain it; by this means you avoid the constriction you would be liable to incur if the foot were flexed after the bandage was applied. In these small children, remember to let the bandage extend up upon the thigh. You will observe that I pass a strip of bandage from the sole of the foot to the outer part of the leg, in order to guide the foot in the direction I desire it to retain. The child can now wear this bandage for some few weeks, or until the parts have become thoroughly organized and can bear the weight of the body; then, if necessary, mechanical treatment can be applied.

Note 2.—The following week the bandage was again removed. On removing the bandage I find no sloughing here whatever, and the wound, as you observe, is entirely closed, the foot is at right angles, and there is no deformity whatever. The only difficulty now is the weakness of the muscles, but that can be remedied by the following method. This boy is now in a condition for the application of my clubfoot shoe. This shoe has in the sole a hinge capable of flexion, extension, inversion, and eversion; to a certain degree this is regulated by elastic bands, which can be so arranged as to flex or evert the foot in the desired position but not so strongly as to prevent the foot being moved in the opposite direction at the will of the patient.

Having now performed the operative part of the treatment, we require to restore vitality to the muscles and retain the foot in the normal position; now in this case, all that is required is to furnish the foot with artificial muscles to evert it and bring it to a right angle, and these are supplied in the mechanism of the shoe the boy will now wear. In the summer-time he can run around barefoot and thus aid in strengthening and restoring vitality to the muscles.

CASE IV. *Talipes Varus.*—I here present to you this young girl, eighteen years of age, suffering from talipes varus in its worst possible form; in this case it is congenital. Upon putting the tendo Achillis and plantar fascia upon the stretch, and making point pressure, you here observe I get a reflex spasm.

The tendo Achillis has been divided twice previously, but the plantar fascia has been neglected; the first operation was performed when she was three months old, and the second division was made when she was about three years of age. At both operations the foot was bandaged in its deformed position instead of bringing it into the normal position at the time the operation was performed. After the wound was healed traction was made upon the severed muscle to endeavor to bring the foot to a more natural position, but the pain was so intense that it had to be abandoned, and the result is as you now see—one of the worst forms of deformity, the foot being turned in at a complete right angle. Now at the first operation, had the plantar fascia and tendo Achillis both been severed, and the foot restored to the normal position immediately, as you saw me recently treat that little child, this young girl would have been enabled to walk with grace and ease, and could have been cured without deformity; whereas at the present time she is now compelled to walk upon the external malleolus of this left foot, and the pain of walking on this unnatural support, even for a short time, will confine her to the house for some days after, rendering the limb perfectly useless as a means of locomotion.

I find here a dislocation of the scaphoid bone; the question now arises whether by dividing the plantar fascia, I can reduce that dislocation? You observe that there is a reflex spasm upon point pressure being made upon this fascia, showing the necessity of section before anything can be done; then would arise another question as to whether, after section has been made, I can restore the foot to its normal position without making exsection of the bone itself, and taking out a V-shaped piece; in many cases that has to be done. Since Mr. Lister's day, we can perform this operation with impunity; we can take out a V-section of the metatarsal bones and secure union without the formation of a single drop of pus. Now this may seem strange, but it is a fact, and has been done since Mr. Lister's antiseptic treatment has been introduced. I look upon this antiseptic mode of treatment as one of the greatest successes in our surgery of the present day. If that could not be done, then comes the question of amputation, but I would not resort to amputation until I had tried all other means. At present, the patient is not in a condition for an operation; there is a bursa here at the external malleolus, which is very much inflamed, and were I to operate now, it might be followed by disastrous results; I shall therefore advise her to avoid using the foot for a time, keeping cold-water applications upon this bursa, and upon her return to me, I will divide both the tendo Achillis and plantar fascia, and if it is necessary to make a V-section of the bone,

I will do so, as I think it will be vastly better to perform this operation. If amputation should after all be decided upon, I should prefer a modification of Simes' operation by Prof. Bryant, and that is, to saw through the condyles, and also the os calcis, then bring these surfaces together, having the posterior portion of the os calcis in the flap, which would make an excellent and desirable support for the limb.

ORIGINAL ARTICLES.

THE DIAGNOSIS OF CONSUMPTION BY MEANS OF THE MICROSCOPE.

BY H. GRADLE, M.D., AND H. WOLTMANN, M.D., OF CHICAGO.

(*Read before the Chicago Medical Society, Jan. 8, 1883.*)

THE subject which we wish to bring to the notice of the Society to-night is the recognition of pulmonary tuberculosis by examination of the sputum. The microscope can, of course, decide the tubercular origin of a sputum only, if the latter contains some characteristic structural element never found under other circumstances. Such a pathognomonic constituent is the *Bacillus tuberculosis*, recently described by Koch. This observer, now well recognized as the foremost investigator of bacteria, has found in all tubercles a well-characterized parasite, which he has never encountered in any other healthy or morbid tissues.

Though it is to be presumed that the profession is now quite familiar with Koch's investigations, it may be best to point out once more the salient points of his discovery, preliminary to our further remarks. The bacillus tuberculosis, as Koch describes it, is a delicate rod, one-third or half as long as a human red-blood corpuscle, characterized not only by its shape and dimensions, but much more so by its behavior to staining agents, for the ordinary mode of aniline staining fails entirely to demonstrate its presence. It is only by a more complicated procedure, devised by Koch, that it can be colored at all, and hence recognized. Since this staining method was original with Koch, and since the unstained parasite does not attract the attention, on account of its faint outlines, we have a sufficient explanation why no one has seen it with certainty prior to Koch. The claim of this observer regarding the connection of this parasite with tuberculosis, is based on the examination of 11 cases of miliary tuberculosis, 12 of caseous pneumonia, 1 of tubercular tumor of the brain, 2 of intestinal tuberculosis, 3 of scrofulous glands, and 4 cases of fungous inflammation of joints in man. Besides this, he examined numerous cases of pearl-disease in cattle, a number of instances of spontaneous tuberculosis in animals, and no less than 200 animal victims which had been inoculated with tuberculous material. Amongst this overwhelming array of material he did not fail in a single instance in finding this particular parasite, whereas he could *not* discover it in any other morbid products.

The coincidence of this micro-organism with tuberculosis would not alone prove its causal relation to that disease. This proof, however, Koch *has* furnished by producing tuberculosis in numerous animals *invariably* by inoculating them with the isolated bacillus. It was well known previously that the infection with tubercular material produces tuberculosis in animals, but Koch was the first to show that this result could be obtained *with absolute certainty* with the bacilli alone freed from all adherent animal substances. This parasite, unlike the bacteria of putrefaction, will not grow in the solutions commonly used for bacterial cultivation. It could be cultivated only on the surface of solidified blood serum, at a temperature ranging from 30° C. to 41° C. On this surface it forms brittle, scaly masses, growing very slowly, and presenting a characteristic appearance. All the characteristic properties of the parasite remained unchanged, no matter how long it was cultivated on this artificial surface, or how often it was transferred to a fresh soil. Inoculation of animals with the parasite cultivated in eight successive generations gave the same results as infection with the original tubercular matter. To any one familiar with bacterial investigations, the proofs furnished by Koch of the parasitic origin of tuberculosis cannot but appear as positive as any experimental results can be without mathematical verification.

But as yet this entire doctrine regarding the etiology of tuberculosis rests upon Koch's assertions; backed, however, by his unrivalled reputation for accuracy. His publications are too recent to have received much confirmation, though Korab in France, and Sternberg in this country, have made short communications corroborative of Koch's experiments. The mere fact, however, that Koch's bacillus is present in all tuberculous products can be readily confirmed by any one endowed with sufficient patience. Ehrlich was the first to show that this parasite is always found in tuberculous sputum, and not in the expectoration of non-tubercular patients. He based his paper on the examination of twenty-six tubercular cases by means of a method of staining more convenient than the original one of Koch. Subsequently Gibbes modified Ehrlich's method slightly, and published further results corroborative of Ehrlich. The latest publication is that of Balmer and Fraentzel in the *Berliner klinische Wochenschrift* (No. 45, 1882), who never failed to find the parasite in the sputa of 120 phthisical patients, without ever detecting it in other diseases.

But Koch has also met with opposition on the part of Dr. Formad and Dr. Schmidt. The former relates some interesting observations on the minute anatomy of tubercular patients (*Philadelphia Medical Times*, November 18, 1882). If his assertions are fully sustained by a more detailed description of his researches than he has yet given, they will form a most valuable contribution to the pathology of tuberculosis. In fact, they would furnish us with an anatomical basis for the predisposition to that disease. For it has always been known, that not *all* human individuals and not all species of animals are equally susceptible to tubercular infection. But Formad takes this opportunity to attack Koch's conclusions as to the parasitic origin of the disease without disproving a single one of Koch's

facts. In his own statements there is no evidence that he has made any personal observations on the presence or the significance of the bacillus tuberculosis. Although he has discovered some conditions said to exist in all subjects predisposed to tuberculosis, he has not proven that these conditions alone can bring on the disease. Nor has he shown that the disease ever occurs without the presence of the parasite in question. But, he says, tuberculosis can and does occur in subjects predisposed to it, from inoculation with other than tubercular matter. True enough. But Cohnheim, who has once upheld the same view, subsequently admitted that his rabbits became tubercular apparently without *specific* infection only in localities where other tubercular animals were kept. If the tubercular parasites were not disseminated except by the experimental inoculation with the tubercular matter, the disease would soon be extinct. The point in question might be illustrated with a homely analogy which we hope, however, is not inapt. Inoculation with smallpox crusts is recognized as a sure way of reproducing that disease in all individuals susceptible to it. Yet at the time of an epidemic the inoculation with entirely different and harmless substances might be followed by smallpox, if the susceptible individual were otherwise exposed to the contagion. Similarly in the case of tubercular infection. But while the occurrence of tuberculosis in rabbits, animals so predisposed to the disease, is an accident—to say the least—after the introduction of non-tuberculous substances, it is the *invariable* consequence of an injection of Koch's bacillus. No matter, however, whether the disease is produced by the intentional introduction of the parasite, or whether the latter enters the system by an accident beyond the control of the observer, the parasite is there in every case. Koch, moreover, found that even species not at all liable to acquire spontaneous tuberculosis always succumbed to infection with the isolated parasite, simply because thus a larger number of bacilli were introduced. The growth of this microorganism is so slow that it is often eliminated from superficial wounds, without gaining a foothold in the animal body. Hence Koch preferred the more certain way of infection, viz.: by injection into the interior of the body of the animal. Formad questions Koch's motives in thus preferring injections into the peritoneal cavity and anterior chamber of the eye. But the reasons, above pointed out, he might have found in Koch's original article. On the other hand, it might be asked of Formad whether he or any one else has ever seen *local* tuberculosis (*i. e.*, of the iris) in consequence of the introduction of non-tubercular matter *into the eye*, even in as susceptible an animal as the rabbit.

Dr. Schmidt, an excellent microscopist, has attacked Koch on other grounds. He claims that the bacilli are nothing but fat-crystals. That fat-crystals can be seen in specimens treated, according to Schmidt, with a solution of caustic potash is not unlikely; in fact, we have seen similar crystals in such specimens. But they are wholly irrelevant to the point. A comparison of Schmidt's description and drawings with the specimens which we here present, will convince the Society that Schmidt has never seen the bacillus tuberculosis. It is not possible to confound crystals of such different appearance and dimensions with the bacilli stained by any of the various published methods correctly employed. It is not evident from Schmidt's article (*Chicago Med. Journal and Examiner*, Dec. 1882), whether he has followed these methods accurately or not, but, at any rate, he has not had any success with them. The query of Dr. Schmidt, why the bacillus tuberculosis stains differently from other bacilli (and the vague assertion of Dr. Formad that it does not), cannot weigh in opposition to the positive statement by the discoverer that such *is* the case, a statement fully confirmed by Ehrlich, Gibbes, Sternberg, Balmer and Fraentzel, and ourselves.

In order to demonstrate the presence of the bacillus tuberculosis in sputum, the latter should be dried on a cover-glass, in the thinnest layer possible. In order to prevent its being washed away by further manipulations, it is then to be rendered insoluble by passing it several times through a flame. One soon learns by experience how much it is to be heated. It is now ready for staining. In Koch's original article he recommends using an alkaline solution of methyl-blue for this purpose; the addition of an alkali is necessary in order to color the bacillus at all, though other aniline colors can be substituted for the methyl-blue, but with less success. On treating the specimen thus prepared with a solution of vesuvin, the brown color of the latter takes the place of the original blue in all the structural elements except the bacilli, which remain blue. This method seems to be the most difficult one to realize. We have had but indifferent success with it, especially as we could not obtain the colors used by Koch. Ehrlich substituted aniline oil for the potash in Koch's solution, dissolving this in water to the extent of its solubility. To this solution methyl-violet or magenta is added, and the specimen is then exposed for half an hour. The advantages obtained by Ehrlich are, first, a shorter time of exposure; and, secondly, greater reliability in the hands of an inexpert observer. The specimen is then decolorized by means of nitric acid. When the color has faded out of all other parts of the specimen, the bacilli still retain it, but their distinctness is improved by restaining the ground with some contrasting color in neutral solution. Ehrlich's method necessitates fresh preparation every time the solution is used; this, Gibbes has sought to avoid by using alcohol, which keeps the aniline oil in more permanent solution. But Gibbes' proportions of the various ingredients have not proven reliable in our hands. Mr. Woltmann has devised a modification of Ehrlich's method which we have found most serviceable. It amounts, practically, to a dilution of Gibbes' solution, with the addition of more aniline oil. Two grms. of magenta crystals are dissolved in a mixture of five grms. of aniline oil and twenty grms. of alcohol. Gradually, twenty grms. of distilled water are added. This solution is then filtered and kept permanently as stock. When required for use, one part of it is diluted with thirty parts of distilled water, and put

into a watch-glass; the cover-glass, with the dried sputum, is allowed to float upon the surface of this liquid. The time of exposure must be at least three hours with our dilute solution; but when the bacilli are present in limited number, a longer action of the staining-fluid, up to twenty-four hours, is more reliable; which has also been the experience of Balmer and Fraentzel. Good staining of the bacilli is favored by a temperature of about 40° C. We have always kept our specimens in a warm chamber. The glass is then washed in a current of water, and immersed in nitric acid diluted with twice its bulk of water. It is kept there just long enough to take all visible color out of it, whereupon the acid is again washed away with water. Under this treatment the bacilli retain their distinct red tint. They attract the eye more, however, if the ground be now stained blue. We accomplish this by a two minutes' exposure to a two per cent. solution of aniline blue (commercially known as 3 B. C.), the surplus of which is washed away. After drying by gentle heat, the specimen is mounted temporarily in spirits of turpentine, or permanently in Canada balsam. In it the animal-cells and mucus are blue, while the bacilli appear distinctly red. Other microorganisms, if present in small numbers, are not stained enough to attract attention; at any rate, they are never red. A good one-fifth inch objective suffices to see the bacilli, but a bright illumination without a diaphragm is absolutely necessary. It is much easier to recognize the bacilli when an Abbe's condenser is used; in fact, when the bacilli are few in number the examination is not reliable without it. In default of this, a short-focused objective may be attached to the substage as an imperfect substitute.

The bacilli correspond exactly to Koch's description. In some instances they are found in a state of sporification, which, observed with low powers, makes them appear granular. They are often slightly curved, and many pairs are seen in the form of a figure V.

Our own results are in full confirmation with those obtained by Koch and all other European observers. We have never seen the bacillus tuberculosis, or anything which could be mistaken for it, in the sputum of non-tuberculous patients. We have always found it in sputum of phthisical origin. We have likewise observed it in cases in which the rational symptoms pointed decidedly toward tuberculosis, while an examination of the chest gave ambiguous results; and we are convinced that time will prove the correctness of our diagnosis in these instances. We have, hence, no hesitation in claiming for the microscopic examination of sputum, *that it is the earliest and most reliable test for tuberculosis.* Like Balmer and Fraentzel, we have also found that the number of bacilli in the sputum gives some indication of the degree of intensity of the disease. They are, however, not evenly distributed throughout the sputum; hence it is best to examine several slides made from different portions in all questionable cases, and when they cannot be found the first time, the examination should be repeated on a subsequent day. It is, of course, essential that the sputum should come from the lung, and not from the upper air-passages.

The inevitable conclusions from our own work, as well as that of other observers, are that

Every case of pulmonary tuberculosis can be diagnosticated by means of microscopic examination of the sputum, even before the clinical examination reveals it with certainty; and that, *When repeated proper examination of the sputum fails to show the bacillus tuberculosis, pulmonary tuberculosis does not exist.*

To speak with certainty in any case requires, of course, that the observer should have familiarized himself with the methods and possess the proper appliances. Our success has been so invariable, that we feel confident enough to challenge the Society to produce a case of tuberculosis in which we cannot demonstrate the bacilli. Moreover, we are prepared to examine a reasonable number of sputa furnished to us without clinical histories, as the test of our assertions, and to submit the results of this examination to the Society at the next meeting.

A CASE OF DEATH FROM CHLOROFORM.

By J. EDWIN MICHAEL, M.D.,

PROFESSOR OF ANATOMY AND CLINICAL SURGERY IN THE UNIVERSITY OF MARYLAND, BALTIMORE.

Samuel Y., colored, cook, aged about 50, came under my treatment a few weeks ago for stricture of the urethra. He was admitted to the Maryland University Hospital a short time before the beginning of my time of service (Jan. 1), under the care of my colleague, Prof. L. McLane Tiffany, with the following history. About seven years ago he suffered from difficulty in passing water, due to a previous gonorrhœa, and came to the University Dispensary for relief, where he was treated by Prof. Christopher Johnston. The operation then performed upon him, according to his own description, was that of rapid dilation by the instrument of Holt. This treatment was eminently successful, but failing to follow Prof. J's. directions to come from time to time and have an instrument passed, his stricture returned, and about four years ago he applied to the late Prof. Thomas R. Brown, of the College of Physicians and Surgeons, of this city, and was again successfully treated, this time by the internal cutting operation of Otis. Again neglecting to follow instructions, his trouble gradually returned and his condition changed from bad to worse, until his admission to hospital. Even then he was not admitted on account of his urinary trouble, but for an injury to the foot which he had sustained. When attention was called to the condition of his urethra, it was found that he could only pass his water by drops, and that with great straining. He was much emaciated and suffered frequently from chills and rigors. An examination of his urine revealed the presence of tube-casts and albumen. His appetite was poor, his sleep restless and unsatisfactory, and his general condition exceedingly bad, though no other organic disease was discovered. A full-sized instrument was checked at the bulbo-

membranous portion of the urethra, and external examination showed a large hard lump at a corresponding point; smaller instruments were tried until a long and patient trial of a number of the finest filiform bougies failed to reveal a passage. As the bladder was not much distended, and the patient could still relieve himself in some degree, aspiration was not deemed necessary. Appropriate treatment was ordered, and instructions given to the house physician to aspirate later if necessary. After several days of rest, during which there was sensible improvement in the patient's general condition, another search for the passage to the bladder was undertaken. After a long and patient trial I was again defeated, and pronounced the stricture impassable, at least so far as I was concerned. I therefore, having explained the serious state of affairs to the patient, and placed the whole matter before him as clearly as possible, advised external perineal urethrotomy without a guide. He consented after deliberation, and I determined to operate on Friday, January 12, at my clinic. Chloroform was the anæsthetic selected. Twenty minutes before the beginning of the inhalation one ounce of whiskey was administered, according to a practice which I always follow in using chloroform with adults. Another ounce was given at the beginning of the inhalation. The anæsthetic was administered by the two resident physicians, Drs. West and Mitchell, both of whom have had ample experience, and in whose skill and judgment I have every confidence. I requested them to be exceptionally careful in this case, on account of the desperate condition of the patient, and I am convinced that my injunction was carried out to the letter. The chloroform used was Squibb's; the apparatus, a towel cone open at both ends. The inhalation proceeded in the ante-room, while I explained the nature of the case and the proposed operation to the class. I had made but few remarks, however, when I was hurriedly called from the clinical theatre by Dr. West, and informed that the pulse had suddenly ceased. By the time I reached the ante-room, the lower extremities were well elevated, the head hung over the end of the operating table; hypodermic syringes filled with whiskey ready to be applied, and the battery in the corner of the room clicking away ready for use. Artificial respiration was being practised with success, as far as causing the ingress and egress of air to and from the lungs was concerned. My opinion, when I saw the state of the case, coincided with that expressed by Dr. W., that it was a death from heart paralysis, and that all efforts at resuscitation would be vain. The means at hand were however faithfully used for fifty minutes after the abrupt cessation of the pulse, but without the slightest response. Respiration could be produced both with the hand on the sternum and the battery, but no heart sounds could be heard nor the slightest pulsation elicited. Hypodermic injections were used, but only sparingly, since they evidently could do no good without a circulation. The death occurred early in the inhalation, as is the rule in cases of this kind. The patient was by no means fully under the influence of the anæsthetic, but still in the stage of excitement. The pulse ceased as he was making an effort to rise from the table. About three drachms (estimated) of chloroform had been poured in the cone.

Autopsy, five hours after death, made by Dr. W. T. Councilman. The abdominal cavity was opened and the digestive tract, which presented nothing worthy of note, first examined. Trachea contained a little frothy mucus. Lungs contained some insignificant patches of old emphysema. They were congested in a high degree, and bled (when incised after examination of the heart) very freely. Heart about normal in external appearance; right side distended, as also venæ cavæ and pulmonary artery, with fluid blood. Left ventricle very slightly (?) hypertrophied, containing, as also auricle, small quantity of fluid blood. Heart tissue (macroscopically) perfectly sound. All orifices and valves perfectly normal. Liver highly congested, and bleeding freely on incision. Right kidney somewhat contracted, pelvis dilated and thickened to a considerable degree, as also right ureter throughout its whole extent. Left kidney firmer than normal to the feel, but not otherwise changed. Capsules of both kidneys slightly adherent. Bladder contained something over a pint of urine; walls thickened considerably; slight tendency to sacculation. Follicular cystitis, especially in the trigone. Moderate prostatic hypertrophy. Urethra, anterior portion of prostatic and two-thirds of membanous portion largely dilated. Stricture occupying about three-quarters of an inch at bulbo-membranous portion; pendulous portion normal. The stricture was a somewhat notable one, as was to be expected after the use of both Holt's and Otis's instruments, and subsequent recontraction. The urethra, above and below, came to irregular points, somewhat overlapping each other, and urine seemed to pass through a sort of cribriform septum between them. Dr. Councilman was unable to find a regular passage through it. Brain and cord were not examined, as it was deemed unnecessary.

Remarks.—Although I may say I have been living in an atmosphere flavored with chloroform for the past ten years, this is the first (and I need not say I sincerely hope it will be the last) death I have seen occasioned by the drug. That the anæsthetic killed the patient, I think is equally apparent from the clinical events and the post-mortem details given above, and that the fatal end was reached by way of paralysis of the heart I consider beyond doubt. That this kind of death will occasionally occur from the use of chloroform, the most enthusiastic admirer of the drug cannot deny. The chloroform used was that generally acknowledged to be the purest in the market; previous alcoholic stimulation was resorted to with special reference to heart failure; those who administered the drug were careful, experienced, and competent; the apparatus used was the simplest and safest, and the means most in vogue for resuscitation were at hand, and were used promptly and skilfully when the emergency came. Moreover, I have used the same chloroform, at the hands of the same assistants, both before and since this unfortunate case, with most satisfactory effect. The occurrence of the case in my practice has only illus-

trated what I knew had occurred before, and could occur to any one who uses chloroform for the induction of anæsthesia. Whether there is less danger in the use of sulphuric ether, ethyl bromide, or other anæsthetics, I shall not, in this place, attempt to discuss. I consider it my duty, however, to report my case as a contribution to the mass of facts bearing on the question, and hope, in common with other surgeons, that we may ultimately, by the collection and comparison of *all* the facts, be enabled to definitely decide the question as to what is the safest and the best anæsthetic.

HOSPITAL NOTES.

VIENNA GENERAL HOSPITAL.

(Service of PROF. CARL BRAUN.)

A HIGH FORCEPS OPERATION.

(Specially reported for THE MEDICAL NEWS.)

A CASE of the high operation which Prof. Carl Braun performed upon Wednesday, November 8, before the class will serve to convey the teachings of the Vienna School upon a number of important subjects in relation to the use of forceps.

The patient, a native of Austria, unmarried, thirty-two years old, in her fifth pregnancy at full term, felt labor pains towards the evening of November 7, and entered the lying-in ward of the First Obstetrical Clinic at 2.30 A.M. November 8. Abdominal palpation revealed pregnancy at full term, a large child, head presentation, first position. Heart tones were loud and regular. By combined external and vaginal examination a contracted pelvis was demonstrated. The measurements were:

Distance between the anterior and superior spine,	21½ cm.
Distance between the iliac crests,	25½ "
" " trochanters,	30½ "
External conjugate diameter,	18 "
True " "	8½ "
Abdominal circumference,	82 "

The os became fully dilated at 5 o'clock A.M., and the rupture of the bag of waters occurred some moments later. The head engaged in the superior strait and advanced very slowly until a segment of one-third its volume was within the pelvic cavity. The head now became firmly fixed, with the sagittal suture in the transverse diameter, and a considerable caput succedaneum began to form. The corpus uteri continued to contract powerfully, at regular intervals, without effecting in the slightest degree any change in the position of the head, while the collum uteri became distended, and finally reached to the umbilicus. Later the condition of tetanus uteri was observed, and the corpus uteri could be felt as a firm hard tumor above the umbilicus, very sharply differentiated from the distended, relaxed collum uteri, situated below. At 11.30 o'clock A.M., the woman received a hypodermic injection of morphia, and at 12.30 o'clock P.M., she was taken into the lecture-room for the application of the forceps.

Prof. Braun, after careful disinfection of his hands by liberal use of a 3 per cent. solution of carbolic acid, 10 per cent. solution of potassium permanganate, a solution of hydrochloric acid of similar strength, green soap and a brush, examined the woman, and confirmed the diagnosis previously made in the lying-in ward. He said the child would weigh more than 3500 grammes, and would have a greater length than 50 cm. After catheterization, the vagina and external genitals of the patient were copiously irrigated with a 3 per cent. solution of carbolic acid, immediately before the application of the forceps.

While Prof. Braun is in no sense of the word a strict disciple of Lister, he is no disbeliever, and always gives his patient the benefit of a doubt, with the exception of the spray. In passing, it may be mentioned that careful irrigation with disinfectant fluids was employed under his direction long before Esmarch called public attention to the subject.

For the operation, Prof. Braun selected his own instrument. This is the long forceps of Sir James Simpson, with the fenestræ closed by a thin metallic plate (Hohl's modification), the whole instrument, including handles, being covered by a thin layer of hard rubber. The weight of the instrument is 600 grammes.

The advantages claimed for the instrument are:

1. The impermeable, smooth surface.
2. The easy, antiseptic cleansing, because septic material finds no lodgement in any groove.
3. The durability, because hard rubber resists rust, chloroform, chloride of iron, carbolic alcohol, which is not the case with the nickel or gold-plated instrument.
4. The instrument requires no heating apparatus.
5. The avoidance of all sharp, metallic angles and points, which injure the skin of the head and face.
6. The obliteration of the fenestræ prevents the feathering of the blade.

Prof. Braun speaks in unmitigated terms of disapprobation against Tarnier's forceps, Alexander Simpson's instrument, and Felsenreich's modification of the last-named forceps. Felsenreich's forceps, which have been used at the clinic for some months past, present few points of difference from Alexander Simpson's original instrument. For the past six months there has been much discussion in the Vienna Obstetrical Societies as to the value of the last-named three instruments. For this reason, Prof. Braun has allowed his assistants to use them at the clinic. The results, upon the whole, have not been favorable. Mother and child have, in a number of cases, sustained serious injury. Prof. Braun himself never uses the instruments, and pronounces the principle to be radically false, and the instruments themselves a fashionable folly ("Moderner Schwindel").

The patient having been slightly chloroformed, was placed upon her back, with her lower extremities elevated, and the blades of the forceps were adapted to the long diameter of the fœtal head, the maternal tissue being guarded by the introduction of four fingers above the pelvic brim. Seated quietly in his chair, the operator applied traction in the axis of the pelvic brim, and after a few, though sometimes powerful, efforts, brought the head down into the middle of the pelvic canal, where rotation was effected by readjustment of the blades, and the birth of the child rapidly followed.

Prof. Braun never used the forceps as a *lever* or *compressor*.

The child proved to be a male, weighing 3900 grm. with a length of 52 centimetres. The child was profoundly asphyxiated, but when the cerebral congestion was relieved by its elevation above the level of the placenta, the breathing became normal, and the facial hyperæmia disappeared. The placenta was at once expelled, the corpus uteri being thrust downwards towards the symphysis in such a manner as to cause complete descent of the collum uteri into the cervical canal. The collum uteri folded upon itself as if telescoped.

When the cord ceased to pulsate, 30 minutes after its delivery, it was severed, but not ligated. This departure from custom was made, in order to show that liga-

ture of the cord, after cessation of pulsation, is not a scientific necessity.

Prof. Braun is not an iconoclast, however, and in the lying-in ward all umbilical ends are ligated in two places. After careful irrigation of the vagina with a 3 per cent. solution of carbolic acid, an iodoform tent, weighing 5 grammes, was introduced into the uterus.

At the time of writing, both mother and child are thriving.

MEDICAL PROGRESS.

Tuberculosis of the Fallopian Tubes.—Dr. Justus Schramm, of Dresden, contributes to a recent number of the *Archiv für Gynäkologie* a short paper on the above subject. Out of 3386 autopsies upon women, he found this condition present 34 times, or about 1 per cent. There were of these, 806 who died from pulmonary phthisis or from tuberculosis of other organs, so that the proportion in which the tubes were affected in them was 4.2 per cent. In the 34 cases of tuberculosis of the tubes, the uterus was affected 7 times, there was tubercular disease of the peritoneum 21 times, and more or less advanced lung disease in 29. Both tubes were diseased in 27 of the cases, the left alone in 5, the right alone in 2. The large majority of Dr. Schramm's cases occurred between the ages of twenty and forty. In only one of the 34 was there reason to think that the disease of the tubes was primary; but in this case the bowel and peritoneum were also affected, the greater amount of disease in the tubes being the only reason for thinking them the part first affected. It is remarkable that, while tuberculosis of the urinary apparatus is not uncommon in man, it seems to be very rare in women. Dr. Schramm says that only one case has been seen in the Dresden Hospital during the last twenty-two years. Perfectly healthy Fallopian tubes are seldom found, according to our author: and he quotes Hennig, who thinks that catarrh of the tubes is present in about a quarter of all cases (whether of dead bodies or of living women is not stated). The latter author also thinks that the tubes are the subject of catarrh oftener than any other part of the genital mucous membrane. Dr. Schramm finds that tuberculosis of the tubes originates in catarrh, and that it commonly begins in the ampulla. The walls become thickened, the tube filled with pus, and then caseation takes place, followed by ulceration of the mucous membrane. Miliary tubercles are not common; when present they are seen towards the abdominal end around the caseous knots. Histologically their structure is the same as that of tubercle in other parts. For a detailed account of this, as well as of the changes in the bloodvessels (which are also analogous to those elsewhere seen), we must refer our readers to Dr. Schramm's paper.—*Medical Times and Gazette*, January 20, 1883.

Successful Extirpation of the Kidney.—Dr. Reinhold Bruntzel reports a case in which the left kidney was removed from a woman aged 33, on account of a fibroid tumor, weighing 37¼ pounds, of the renal capsule. The abdomen was opened by an incision extending from the xiphoid process to the symphysis pubis. Recovery was complete in four weeks.—*Berliner klin. Woch.*, Dec. 4, 1882.

Retro-peritoneal Fibroma.—In a recent number of the *Zeit. für Geburtshülfe und Gynäkol.*, a case is recorded by Dr. Moricke, which he thinks, with reason, is unique, and we therefore briefly condense his account of it. The patient was twenty-four years old, had had two children, and was in fair general health. A firm, non-fluctuating tumor, as big as a man's head, rounded, and apparently loosely connected with the right side of the pelvis, was felt in the abdomen. This was diagnosed (erroneously, as it turned out) to be an ovarian tumor, and therefore an operation was undertaken. After the peritoneal cavity had been opened, the tumor was found to lie behind the mesentery. It was divided into two unequal parts by a furrow running from the upper and left part of it downwards and to the right. In this furrow lay a part of the ileum, the mesentery of which was spread over the tumor. The bowel was dissected off the new growth with the mesentery, which was cut through on each side, a little distance from the intestine. The dissection was one of great difficulty, the connection between tumor and ileum being very intimate. After the bowel had been freed, the flaps of mesentery raised with it were united over the part that had been attached to the tumor. At a portion of it the mesentery dissected up was not enough to surround the bowel without risk of stricture; and therefore, here, about half of the circumference of the intestine was left without any peritoneal coat. The tumor was then removed. It was fibrous in structure, and weighed about two pounds and a quarter. An ovary, which contained a small dermoid cyst, was also taken away. Slight pyrexia followed the operation, and lasted four weeks. The patient left her bed thirty-three days, and the hospital forty-two days, after the operation. Dr. Möricke remarks that the case is probably unique in the fact of a foot of intestine being deprived of its mesentery and left in the abdomen, and the patient nevertheless recovering.—*Medical Times and Gazette*, January 13, 1883.

Artificial Human Milk.—The method of preparation of artificial human milk as recommended and used by Prof. Frankland is as follows: Let one-third of a pint of new cow's milk stand twelve hours, then remove the cream, and add to it two-thirds of a pint of new milk as fresh from the cow as possible. To that one-third of a pint of blue (or skim) milk left after taking away the cream, add a piece of rennet (about one square inch in size) which, after it has served its purpose, can be taken out and used daily for a month or two, and allow the vessel holding the skim milk to be placed in warm water and there remain from five to fifteen minutes, until curdling is effected. Break up the curd repeatedly and carefully separate the *whole* of the whey, which should then be rapidly heated to boiling in a small tin pan, placed over a spirit or gas-lamp; during this heating a *further* quantity of casein (technically termed "fleetings") separates, and so straining after this, through fine muslin, is then required. Now dissolve one hundred and ten grains of powdered milk sugar in *hot whey*, and mix it with two-thirds of a pint of new milk as before prepared with extra cream. This gives us one pint of artificial human milk, which should be used *within twelve hours* after its preparation; all vessels and apparatus concerned in the manufacture being kept scrupulously clean.—*Physician and Surgeon*, January, 1883.

The Ophthalmic Lesions in General Paralysis.—M. Ch. Dutugue having examined the eyes of a large number of general paralytics, is led to draw the following conclusions:

In the first stage of general paralysis there is always irregularity of the pupils, papillary congestion, and varicose dilatation of the retinal arteries and veins.

In the second stage, the disorders are more advanced, with the addition of marked papillary and peripapillary œdema. The disk is often obscured, or even masked, by œdematous swelling, whose thickness is directly proportionate to the duration of the disease.

In the last stage, which terminates in death, the papilla is small, flat, and gray in color; the vessels which normally give it a pink tint having disappeared from the optic atrophy. To this atrophy, atrophy of the choroid, retinal hemorrhages, and granulations of the retina and choroid, are also to be added.—*L'Encéphale*, January, 1883.

The Excretion of Lime Salts in Phthisis.—This subject, which possesses clinical as well as pathological interest, inasmuch as it bears upon treatment, has once more been investigated by Prof. Senator, of Berlin (*Centralblatt f. die med. Wiss.*, 1883, page 11). It is no new observation that the amount of lime in the urine is increased in phthisis, but Schetelig had recently questioned the correctness of the conclusion. Both relatively and absolutely, however, the calcareous salts appear to increase in the urine during tuberculosis. There are very wide limits within which the amount of this excretion varies in health, viz., from .081 to .77 grammes in twenty-four hours. Still, this maximum, even, is exceeded in phthisis; and the continuous observation of an individual over a lengthened period also demonstrates a positive increase. The source of the lime salts cannot be found in the food, neither can it be referred to the wasting of the lungs, for these organs actually show an increase, and not a diminution, of their calcareous constituents when tuberculous. Senator suggests that the bones are to be credited with the excessive discharge, inasmuch as they manifestly waste in phthisis; the yellow marrow becoming red, and the lime salts being very probably set free in the process.—*Medical Times and Gazette*, January 20, 1883.

Vertigo in Tabes.—Drs. Marie and Walton believe that vertigo, closely resembling that of Ménière's disease, is of more frequent occurrence in tabes than is generally believed. The occurrence of vertigo in such cases usually coincides with the appearance of the early symptoms of tabes. The vertigo cannot be attributed to general atrophy of the auditory nerve, as its auditive function is preserved unimpaired, but may probably be attributed to lesion of certain fibres of the auditory nerve distributed to the semicircular canals, the so-called nerves of space.—*Rev. de Médecine*, Jan. 10, 1883.

The Bacillus Tuberculosis.—We learn from the *Wiener Med. Woch.*, No. 51, that Prof. Balogh, speaking recently before the Royal Medical Society of Buda-Pesth, stated that he had detected, in the marshes surrounding Buda-Pesth, a bacterium which behaves very like the bacillus of tubercle, but which he appears not to regard as such. He contends that neither the form nor the staining with dyes is sufficient to distinguish the varieties of Schizomycetes (fission-fungi). Experiments were conducted in which animals were allowed to inhale the fission-fungi of the marsh, with the result that, on post-mortem examination, little nodular growths were found in the lungs, heart, and kidneys; in the nodules the fungi were found in various stages of development, and the rod shapes stained with methylin-blue and vesuvin, just as do the bacilli of tubercle. Inoculation with bacteria from scarlatinal urine, and from ordinary sputa of bronchitis, gave rise to similar nodular growths which were not considered to be "tubercle." Prof. Koryanyi mentioned a case of a phthisical patient suffering from syphilitic lupus, which had improved under the use of iodide of potassium. In the sputa of this case, which was regarded as one of pulmonary syphilis, the bacillus of Koch was detected; hence Koryanyi holds that the presence of this bacillus is not a sure sign of "tuberculosis." We know of no more difficult questions than those raised by such observations. They seem always capable of more than one interpretation. It is possible that the bacillus found in the fens is identical with that supposed to be the cause of tuberculosis. Again, the notion that morphological appearances are not enough to split the group of the fission-fungi into varieties, has been upheld by eminent botanists. The remarks above reported raise again also the difficult question as to what is to be called tubercle. We may repeat here what we have elsewhere said, that various causes may give rise to products which to our senses are similar and indistinguishable.—*Medical Times and Gazette*, January 6, 1883.

New Operation for Total Extirpation of the Tongue.—Dr. Giovanni Fiorani has employed with success the following procedure in extirpating the tongue. The patient being seated on a chair in the upright position, with the head well extended and supported on the breast of an assistant, a vertical incision, one centimetre in length, and simply passing through the skin and cellular tissue, is made in the median line of the sub-hyoid region. The operator then introduces the index-finger of the left hand into the patient's mouth and passes it down into the left lateral furrow as near to the hyoid bone as possible. A trocar is then passed into the pharynx through the incision in the skin, and the loop of a doubled wire then passed through the canula: a thread is then passed through this loop and drawn out through the canula so that its ends remain in the mouth and the loop lies outside of the wound in the neck.

A similar procedure is then practised on the right side of the neck, and the free ends of the thread passing through the left side are then drawn out on the right side.

The thread is then replaced by a rubber cord 80 centimetres long and 4 millimetres thick, which is placed in position by passing it through the loop of the thread, and then drawing the ends of the thread out through the wound.

One loop of the double elastic ligature is then passed forward over the tip of the tongue, so that it lies under the tongue on the floor of the mouth and the ends are then tightened and knotted in front of the neck.

There is very slight pain produced during the operation, and the pain produced on tightening the ligatures only lasts a few minutes. Inflammatory reaction may be subdued with ice. On the third day the tongue becomes gangrenous; infection may be prevented by packing the mouth with iodoform gauze. The tongue, which should be secured by a thread passed through its tip, separates on the tenth or eleventh day.—*Rev. de Chirurgie*, January 10, 1883.

Pasteur's Researches.—A letter was read at a recent meeting of the Académie des Sciences from M. Pasteur, giving an account of his progress in some researches in which he is at present engaged in the district of Vaucluse. He has gone there to investigate a disease of pigs, which, in one valley of the Rhone, has recently been fatal to 20,000. The disease is called "le rouge des porcs;" and M. Pasteur announces that he has discovered its cause to be a very minute organism, which in point of size resembles that of chicken cholera. It differs, however, in its physiological properties, since it has no action on fowls, but it is fatal to rabbits and pigs, especially to white pigs. M. Pasteur has convinced himself, by experiments, that one attack affords protection against another, and he has succeeded in inoculating pigs with organisms which have been weakened by culture, and in thus rendering these animals insusceptible.—*Lancet*, December 16, 1882.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, FEBRUARY 17, 1883.

THE JOHNS HOPKINS HOSPITAL.

WE have had for some time upon our table a number of cuttings from Baltimore newspapers of last year, relating to the proposed opening of the Johns Hopkins Hospital, and the moving of the University of the same name from its present quarters near the centre of the city to a point in the suburbs. It would seem that there has been some difference of opinion among the trustees as to the time when the Hospital should be opened for the reception of patients, and that two of the trustees, Mr. John W. Garrett and Dr. Alan P. Smith, presented a report on the subject, in which it was advised that the Hospital should be opened in September, 1883, with ward accommodation for fifty-six patients, the dispensary, amphitheatre, and apothecaries' building; the reasons given being that the city is in want of gratuitous hospital accommodation, and that the University desires to organize its medical department as soon as possible to meet the demands which are made upon it, and that it cannot do this until the hospital is ready to furnish opportunities for clinical instruction. On the other hand, the majority of the trustees thought it better to wait until accommodation for at least one hundred and twenty-five patients was provided, that there was no urgent demand for hospital accommodation for the sick poor of Baltimore, and that the University would be rather glad than otherwise if the organization of its medical department was postponed for two or three years, as it has plenty of work on hand. The result was a decision that the Hospital should be opened if possible in the fall of 1885, and as the majority of the trustees of the Hospital are also trustees in the University, we presume that this is equivalent to a decision that the opening of the medical department of the University will be postponed to the same time.

Having recently had occasion to visit Baltimore, we made use of the opportunity to visit the hospital grounds and see what progress had been made. The hospital is located in East Baltimore near the top of the side of a hill which faces the city to the west, of which it commands an excellent view. The following buildings have been placed under roof, viz., the administration building, two pay wards, one octagon ward, three common wards, one isolating ward, kitchen, nurses' home, laundry, autopsy building, dispensary, and amphitheatre. The connecting corridors have not been constructed, nor the bath house, but with these exceptions the external work on all the buildings which it is proposed to erect at the present time seems to be finished. Ultimately, another octagon ward, three common wards, and one isolating ward are to be built on the south side of the lot, corresponding to those already erected on the north.

The buildings are of brick, with trimmings of a peculiar dark-blue fine-grained stone which has an excellent effect, and the materials and workmanship are of the best quality It is not our purpose to discuss the merits of the plan adopted, or to describe in detail the several buildings, since, even if we had all the data, it would be impossible to give an idea of the arrangements without the use of plates, which cannot be given here, and we can only notice briefly those features of the hospital which are more especially intended for educational and scientific work, and through which it is brought into immediate relations with the University. The most peculiar of these, and the one which seems most likely to have a strong influence on the plan of medical education to be adopted, is the provision in the administration building for lodging some thirty or forty students, the design being that the graduating class shall reside in the hospital during the last year of the course, which is to be devoted mainly to clinical work. The rooms for this purpose occupy the whole third story of the administration building, are large, airy, light, and well heated and ventilated, and are amply provided with bath-rooms, etc. On the lower floor is a library and reading-room for the students, and in an annex a handsome dining-room looking out at the end upon the central garden.

The building designated in the above list as the autopsy building, is situated on the north-east corner of the lot, which is its highest point, and diagonally across the street from grounds belonging to the University, and upon which it is proposed to erect the buildings for the medical school. This autopsy

building is really a pathological institute, or laboratory, containing a room for the preservation of the dead, a room for meeting of friends, etc.; a small amphitheatre, the arrangements for the ventilation of which are very good; two large rooms facing the north for microscope work and pathological investigations; rooms for photo-micrographic work, etc. This building is entirely detached from all others, and its arrangement appears to be very convenient and satisfactory.

The dispensary and amphitheatre are two large buildings located in the middle of the north side of the grounds in convenient proximity to the proposed medical school. Each building contains a large central room about fifty feet square, which, in the dispensary, is the reception and waiting-room for patients, and is surrounded with smaller rooms intended for the examination of patients by the clinical teachers.

In the amphitheatre the large room has seats for about two hundred and fifty students, and the smaller rooms adjoining are for waiting-rooms, the reception of accident cases, etc.

The two buildings are connected by a short covered way which allows of the free passage of air between them. The amphitheatre is lighted by a skylight, and by north windows behind the seats. A small dark-room is connected with it for the use of a photographer, so that a photograph can be readily taken of any case of interest. A corridor is to connect the amphitheatre with the basement of one of the wards.

A large amount of work remains to be done on this hospital, and as building operations must be restricted to the available income, which is about $130,000 per annum, it would require between four and five years to complete all the buildings and their connections, with the necessary heating apparatus and machinery. There can be little doubt that the trustees have acted wisely in deciding not to open the hospital before 1885. Even then they will not have had sufficient funds to finish all the buildings; and since the greater part of the income will be required to meet running expenses as soon as the hospital is opened, their building operations will drag on for ten years to come.

No doubt there is a demand for the medical department of the University, and the sooner it can be established the better; but this is to be taken with the proviso that it is organized on a proper basis. It is to the interest of the University that the hospital shall be as complete as possible, and be able to furnish the most ample clinical facilities.

So far as we can learn, the University authorities have not yet given the subject of their medical department much consideration. At all events, they have decided nothing; but the time is not far off when they should be giving the matter very careful attention.

We shall return to this subject hereafter. Meanwhile, we can say with confidence that if the medical school is as carefully planned, and as thoroughly worked out as the hospital has thus far been, it will be a great success.

ANOTHER DEATH FROM CHLOROFORM.

THE frequency of these announcements, surely, demands that the organs of professional opinion utter some authoritative mandate as to the use of a safer anæsthetic. If ether is, as we have abundant reason to believe, far safer than chloroform, ought there be longer delayed some authoritative expression founded on the general verdict of the medical profession, or a legislative enactment, to prevent the use of the more dangerous agent, unless the conditions requiring it are exceptional?

The last example affords capital illustration of several points which have, from time to time, been set forth in these columns. The cardiac failure induced by the first impression of nearly pure chloroform vapor; the administration of the anæsthetic by a method which ensures the exclusion of air from the first portion of vapor inhaled; and the omission of an expedient which we have reason to believe, if rightly timed, prevents many of the accidents occurring. It may be well to briefly recapitulate these several points, taking the example now before our readers in illustration.

Dr. Michael arranged all the details connected with the administration of the anæsthetic very carefully and prudently, in accordance with the general practice. There are several points, however, sanctioned by usage, which appear to us to demand criticism. The administration of a large dose of whiskey before beginning the inhalation, it seems to us, is not based on a proper knowledge of the action of this agent. *Large doses* of alcohol depress the heart's action, and lower the temperature. The subcutaneous injection of morphia, as originally proposed by Bernard, and afterwards by Nussbaum, and in this country advocated by the late Dr. Wm. Warren Greene, and by Dr. J. C. Reeve, of Dayton, is an expedient of the utmost value, both to facilitate the inhalation, and to prevent cardiac failure. Morphia and atropia are now used together, with distinct advantage. If administered before beginning the inhalation, the cardiac failure which so often occurs when the first impression is made on the motor ganglia will be largely prevented.

In this fatal case, we hear again that a towel cone was the inhaler used. A quantity of chloroform is poured into the cone, the application is made over the mouth and nose, and sufficient air is supposed

to enter from the open top of the cone. Now, as the vapor density of chloroform is so much greater than atmospheric air, it is obvious, having regard to the law of diffusion of gases, that for the first few minutes of the inhalation the patient receives almost pure chloroform vapor. In a great majority of cases, as Dr. Michael well observes, it is the first portion of chloroform inhaled that paralyzes the heart. The reason for this—apart from any question of cardiac disease—is that a concentrated vapor first passes into the lungs. In the administration of chloroform it is indispensable to secure a proper admixture of air, and if this is not accomplished, any method of inhalation becomes dangerous.

We have so recently discussed these questions connected with chloroform administration, that we forbear from further comment. We cannot, however, conclude without expressing our conviction that with our existing knowledge of anæsthetics, no one is justified in using chloroform as the anæsthetic when ether can be substituted.

HYGIENE OF WRITING IN SCHOOLS.

AN interesting paper has recently been published by Berlin, on the influence upon the eyes and the spine of school children which so simple a matter as the position of the copy-book, in writing, may exert. It is based upon the report of a commission appointed to investigate the effect of slanting writing in the schools of Würtemberg. It was found that the attitude assumed by the child in writing was determined by the position of the book; and optical and physiological reasons are given for this fact. In writing, or drawing with straight lines, the visual axes move, by perference, in two general directions, vertical and horizontal, because in looking upwards or downwards, or to either side, their paths are straight, while in diagonal movements they describe a curve.

Three hundred and seventy-one children were carefully studied while in the act of writing, and it was discovered that about 93 per cent. of them made the down-strokes in a direction nearly at right angles with that of the base line, *i.e.*, the line connecting the centres of rotation of the two eyes and forming a triangle with the visual axis in convergence. This is done with least strain when the copy-book is tilted toward the left; when the child is compelled to write with the book parallel to the edge of the desk, he brings the base line perpendicular to the down-strokes by turning his head towards the right and twisting his spine. This contortion brings the eyes nearer to the page, and the left eye nearer to it than the right.

In a discussion of this subject at the meeting of the Ophthalmological Society, at Heidelberg, Laqueur and Manz favored the slanting system of writing with an oblique position of the book, on the ground that it throws the work more on the flexor muscles of the forearm, which are naturally stronger than the extensors, and Berlin dwelt upon the fact that this system admits of greater rapidity of execution.

A practical point in ocular hygiene is the material provided for children to write upon. The common slate has incurred the disapproval of ophthalmic surgeons, and Horner strongly advised that it should be banished from the schools. As its surface is shiny and presents an insufficient contrast with the letters, it necessitates a nearer approach of the eyes, and consequent excessive accommodation and convergence—the most important factors in the development of myopia. Cohn has, therefore, caused artificial white slates and special pencils to be manufactured, which offer the conveniences which have given the old articles universal currency among former generations of children without their hygienic defects.

KAIRINE.

IN the attempts to produce quinine, synthetically, now making in Germany, various new products which have been employed medicinally, have been brought forward. Although a true quinine has not thus far been accomplished, a near approximation to it has been made. Quinoline or chinoline is one of these. Recently, however, DR. FISCHER (*Berliner klin. Wochen.*, No. 45, 1882) has produced a phenol, to which he has applied the term *kairine* for short, although its true name is *oxy-quinoline—methyl-hydride* in chemical language. The salt which has been employed medicinally is the hydrochlorate. It has no irritant qualities, and in the normal state causes no obvious disturbance. All the members of the phenol group are antiseptic and antipyretic. The antipyretic stands in a nearly constant ratio to the antiseptic action. This fact is strongly suggestive, for if the power to destroy the organisms of disease or septic ferments, is the source of the antipyretic action, it is in a high degree probable that the febrile action is a consequence of the multiplication and growth of germs or ferments. The action of antiseptics lends support to the parasitic or zymotic theory of the infectious diseases.

Besides kairine, there have been introduced kairoline, and in addition to resorcin, quinoline and pyrocatechin, all members of the phenol group, and all possessed of antiseptic and antipyretic effects. We are confident that the time is not distant, when that most valuable of all antiseptics and antipyretics—quinine—will be produced in the laboratory of the chemist.

THE ALKALOIDS OF THE HUMAN BODY.

LIKE certain plants, the human body has the power to produce alkaloids. Our readers have been placed in possession of the facts regarding *ptomaines*, those alkaloidal substances formed in the course of putrefactive decomposition. These ptomaines, like the alkaloids recently recovered from the urine in infectious diseases, are vegetable in origin. Beside these, recent researches have demonstrated the existence of similar alkaloids in the bodies of normal, living persons, formed in the digestive tube, and apparently elaborated, says Bouchard, by vegetable organisms—agents of intestinal putrefaction. The alkaloids found in normal urine represent a part of those produced in the intestines; they are absorbed and subsequently eliminated by the kidneys. It has been found that those disorders increasing intestinal putrefactive decomposition, augment the quantity of the alkaloids found in the urine. It is considered probable by Bouchard that the alkaloids of certain infectious maladies may have their origin in microbes contained in the tissues or fluids, as it seems established that in typhoid fever a portion of the urinary alkaloids originate in the intestinal canal.

It is obvious that these researches open up great possibilities in respect to the study of the pathogeny of infectious diseases in general. For example, the supposed typhoid poison may be developed by a certain form of fermentation taking place in the intestinal canal. Clinical therapeutics contributes to the number of these probabilities. Such a theory, or rather the new fact regarding the existence of a group of alkaloids, is supported by the results of the so-called "specific medication." The calomel purgative treatment of the first week, the iodine method, and especially, the carbolic acid medication of the whole course of typhoid, indicate by the results obtained from them, the probability of some kind of intestinal fermentation producing the material which, by its action on the solids and tissues of the body, causes the objective phenomena of typhoid. That which is thus rendered probable for typhoid, may also, in some form, be regarded as causative of the various infectious diseases.

ARTIST DOCTORS.

IN a very interesting article on "American Etchers," in the *Century* for February, Mrs. Schuyler Van Rensselaer mentions with honor, among other American etchers, the name of Dr. Leroy Milton Yale, and gives a very creditable example of his work, which, we observe, was an August vacation study. Etching has been only a recreation with him, yet he was one of the most earnest founders and fosterers of the New York Etching Club. We wish that more of our profession would take up similar artistic or literary studies, not only as a recreation, but because they broaden the mind and soften the hard grind of daily work. Sir Henry Thompson is a notable instance of how a very busy London surgeon can achieve somewhat of fame with the brush. Mr. Seymour Haden is always to be first named among the etchers, of course, but his chief fame is as an artist rather than a surgeon.

So far as we know, Dr. John H. Packard is the only active member of our Philadelphia profession who has done much in art, and even his pencil and brush have not given us of late as much as we could wish.

URETHRAL INJECTIONS OF BROMIDE OF POTASSIUM

DR. CAMBILLARD, in his *Thèse de Paris*, for 1881, advocates the employment of a solution of potassic bromide to quiet chordee. Every one will admit, he truly says, that the painful erections called chordee are very difficult to relieve, and that the number of the remedies proposed is only equalled by their inefficiency. He has obtained uniformly good results from urethral injections of the following:

℞.—Aquæ, ... ℥ij.
Glycerini, ... ℥iij.
Potassii bromidi, ... ℥iss.
Tinct. opii, ... ℥j.—M.

Sig. Four injections of this quantity in twenty-four hours.

To prevent the nocturnal attacks, he insists that the last injection be practised just on retiring for the night. These injections cause almost no pain, and are very effective in relieving the distress.

THE College of Physicians of Philadelphia has just been made the recipient of the generous gift of $5,000, from its distinguished Fellow, Dr. S. Weir Mitchell, as an entertainment fund; the interest to be expended annually for the purpose implied. This selection of a purpose has been wisely made. Founded in 1787, the College of Physicians is at once the oldest, the wealthiest, and among the most select of the medical societies of the country; and it is as important that it should set an example of this kind as that the wealthy and influential citizens of a community should lead in its social life. The commodious rooms of the College afford ample space for entertaining a large number, and its magnificent library and valuable museum are important adjuncts for such a purpose. We predict that the impetus recently given to the activity of the College in the direction of clinical and scientific work, will be increased by this new movement, and that it will also stimulate the contribution of money required for the proposed enlargement of the building so as to accommodate it to the growing needs of the library and museum.

REVIEWS.

The Systematic Treatment of Nerve Prostration and Hysteria. By W. S. Playfair, M.D., F.R.C.P., Professor of Obstetric Medicine in King's College, etc. 12mo. pp. 92. London: Smith, Elder & Co., 1883.

The Same. 12mo. pp. 111. Philadelphia: Henry C. Lea's Son & Co., 1883.

In this attractive little volume Dr. Playfair has collected the two papers on the treatment of nerve prostration and hysteria, which he published in the *Lancet* in 1881, and his introduction to the discussion on the same subject at the late meeting of the British Medical Association. Dr. Playfair is a firm believer in the efficiency of Dr. Weir Mitchell's "rest cure" treatment in properly selected cases, and he cites some very striking examples of cure, which he has obtained under this method. Like Dr. Mitchell, he lays particular stress upon the necessity of isolation of the patient and her removal from unwholesome domestic surroundings, and he is satisfied that any relaxation of this rule will prove an absolute bar to success.

Although Dr. Mitchell, in the introduction to his little volume on *Fat and Blood*, very modestly disclaims any thought of "putting forth anything very remarkable or original" in his treatment of neurasthenia by rest, systematic feeding and passive exercise, nevertheless, we think that the merit of having introduced it as a method unquestionably belongs to him, and we regret to see that there has been a disposition in some quarters to deny this. On this point Dr. Playfair, we are happy to find, does full justice to Dr. Mitchell, as will be seen from the following extract: "I feel proud to say that, having carefully studied what has been written on the subject, I can nowhere find anything in the least approaching to the regular, systematic, and thorough attack on the disease here discussed.

"Certain parts of the treatment have been separately advised, and more or less successfully practised, as, for example, massage and electricity, without isolation, or isolation and judicious moral management alone. It is, in fact, the old story with regard to all new things. There is no discovery, from the steam engine down to chloroform, which cannot be shown to have been partially foreseen, and yet the claims of Watt and Simpson to originality remain practically uncontested. And so, if I may be permitted to compare small things with great, will it be with this. The whole matter was admirably summed up by Dr. Ross, of Manchester, in his remarks in the discussion I introduced at the meeting of the British Medical Association at Worcester, which I conceive to express the precise state of the case: 'Although Dr. Mitchell's treatment was not new in the sense that these recommendations were made for the first time, it was new in the sense that these recommendations were, for the first time, combined so as to form a complete scheme of treatment.'"

A Treatise on the Science and Practice of Medicine. By Alonzo B. Palmer, M.D., LL.D., Professor of Pathology and Practice of Medicine, and of Clinical Medicine in the University of Michigan, etc., etc. Vol. II. 8vo. pp. 866. New York: G. P. Putnam's Sons, 1882.

The second volume of Dr. Palmer's work is now offered to the profession. It claims in many places to represent, as does the preceding volume, the special indications of American practice. The author is, indeed, convinced that many methods of treatment so successful in Europe, are not suitable to our climate, our habits of life, and in fact, to our constitutions. Moreover, he has remarked that statistics abroad are based mainly upon the results of hospital treatment, or upon what is the direct outcome of consultant practice, and are not, as they should be, the matured judgments of close attendance day by day, from the beginning and in private practice of each individual case. In consequence of these facts, many phases of conducting cases which appear reasonable and judicious to our European brethren, are to us antiquated and irrational. The second volume of this extensive treatise is not unlike the first in the general characteristics. Many subjects are described and but few omitted which should be contained in a work on general practice. Some portions of the work are tolerably satisfactory in details, and particularly those which relate to affections of the respiratory tract. In his exposition of nervous diseases, the author betrays, we believe, a want of familiarity with their protean clinical aspects as well as with their minute morbid changes, which can but lessen the value and importance of his teaching. Here and there throughout this work, we encounter practical hints of considerable value in the management of cases, and certain therapeutic combinations recommended by the author are worthy of remembrance.

The pathological part of the second volume shows, we regret to say, rather the research of a gleaner in others' fields than that of one who has steadily worked upon a fruitful soil with the desire of making personal acquisition. The style throughout this volume is not invariably what is admirable, and occasionally we find the author betrayed into using expressions which are both lax and personal; such defects of writing should be remedied in another edition of the work. As a guide for students, we can scarcely recommend Dr. Palmer's work, since in those of at least two well-known American authors, we have works either of higher scope or more lucid exposition. To the general practitioner there are some paragraphs here and there which can be advantageously read and perhaps become the origin of well-considered practice.

A Study of the Tumors of the Bladder, with Original Contributions and Drawings. By Alex. W. Stein, M.D., Surgeon to Charity Hospital, Genito-urinary and Venereal Division. 8vo. pp. 94. New York: William Wood & Co., 1881.

This monograph opens with a valuable collection of one hundred and fifty-five cases of tumor of the bladder, and then furnishes an excellent description of the benign and malignant growths which have their origin in this organ.

The chapters following, devoted to the consideration of the symptoms, diagnosis, and treatment of vesical tumors, cannot fail to impart to the reader much valuable information upon this very interesting class of cases.

Upon the question of treatment, the author not only expresses himself decidedly in favor of early operative interference for the removal of benign tumors, but also thinks that in many cases of malignant growth this procedure offers a reasonable hope of temporary, if not of permanent, relief.

In this statement, we think, the author only expresses the sentiment of the profession at the present time, which look with growing favor upon operations for the removal of these growths; for the results of the various operations to accomplish this object, both in

cases of males as well as in those of females, have been sufficiently satisfactory to insure its position as a justifiable surgical procedure. Although exception might in some places be taken to the author's style, yet a perusal of this work cannot fail to waken a new instinct in, and give the reader a clearer idea of the diagnosis and management of this interesting, but distressing class of cases.

SOCIETY PROCEEDINGS.

MOTT MEDICAL CLUB, OF PITTSBURG.

Stated Meeting, January 8, 1883.

DR. WILLIAM WALLACE IN THE CHAIR.

DR. J. CHRIS. LANGE read a paper entitled

SOME CASES OF DIPHTHERIA TREATED BY MERCURIALS.

He said our knowledge of the action of mercury on the system may be defined, briefly, as follows: its effects are chiefly owing to a corrective influence on the quality of the circulating fluids, first—and, secondly, it is generative of more or less complete processes, antagonistic to, or substitutive of, diseased action or abnormal processes. Under its influence the secretions and exhalations are increased, the textures softened, morbid growths and deposits are removed, or their increase more or less perfectly hindered. Visceral and glandular enlargements diminish or disappear, phlegmonous inflammation of every kind is opposed, and in all inflammations hyperinosis is diminished, the red corpuscles are less inclined to aggregation, and the white ones to adhesiveness. The exudation of plastic lymph is limited, and, as a consequence, also the formation of false membranes. Further, mercury softens and destroys the tissues, impoverishes the blood, interferes with nutrition, and produces a condition of marasmus and cachexia.

In the consideration of the mercurial treatment of diphtheria—as in any other—the question arises: What do we desire to effect by the administration of the chosen remedy? The answer to this is that by its exhibition we desire to so modify it—the poison in the blood—and to so limit its pernicious action on the system, together with its product, that the patient may live during its continuance. It is proper to inquire, then, what are the events which, in diphtheria, threaten to terminate life; in other words, what are the causes of death, and also, what influence has mercury on them?

The six cases to be presented for consideration are the most unfavorable of a series of forty-three cases, treated by mercurials during the last two years. The other thirty-seven cases recovered, as they probably would have done under other reasonable treatment, as we have had, fortunately, no very malignant epidemic during this time. The six cases were such, as under other various plans of treatment formerly employed by me, almost invariably proved fatal.

The poison itself may be a cause of death; this may be so virulent, that life is incompatible with the blood that contains it, and the patient dies as soon as the unknown chemico-vital changes in the blood are sufficiently complete.

Case I.—E. S., female, aged 13 years, Coal Hill, South Side. First seen on the morning of February 12, 1882. Temperature 105°, pulse 140; extremities cool; had vomited once during the night, and complained of sore throat the day before, but had not seemed very sick. Membrane on tonsils; cervical glands enlarged, and cellular tissue infiltrated about the throat. She is restless and stupid; moans and tosses about in bed; she had passed a normal amount of urine, and had an evacuation of the bowels that morning; her abdomen was tympanitic. The next morning she had a collar of brawn; great tympanitis; congested conjunctivæ, and was comatose; she died at 2 P. M., that second day. I may mention her treatment, not as illustrative of either good or harm, for none could have controlled or even modified the action of the quantity or virulency of the poison she had received; it was 10 grains of calomel every hour, with ice to the throat, and stimulants.

Another cause of death, is the exudation of the membrane upon the mucous surface of the larynx, trachea, or both; with the tumefaction of the tissues beneath and about it. What can be expected of the mercurial treatment in this condition? It is freely asserted here in our city, that benefits impossible to be attained by other methods of treatment, are its results; and the cases related below would seem to agree with the assertion. If it be true that the membrane accompanying the laryngeal inflammation, and the tumefaction of the underlying structures be only in the least diminished, this would be of the greatest importance in this particular situation of the inflammation; and is it unreasonable to grant—with the knowledge that mercury opposes hyperinosis, and limits the exudation of coagulable lymph—that it may also do this in diphtheria, thus limiting the size and thickness of the membrane, and moderating the inflammation? If the obstruction of the air passage be sufficient to give rise to urgent symptoms of asphyxia, surgical measures will remove the patient from this danger to life, and expose him to another, to be mentioned further on. An interesting question is, what determines the inflammation to the larynx in one patient, and not in another? It is not the intensity of inflammation, nor the duration of the disease; for we see in one patient, the faucial membrane reproduced one or more times, the larynx remaining exempt; and again, the larynx involved before the detachment of the first faucial membrane, or, if true croup be diphtheritic, without any faucial membrane. With the fact at hand, that a certain individual will, from cold or exposure, take a tonsillitis, and another a laryngitis, and yet another a coryza, it is fair to assume that the surface selected by a diphtheritic deposit is determined by the same force.

On the 13th day of April, 1881, I was called to attend a girl seven years old, living on Stanton Avenue. She had had faucial diphtheria five days, the membrane was now being detached, and she had croup since the day before. She had been treated by a homœopath, who had left the case with the statement that she could not live ten hours. I gave her ten grains of calomel every two hours for twenty-four hours. On the 14th, the following day, dyspnœa was extreme, the extremities cool and blue, as were the lips; spasm of the glottis was frequent, and left her wet, cold, and blue. The treatment was continued until the morning of the 15th, when a slighter degree of dyspnœa being perceptible, the quantity was reduced to five grains. During the forty-eight hours in which she had taken four drachms of calomel, she had three stools. She continued to improve, and, on the 19th, the sixth day, her larynx was clear and her voice restored, when treatment ceased. She was slightly ptyalized; she had taken one ounce of calomel. After the first forty-eight hours her bowels had not moved; she had no sequelæ. On September 11, 1882, this same patient was again attacked, she was now eight years and five months old. Temperature 104½°; pulse 120; membrane on both tonsils and posterior pharyngeal wall; ten grains of calomel were given every two hours for forty-eight hours; bowels moved once. On the 13th, the third day, temperature 102°; pulse 120. From 13th to 17th, five grains every two hours.

From 11th to 17th she took one ounce. Bowels not having moved since 12th, a spoonful of castor oil was given, and the mercurial continued. This patient would take absolutely no nourishment of any description, and very little water. 18th, membrane almost gone from fauces; slept all night except when disturbed to take her powders; had two evacuations of the bowels, and took the first spoonful of nourishment this morning. 19th, temperature 102°; pulse 130; a new membrane forming on fauces; ⅛ grain corrosive sublimate every two hours; calomel discontinued. 20th, temperature 101°; pulse 140; membrane larger and thicker than the first; patient exhausted; will not take spirits, nor meat extract, nor quinine, nor milk. Nasal and laryngeal mucous membranes free from the inflammation, Has always passed urine. Died on the 21st, of exhaustion.

This patient took absolutely no nourishment from the onset of the disease, and emaciated remarkably during the first few days. The history of these two attacks of this patient demonstrates, 1st. Either that the mercury exhibited early in the second attack prevented a laryngitis, which occurred during the first attack, before she had had mercury, or that a laryngeal inflammation, in diphtheria, is entirely accidental, and not determined by any idiosyncrasy as is the simple inflammation of the larynx, tonsils, or Schneiderian membrane, from cold or exposure; and next, that mercury is not a specific for diphtheria. This patient certainly had a sufficiency of it; one ounce and two drachms of calomel, and two grains of the bichloride; and the formation of a second membrane demonstrates that it entirely failed to control or modify the virulency of the poison. And, thirdly, in this aspect of the matter, namely, that the disease was not favorably influenced by the treatment, it is a justifiable conclusion that the treatment she received during her first attack may have had nothing to do with her recovery. This patient died of exhaustion; there were no complications, nor was there any other cause of death. I was at the bedside when she died. She was conscious, and asked for water; to give her this I raised her up, when her heart failed and I laid her down dead. It is proper to inquire how much, if any, of the direct cause of her death, exhaustion, was contributed by her treatment; this will be spoken of further on.

Another cause of death is uræmic poisoning; this is a rather rare occurrence in diphtheria, as rare as albuminuria is frequent, and this latter is rather a matter of scientific interest than of practical importance. It is not an unfavorable prognostic sign, and requires no special treatment.

Another cause of death, also rare, is said to be "blood poisoning"—secondary blood poisoning, from absorption from the affected surface. When in a certain patient, about to die, this absorption is said to have taken place, its signs and symptoms are so indefinite and mysterious, and so complicated with the signs and symptoms of the primary poisoning, that it must be confessed a gratuitous assumption; it is not indicated by the signs and symptoms of septic or purulent absorption in other conditions.

Another cause of death is when the membrane forms in the nares. This nasal diphtheria, especially when preceded by a deposit on the fauces, is very fatal. This is sometimes accredited to the, I think, erroneous assumption that the inspired air, passing over the affected surface to the lungs, is impregnated with the exhalations, and, perhaps, the special poison of this surface, or that there being so much surface in this situation (anterior and posterior nares), the membrane becomes correspondingly large, whereas, the truth is, these patients do not breathe through the nose—the nares are effectually closed, except to forced efforts; and there is no evidence to justify the belief that the soil in the nares is more favorable to the growth of the membrane than that in the pharynx or larynx; indeed, from its rarer occurrence here, it may be asserted to be less so. What so largely contributes to the exhaustion is, it seems to me, that these patients must keep their mouths open; and with their mouths open they are never in a state of rest, but in a state of continuous muscular action; this constantly disturbs the patient during sleep; he falls asleep, his mouth closes, want of breath wakes him up, he cannot open his mouth while asleep, and this recurs every few minutes; hence, I have found it beneficial to insert between the teeth a pencil, or other suitable object, that his muscles may relax, and he may still breathe. This closure of the nares is also an additional impediment to his swallowing. The air compressed, during the act of swallowing, exerts a painful pressure on the pharynx and posterior nares when it cannot escape through them. Again, when the nares are closed, the blood retains more carbonic acid and obtains less oxygen, it requires an effort to breathe, and an effort to breathe, under any circumstances, implies imperfect oxygenation of the blood; a person running breathes with an effort, because of this; a person with pulmonary emphysema might breathe faster, and so perfectly oxygenate his blood, but as this would be a voluntary act, and would require an effort, he does not do it—cannot do it long—and so exists with the least amount of oxygen, and the greatest amount of carbonic acid, compatible with his particular status of health; and the same is true of the patient with nasal diphtheria. These seem to me the principal circumstances that contribute to the fatality of nasal diphtheria.

On the 26th of April, 1882, I saw a boy, 4 years old, and on the next day a girl, 7 years old, living in the same tenement—98 Mulberry Street—both with nasal diphtheria, following the faucial membrane by a day or two, In the 7-year-old the membrane was visible in the anterior nares; in the 4-year-old it was not so. In both cases the nostrils were filled with muco-pus, which freely dribbled down upon the mouth unless cleansed away. They both lay with open mouths and red conjunctivæ, and it was with great difficulty any nourishment could be administered; they were both stupid; ten grains of calomel were given every two hours for four days, this being one ounce for each. A small stick wrapped with canton flannel was placed between the teeth. The 4-year-old had but one or two stools daily, but the 7-year-old was violently purged during the first twenty-four hours; she was accordingly given ten grains of bismuth with ten drops of U. S. P. solution of morphia after each powder of calomel; this was discontinued on the third day, as she was no longer purged. On the sixth day they were both rather better; the 4-year-old now refused to take his powder, and was given one-eighth of a grain of corrosive sublimate every three hours, instead of five grains of calomel which the 7-year-old was still taking. They continued to improve from day to day, and on the 4th day of May the nares of both were clear. They were both slightly ptyalized—but very slightly; they got no treatment for this. I desired in their cases to use the mercurials only and energetically, and succeeded. They received no iron, quinine, potassic chlorate, nor stimulants. I ceased attendance on the 7th of May—the twelfth day. The girl had no sequelæ. On the 15th I was again called to see the boy—the 4-year-old—who had, not paralysis, but contracture of the flexors of the extremities. His gastrocnemii were so contracted that his toes were on a line with his legs, his forearms were strongly flexed on his arms, while his fingers were clamped into the palms of his hands, which were flexed on the wrist and which he could not

use. It was with difficulty that his hands could be opened and his forearms extended. Believing this to be a temporary condition only, I gave him no treatment for it, and it gradually disappeared during the next ten days. These children are both well at this writing. I may mention that, as a matter of cleanliness, a weak solution of carbolic acid was used to wash out the nares, by means of a Davidson syringe. During the nine days of treatment these children took—the 4-year-old, one ounce and two drachms of calomel and two and a half grains of the bichloride; the 7-year-old, one ounce and five drachms of calomel.

As illustrative of the tolerance of mercury in diphtheria, the following case is of interest:

Babe, 11 months old, was brought to my office on the twenty-second day of August, 1882, with a diphtheritic membrane on its fauces, and the usual signs and symptoms of laryngitis. It was voiceless, had dyspnœa, cool extremities, and a hot head, with spasm of the glottis on coughing; it had been sick three days. It took five grains of calomel every hour. After a few days it improved; it nursed better; its dyspnœa diminished; it gained in strength, and soon began to expel membrane; its bowels were never moved more than two or three times in twenty-four hours; and its voice returned. It took this quantity of calomel seven days and twelve hours, making one ounce and seven drachms; and it sat upon its mother's arms, looking cheerfully around the room; no evil effect of the mercurial was visible; it died on the ninth day, from—as its mother says—a choking spell. A piece of membrane, from its trachea, probably—for its voice was restored—was so lodged by a cough as to occlude the air passage. There is no doubt in my mind that this accident alone caused its death. It was comparatively well, coughed, got blue, and was dead before I could get there—nine doors from my office. It will be admitted that this case may be counted as a cure of diphtheritic croup; and that the mercurial could not have been, in any manner, causative of nor contributive to its death.

The deleterious effects of mercury were not visible in any of these cases, not excepting the eight year old girl, who died of exhaustion during her second attack. I believe the mercury contributed nothing to this exhaustion; 1st, because it did not purge her; next, because there is no evidence to prove that mercury impoverishes the blood, interferes with nutrition, or produces a state of marasmus or cachexia, except it be given for a long period of time, as is done for chronic disease; and 3dly, when it is remembered that our experience of cases, where, on the eleventh day a new faucial membrane is completed, and that will not feed, cases that have not been treated by mercury, but by any method you please, when it is remembered that our experience of such cases is always disastrous—it is not warranted by the facts to conclude that her treatment was in any degree contributive to the death of this girl.

The quantity of the medicine administered to these patients may have been excessive, not for their tolerance of it, but because it seems impossible it should be absorbed; this may be true—I do not pretend to know, and I do not give so much in fair cases, *i. e.*, cases such as have recovered under other plans of treatment I formerly employed. I see no reason to give an infant much less than a child of 4 or 6 years, because, the younger the child the less likely it is to be purged. I prefer the mild chloride, because pouring it upon the fauces may have a local effect, as it has in other conditions. The bichloride is more easily taken. I have four cases in the same family under this treatment at the present writing; they are what I have designated as fair cases, cases that under the treatment I formerly employed, would probably recover—they are 4, 6, 9, and 11 years old respectively, and are taking five grains every three hours, with a grain of quinine thrice daily. They will continue this until they have taken two, three, or four drachms, or until their membranes are gone, or going, or until their gums show the effects of the remedy. These four cases are not included in the series of forty-three cases. Sometimes I give four drachms rapidly and then change to quinine, or quinine and the tincture of iron, with or without stimulants. The salivation that occurred in some cases, has never been of any gravity; they complained of sore mouth, but it has not been bad enough to prevent eating or nursing. The six cases related to you were, as I have said, such as under all other methods of treatment, I have been accustomed to see die; for this reason they received this remedy in such quantity.

Exhaustion is the direct cause of death, in the great majority of those who die of diphtheria. It is to this danger that the surgeon exposes the patient, when, by a tracheotomy, he rescues him from that more immediate one, asphyxia. It is to exhaustion, also, that the necessarily perturbating treatment, the induction of vicarious elimination by the bowels and skin, contributes—in uraemia; and the conditions attending nasal diphtheria, before enumerated, are also conducive to exhaustion. It is therefore necessary, to any successful treatment, to guard against the increase of exhaustion, by every possible means; food, medication, stimulants, etc., none of which need be excluded by the administration of mercury.

Although it may appear incongruous to use, at one and the same time, a supporting treatment and mercury—a sedative and antiphlogistic—this latter may become the most important factor in the restorative process; as an instance of this, drastic purgatives, generally so debilitating, are, for a patient almost moribund with dropsy and uræmia, the most powerful restoratives. It may be, that in an analogous manner, or in some unknown manner, mercury is tolerated, as well in diphtheria, as purgation in dropsy; future experience only can demonstrate if this be true, and whether it has a curative or modifying influence on the disease which outweighs its possibly injurious effects, together with its best form of administration and its proper dose.

Dr. McCann said that a tolerably extensive experience with diphtheria, extending over a period of eighteen years, enabled him to confirm several of Dr. Langes's observations in regard to the calomel treatment. First, that calomel given in hourly doses of from gr. iij to gr. vj to children under three years old does not purge excessively, if it purges at all; that it does not prostrate even when its use is continued during twenty-four, thirty-six, or forty-eight hours; that it does not salivate; that it arrests the spread of the exudation, and causes the membrane to separate at an earlier period than do the ordinary methods of treatment; that convalescence begins earlier, and progresses more rapidly and with fewer complications; and that older children and adults bear proportionately larger doses of this remedy. His personal experience with calomel in the treatment of diphtheria leads him to believe that in the vast majority of cases, if taken early, within twenty-four or thirty-six hours after the onset, the disease is not difficult to control. It may look like "heavy dosing" to administer calomel to a child in the doses Dr. Lange has recommended, especially in the light of modern teaching, but, in his judgment, it is not so "horrible" as to sit by the bedside of a child that is slowly choking to death with diphtheritic croup; nor so horrible as to submit that child to tracheotomy in the too often futile hope that life may be saved by the operation; nor half so horri-

ble as to look in utter helplessness and despair at the livid face and swollen neck and gangrenous throat, and occluded ichor-weeping nostrils of the victim as it drifts hopelessly to death. He had tried this remedy faithfully in diphtheria, not once nor twenty times, but in more than a hundred as bad cases as he had ever seen, and it had not disappointed him where there was a reasonable hope. He had relied upon it in his own family, and when his own children seemed stricken with death. It did not fail, did not disappoint him then; nor does it ever, when given fearlessly, and persevered with to the end.

DR. MURDOCH said that he desired to enter his most earnest protest against this wholesale use of calomel in the treatment of diphtheria. His experience in its use is indeed but limited. It extends to but two cases, which were under the care of Dr. Reiter, who may justly be called the father of this practice. Of course he could not say that these two cases would have recovered under a supporting treatment, but he knows that they died promptly under the calomel treatment, which in his opinion is an exhausting treatment.

He regarded diphtheria as primarily a local disease, which rapidly becomes constitutional. The local treatment should be by antiseptics, and such means as dissolve the false membrane, viz., lime water and carbolic acid. The constitutional treatment should be by germicides, such as the tincture of iron, etc. But more important than all is the maintenance of the vital powers by alcoholic stimulants and proper diet until nature is able to eliminate the poison.

This, in brief, is the treatment advocated by Morell Mackenzie, Jacobi, and, in fact, by all the more recent authorities who have studied the subject. His success by this plan of treatment has been quite satisfactory. The use of calomel in such doses as are recommended by Dr. Lange, in a disease so exhausting as diphtheria, seems to him a step backwards. He can only explain the tolerance of calomel in diphtheria on the supposition that for some reason it passes through the system unchanged. Surely, if this were not the case, no patient could survive such enormous doses. He has great respect for the opinions of Dr. Lange, and the gentlemen who differ with him, as he had also for the opinion of Dr. Reiter, the originator of this mode of treating diphtheria, but he cannot permit this to weigh against his own experience.

DR. EMMERLING said the mercurial treatment of diphtheria, especially with large doses of calomel, is not new, but was practised in 1821 with varying results by Bretonneau. Much mischief generally ensued, when the remedy was administered until salivation, with the general effects, was produced. He has not employed calomel, but prefers and has frequently and with satisfactory results given corrosive sublimate (in dose of $\frac{1}{16}$ to $\frac{1}{32}$ of a grain every two or three hours, according to age), selecting for its employment the severer forms of diphtheria, those in which the old method of treatment gave very unsatisfactory results. He places great reliance on nourishing and stimulating treatment from the onset.

DR. RANKIN said that he disagreed with Dr. Lange. He has treated a large number of cases of all forms of diphtheria, and has employed all methods of treatment. Diphtheria is an asthenic disease, requiring supporting, stimulating, and antiseptic treatment from the beginning. Dr. Lange has given us no positive theoretical principle whereon to base his treatment, and as other remedies have yielded better results, it becomes our duty to employ them. If mercury is not a positive antiseptic, it would be preferable to leave the disease to nature, as it defibrinates the blood. Mercury and bloodletting had their advocates years ago, but because of unfavorable results they have been almost entirely abandoned.

We have all observed cases of a mild form, which mildness may be due to the presence of a large amount of vital power, which successfully resists the effect of this poison. It is, perhaps, in this class of cases that the mercurial treatment proves successful. Before employing a remedy in a disease requiring energetic treatment, we should know why we use it, and what to expect from its use. It has never been proven that mercury is antagonistic to diphtheria. Comparing the experience of prominent observers with his own, he is led to conclude that diphtheria is a local specific inflammation, and a constitutional disease. Its treatment must, therefore, be both local and general. Good results are obtained from astringents, the perchloride of iron being the most reliable. Solvents are also useful, as lactic acid, lime water, chlorate of potash, and steam. The best antiseptics are the permanganate of potash, carbolic acid combined with sulphate of iron, salicylic acid, boracic acid, quinine, sulphur, chromic acid, eucalyptus globulus, benzoate of sodium, chlorinated soda, and chloral hydrate. The diet should be concentrated and nourishing. Alcoholic stimulants must be employed boldly. I believe that alcohol is as antagonistic to diphtheria as belladonna to opium, or quinine to malaria. Patients with diphtheria will bear an amount of alcohol which, under any other circumstances, would not be tolerated.

DR. ASDALE spoke of the rapid necrosis and early detachment of diphtheritic membrane observable under the mercurial influence. The effects are recognizable usually before the end of the first twenty-four hours of treatment. Diphtheritic subjects tolerate and seem to require enormous doses of calomel, or of the corrosive sublimate; he preferred the bichloride, because of its prompt action, and because it can with great facility be administered in simple solution. To a child of five years he would give, unhesitatingly, one-eighth of a graln of the bichloride of mercury, or, ten grains of calomel, every two hours. These doses do not purge; do not pytalize; and do not interfere with alimentation. He desired especially to mention, that under no other medication in diphtheria had he found the appetite so well preserved. Occasionally, but infrequently, the gums are made slightly tender; hasty evacuation of the intestine may occur several times during the first day, but after this the bowels are moved but one or twice in the twenty-four hours; this is the rule. If the dose given of the bichloride proves excessive, vomiting will happen, and, perhaps, straining at stool; but no consequences more unpleasant; and only reduction of the dose is requisite.

Treatment must be energetic until no new exudate appears, and until the membrane already formed (if visible) is distinctly limited in its extent, and altered from its original, smooth, white, and shining appearance, to a dirty yellow, or brown color, with loosened edges, betokening a speedy separation—this will be manifest in twenty-four to forty-eight hours: the mercurial should then be withdrawn, or if continued, should be given in smaller doses for a little longer time; the corrosive chloride may now be advantageously combined with the chloride of iron, if there is severer constitutional depression, and alcoholic stimulants freely administered—this supplemental treatment will be found required *only* in the serious and protracted cases; generally, *a complete cure may be obtained in two or three days.* He urged the application of cold to the throat, if there is great swelling of the tonsils, œdema of the uvula, or tumefaction of the neighboring lymphatic glands; topical treatment he did not employ, other than cleanliness and comfort make necessary. Applications of any kind made

through the mouth or nose he regarded as generally worse than useless—to young children annoying and often a positive injury. Local medication alone can not be depended upon to do any good. If the obstruction be of the nose, or in the trachea, or larynx, we must be governed in the use of the mercury by the rational signs present, judging of each case and its needs by the mitigation or disappearance of the urgent symptoms. This assurance he could give that the remedial influence of the mercury may be confidently looked for, as a rule, within forty-eight hours from the institution of the treatment; provided, that it has been *timely* and *energetically* employed.

Dr. Asdale believed that early separation of diphtheritic membrane is accomplished by virtue of the antiphlogistic action of the agent employed; he thoroughly believed in the identity of membranous croup and diphtheria.

Experience had long since taught the medical practitioner that it is not only *not pernicious*, but beneficial and wise to employ antimony and turpeth mineral in the management of pseudo-membranous croup; the bulk of the profession has, however, yet to learn that the "alias" of the latter-named condition is diphtheria.

Medical authors and teachers of medicine, at the present time, do either ignore the subject of the mercurial treatment of diphtheria, or mention it but to slight it. Why is it so? Simply because of inexperience, because their minds are filled with the single idea of the dreadful asthenia (?) of this terrible disease, and they have not ventured to use that treatment which must, as they conjecture, but contribute to exhaustion, or, if attempted at all, it has been with a faltering, fearing hand, and hesitating thus, they have failed—and so failed to be convinced.

Dr. Asdale regarded diphtheria as a disease which (derived through contagion) must be met by early and energetic antiphlogistic measures; its course is swift; hence, if we are to be successful, it must be through the use of those agencies, which will most promptly and decidedly limit the extension of the inflammatory exudate, and which will accomplish this object with the least constitutional depression.

There is no specific cure for diphtheria; unfortunately, there are cases of the disease against which no treatment can prevail, but he believed that by the antiphlogistic (mercurial) treatment, more may be saved than by any other. He had employed this treatment, for over six years, in eighty cases; the deaths were eight. An analysis of the fatal cases would prove nothing against the treatment; they must have perished, taken as he had found them, no matter what had been tried. The deaths were all in cases of nasal and naso-pharyngeal diphtheria, except one, that a case of diphtheria of the fauces and trachea also in which death by suffocation occurred on the fifteenth day; a piece of membrane, in the act of coughing, lodged in the larynx.

The other seven deaths occurred, one on the eighth day, and one on the thirteenth; the remainder at dates varying between these: in all except two, the diphtheritic membrane had disappeared, and the fatal termination succeeded upon the development of uræmia—total suppression of urine being observed in several instances; continuing, in one case, for four days before death.

Dr. Lange, the reader of the paper, said: I am prepared, gentlemen, to hear those of you who have not employed this treatment, utterly condemn it; I did that before I employed it, and, unpleasant as it is, I can recall some cases ending fatally which, had they received it, would, it is now my belief, have terminated in recovery. I am constrained to come to this conclusion only by my employment of the treatment. I am much strengthened in my opinion of the benefits of the remedy, and of its tolerance in such doses, by the like opinion of every gentleman here who has employed it, but one, who has used it only in severe cases, and here he has "frequently used it with satisfactory results." To those of you, gentlemen, who object to the treatment, and, outside of this Club, you are of the large majority, I have to say that I cannot comply with your call for statistics—there are none. Neither can I explain the manner of the action of this remedy in diphtheria any more lucidly than you can that of the action of quinine in malaria or of mercury in syphilis.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, January 1, 1883.

First Vice-President, Dr. T. M. Drysdale, in the Chair.

DEATH FROM EMBOLISM.

Dr. Wm. Goodell reported the death of the patient, from whom he had removed an uterine myo-fibroma. (Case reported by Dr. Baer in the discussion on Dr. Drysdale's paper, at the meeting of December 7, 1882.) The patient had progressed favorably, but some weeks after the operation, while straining at stool, she had evidently loosened a portion of clot on the proximal side of one of the venous ligatures. It passed into the pulmonary circulation and quickly caused death.

WHAT IS THE PROPER MANAGEMENT OF THE BOWELS AFTER PERINEORRHAPHY?

Dr. Goodell had recently operated for the relief of lacerated perineum, upon an insane woman who had been sent to him for that purpose from an asylum. Her insanity commenced after labor, and was probably due to a complete laceration of the perineum extending two inches up the rectum. It had always been his habit to prevent any action of the bowels during the first week after the operation. This patient, soon after coming out from the influence of the anæsthetic, tore off the bandage from her knees, removed the catheter, and by severe straining efforts secured a movement from the bowels. As she could not be controlled, laxatives were given to secure liquid stools and avoid straining. The patient walked freely about the ward from the day of operation. The Doctor expected the operation to be a failure under such circumstances; but to his surprise, on removing the sutures, he found that in the rectal portion and the important part of the perineum union had taken place.

His attention has been called by this case to the question of the advisability of keeping the bowels constipated after this operation. He intends to try the effect of laxatives in future cases.

Dr. R. P. Harris reported the case of a woman who, after the operation of perineorrhaphy, would strain, and her efforts at defecation opened the wound to nearly its original extent. In a second operation on the same patient the bowels were kept free and union was perfect.

Dr. E. E. Montgomery, after operating for lacerated perineum, does not use a catheter, but allows the patient to pass her water, as he does not consider healthy urine disadvantageous for a wound. He has been in the habit of using compound liquorice powder to keep the stools liquid. He has had good success in both primary and secondary operations upon the perineum when the rectum was involved.

The following members were then elected

OFFICERS FOR 1883:

President.—Dr. Richard A. Cleemann.

Vice-Presidents.—Drs. B. F. Baer and W. T. Taylor.

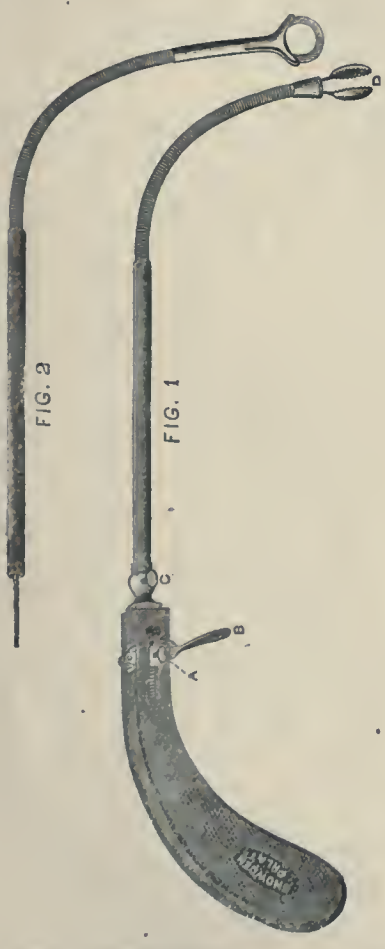
Secretary.—Dr. W. H. H. Githens.
Treasurer.—Dr. Alfred Whelen.
Librarian and Curator.—Dr. E. E. Montgomery.
Publication Committee.—Drs. John H. Packard, B. F. Baer, Elliott Richardson, James V. Ingham.
Councillors.—Drs. R. P. Harris, L. D. Harlow, Wm. Goodell, T. M. Drysdale.
Library Committee.—Drs. Horace Williams, D. M. Cheston.
Committee on Proceedings.—Drs. A. H. Smith, E. E. Montgomery.

NEW INVENTIONS.

FLEXIBLE TUBE FORCEPS AND GUILLOTINE.

BY CARL SEILER, M.D.,
OF PHILADELPHIA.

THE removal of foreign bodies and small neoplasms from the laryngeal cavity is often attended with considerable difficulty on account of the inability to reach and grasp the foreign body with the instruments at hand, even if it is plainly to be seen with the laryngeal mirror. The position of pins or fish-bones in the larynx is frequently such that a stiff forceps can not grasp them; either its blades open antero-posteriorly or laterally, and the bend or curve given to the instrument will often be found either too great or too small in a given case.



In order to obviate this difficulty, I had a Stœrk tube forceps altered by cutting off the curved portion of the tube and substituting for it a close spiral of steel wire ending in a bell-like tip. The steel wire to which the blades were attached I had replaced by a stout copper wire stiff enough to retain any course given to it, and at the same time flexible enough to allow of frequent changing of the course. The rings attached to the sides of the universal handle were replaced by a disk, so that no matter in which direction the course of the tube pointed the handle could always be held in the same position of the hand. The same change was made with the tube of the guillotine knife. This instrument I exhibited at the annual meeting of the American Laryngological Association in 1880.

The complicated nature of the Stœrk handle makes it, however, a very costly instrument and the position of the hand in holding it when the forceps or guillotine is used is rather awkward and it is difficult to hold the instrument steady. For these reasons I suggested a different handle, and Mr. W. Snowden made an instrument which answers the purpose admirably and of which the cut is an excellent representation.

The handle, made of ebony, is shaped like the butt of a pistol. The straight portion is hollow and contains a spiral spring, while it ends in a hollow central part into which the tube is fastened by a bayonet-joint and held fast by a set-screw (C. Fig. 1). The copper wire to which the forceps blades are attached, and which are seen projecting from the bell-tip at D, is fastened by the set-screw A, in a lever inserted into the handle the lower end of which, B, projects like the trigger of a pistol.

When the instrument is to be used, the handle is grasped like a pistol with the forefinger resting upon the trigger, by pulling which the blades of the forceps are drawn into the bell-tip of the spiral tube, and are thereby closed. The tendency of the spiral to elongate when pressed upon, causes a slight forward motion of the tip, this to a certain extent preventing the upward motion of the blades when they are closed, an accidental but admirable property of the instrument which facilitates the grasping of the foreign body or neoplasm in the laryngeal cavity. The flexible portion of the tube enables the operator to give it any desired curve, and simply turning the wire within the tube before its end is held in the trigger by the set-screw enables him to set the blades at any angle he may desire. It is necessary to have the straight portion of the tube stiff, as otherwise the instrument would bend close to the handle when a neoplasm or foreign body, which requires some force for its removal, is to be lifted out of the laryngeal cavity.

Fig. 2 represents the annular guillotine, which, like the forceps, can be bent to any desired curve and set at any angle, and which fits in the same handle.

CORRESPONDENCE.

THE LOCAL APPLICATION OF CARBON DISULPHIDE FOR THE RELIEF OF PAIN.

To the Editor of THE MEDICAL NEWS.

SIR: In the issue of THE MEDICAL NEWS for April 8, 1882, I brought to the notice of the profession the employment of the bisulphide of carbon for the relief of pain; the claim there advanced being that against pain neuralgic in character, the local application of this seldom used drug was almost certain relief, amelioration following in a vast majority of instances. That such a claim depends not alone on my own observations, but will stand the test of others, is shown by the following communications I have received from an independent and therefore unprejudiced observer, Dr. Alexander M. Stout, of Sussex, Waukesha Co., Wis.

Under date of January 10, 1883, he writes:

"In accordance with your request, I make the following report upon the use of carbon disulphide for the relief of neuralgic pains.

"An application of the drug was made, immediately after receiving it from New York, upon a middle-aged lady, who every week or two suffered from frightfully severe attacks of supraorbital neuralgia. I followed your directions minutely; several applications were made, but without any amelioration of the pain. The patient informed me that the medicine seemed to send darting pains all through her head, and refused to allow me to make another application. Next day she had an ugly brown patch at the seat of application, which remained a week or ten days. She is no longer one of my patients. I was somewhat disgusted.

"A short time after this, however, I applied the remedy for intercostal neuralgia upon a man, a fiddler by occupation, and who was unable to pursue his calling on account of what he termed 'neuralgia of the heart.' A physician near here had been treating him for some time for such a disease. As soon as the smarting which is produced by the carbon disulphide had subsided, he drew a long, deep sigh of relief, and with a broad smile said, 'Why, Doctor, you have cured me!' and went away protesting much gratitude. He has not since been troubled by any pain whatever.

"Since that application I have employed the drug daily, and with magical and most delightful success. I have no medicine which acts so quickly, easily, and promptly."

In a second letter he communicates the following interesting case, and brief remarks.

"Last Monday (Jan. 15, 1883) I was sent for to see one of my patients; a strong, robust man, who I have had under treatment for several days for a light attack of pneumonia. Upon reaching his bedside, he informed me that he should go crazy, wild, if he had to suffer any longer from the pain in his head, an occipital and frontal neuralgia. In three minutes he was resting quietly, entirely relieved by our remedy. I sincerely feel under obligations to you in this matter, as the drug has been so great a help to me in so many intractable cases of neuralgia, whereas, before I had the bisulphide, many patients went unrelieved and dissatisfied away from me."

After such earnest testimony as to efficiency of the drug, by Dr. Stout, comment on my part is rendered unnecessary.

Very respectfully yours,

E. SANDERS, M.D.,

Attending Physician to the Dispensary Department of Mt. Sinai Hospital.

NEW YORK, January 24, 1883.

CONFIDENTIAL COMMUNICATIONS.

To the Editor of THE MEDICAL NEWS.

SIR: A writer in THE MEDICAL NEWS of January 20th urges the adoption by the legislature of Pennsylvania of a statute of the State of New York, which prohibits a practising physician from disclosing, under any circumstances, any information which he may have acquired in a professional character, which information was necessary, on his part, for a thorough understanding of his patient's case. If I remember rightly, the legislature of Pennsylvania at its last session was asked to pass a similar law; and it would seem probable that our present legislature will be urged to enact a measure similar or identical in character with that of our northern neighbor. It would seem that, in accordance with traditional policy, New York having taken physic, Pennsylvania must be purged.

Strangely enough, the expressed desire for such a statute seems to come from members of the medical profession. I have no doubt that this feeling has its origin in an honorable and chivalrous desire to be faithful to those personal trusts that are confided to the physician by those who are the objects of his professional care; and within certain limits the sentiment is a just and proper one. But it should not be carried to the extent of depriving us of just means for our own protection, nor of making us the virtual abettors and accomplices of vice and crime. "An accessory after the fact," says Wharton, "is one who knowing a felony to have been committed by another, receives, relieves, comforts, or assists the felon," and although the enactment of such a statute might change the legal consequences of such an action, its moral effect when done for the purpose of shielding the felon from just punishment, must remain just what it has ever been deemed in the past, as detrimental to the general welfare.

The reasons assigned by the writer of the article alluded to in support of this measure are these: 1st. Where a husband has acquired syphilis by illicit sexual intercourse, he will feel greater freedom in stating all the facts of his case to his attending physician if he is aware that his medical attendant is restrained by law from testifying in court to any knowledge thus gained, thereby enabling him to escape a conviction for adultery or for any other crime committed by him as an incident of his illicit intercourse. It is claimed that the more thorough knowledge thus gained will enable the physician to treat his patient more efficiently than he could otherwise do.

It is difficult to understand how the details as to the precise time, place, and manner in which the disease was acquired, or a knowledge as to the particular person from whom it was derived, can promote the efficiency of its treatment; for this disease, in its primary character, is readily and certainly recognized by any one who is competent to treat it. On the other hand, it may well be claimed that the proposed measure would remove one of the strongest barriers which now exist against indulgence in sexual vice, and it would certainly give to it an additional protection.

The second reason assigned in favor of this measure seems entitled to still less favorable consideration than the former one. It is this: "A man in attempting a burglary is met by an excited and outraged opponent, who strikes to kill, and" (the burglar, we suppose) "receives a blow in the temporal region. There exist really a fracture of the bone and laceration of the middle meningeal artery." The criminal eluding arrest, and not understanding the gravity of his case, applies to a surgeon for treatment, and deceives him as to the nature of his injury, by a false statement as to the manner of its reception; and the loss of his valuable life is the dire consequence. "Other cases," says this writer, "suggest themselves" (similar accidents, occurring in the perpetration of rape, highway robbery, and murder would be likely to suggest themselves in this connection); but he seems to think that these are sufficient to induce the legislature of Pennsylvania, and of every State in the Union, to enact a statute similar in effect to that which now exists in New York.

If all that can be said in favor of such a measure amounts to this, that it will more effectually shield vice, and that it will more efficiently protect crime, by bestowing additional secrecy to the one, and enhanced safety to the other; that it will serve to lighten or to obviate the penalties that may be incurred by the commission of such crimes as adultery, rape, burglary, and murder, it would scarcely seem wise in our present lawgivers to hastily overturn the common law, which has hitherto so justly defined and regulated our duties in this regard, and to substitute in its place a statute

from which neither our profession nor the honest and virtuous portion of society can derive any advantage, but one whose benefits, if any, could only accrue to the vicious and the criminal classes.

Before the members of the medical profession "put their foot into it," by securing the enactment of such a statute as that of New York, it would be well for them to consider carefully the consequences which must necessarily result to themselves from its adoption. The New York statute, which it is proposed to adopt, is in the following words:

"No person duly authorized to practise physic or surgery *shall be allowed* to disclose any information which he may have acquired in attending any patient in a professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon."

It will be readily seen that this law effectually prevents a physician from giving testimony in his own behalf in suits that may be instituted against himself for malpractice, as well as in suits which he may bring against delinquent patients to recover just payment for his services: and he frequently can have no other evidence by which he can establish the justice of his cause. In illustration of this point, I will briefly relate a case which recently occurred in my own practice. A resident of New York, temporarily in this city, fell or was thrown from a wagon, causing a fracture of both tibia and fibula of right leg at upper portion of lower third. On being called to attend him I made particular inquiry as to his occupation, his habits, and his previous health. I was told by him that he was an agent, that he was temperate, and that he had always been healthy. He especially disclaimed having ever had any specific disease. I adjusted his limb, secured its position by the necessary appliances, and bestowed upon him all requisite attention and care during the next forty days. At the end of that time, on removing the dressing from his limb, I was surprised and disappointed at finding that while the length and shape of the injured limb were all that could be desired, no bony union had taken place. Feeling confident as to the cause of this condition of his limb, I at once charged him with having deceived and misled me in regard to his previous health, and he promptly admitted having had syphilis a year or two previously. Upon further investigation I found conclusive evidence of the correctness of his confession. The reason which he assigned for concealing the truth, was that he supposed himself cured, and did not think it necessary to disclose to me at the time of the accident any knowledge concerning it. This was confided to me as a professional secret, and I could not prove by any testimony, save my own, that such an admission had been made by him, and I suppose that it would be utterly impossible for me to establish by any other evidence the fact which he privately admitted to me, and "*which information was necessary to enable him* [me] *to prescribe for such patient*" at that juncture of his case. As he was anxious to return to his home, I prescribed the standard anti-syphilitic remedies, encased his leg in plaster of Paris, and left him to go on his way, since which time I have heard nothing from him.

Now, supposing—just what has many times occurred to others—that I should be required to respond to a suit for damages for failing to procure the usual bony union in this man's broken leg (and as the fellow left without paying me a dime for my services, he may yet, in accordance with established precedent, attempt to compensate me by such a procedure), then this much lauded New York statute, if operative in Pennsylvania, would effectually debar me from making a successful defence or of establishing before a court the facts that would be necessary to a proper understanding of the case. One of those conscienceless shysters who especially exult in the winning of an unjust cause, with this New York statute before him and in force, would find in the facts which I have stated, all the necessary materials for a promising suit for malpractice. A professional friend and fellow-townsman, and one of the most worthy and competent surgeons of our State, is now a defendant in a suit for civil malpractice. The situation is such that he will be compelled to depend largely on his own testimony for his defence. This New York statute would effectually close his mouth, and leave him an easy victim to his prosecutors.

As to the ethical obligations of physicians to their patients, I believe that this has generally been observed to as great a degree as either good morals or sound policy would dictate, and that these had better be left, as in the past, to the moral sense and honorable instincts of the members of the healing art—leaving each one to judge for himself in every case just what are his duties to his patient, and what are his obligations to the State.

The better elements of society would in no wise be benefited by the enactment of the proposed measure; our profession would gain nothing in dignity, character, nor honor, and might lose much in reputation and purse; and the only advantages resulting from it will accrue to the devotees of vice, the perpetrators of crime, and the promoters of suits against medical men for civil malpractice. These interests deserve no additional protection, and society can illy afford to invest them with any additional safety and strength.

Against the adoption of a measure so detrimental to the better interests of society, and so fraught with injury to the medical profession, I desire to enter my sincere and earnest protest.

Very truly yours,

JOHN B. CRAWFORD, M.D.

WILKES BARRE, January 22, 1883.

BOSTON.

(*From our Special Correspondent.*)

THE CHILDREN'S HOSPITAL.—The Children's Hospital, now in its fourteenth year, has just moved into a new and handsome building, erected for the purpose at a cost of about $40,000. Heretofore the hospital has occupied a large dwelling-house, which latterly became too contracted for the needs of the institution.

To Dr. Francis H. Brown, of Boston, is due the foundation and organization of this charity. He was greatly assisted by the influential aid of the late Dr. Chandler Robbins, whose eloquence opened the purses of the wealthy men of Boston, and to this fact is due the large meed of praise given to Dr. Robbins. But it is undoubtedly true that the plans and ideas gathered by Dr. Brown while in Europe were the seed-germs of this hospital. And he is still not only actively engaged in its development, but, as Secretary of the Board of Management, he has been untiring in perfecting the arrangements and suggesting many of the conveniences of the new building. It stands on the new land (Back Bay) at the corner of Huntington Avenue and Camden Street. It is a sightly structure of brick, composed of centre building with wings, only one of which is as yet completed. Out of the large entrance hall intersecting passages lead right and left to the wings, which are two-story pavilion wards; the lower story in the completed wing is occupied by the boys. Walls are tinted, hung with pictures. Tables in the centre are used for the children's books and toys. The little fellows have an adjoining dining-room supplied with

low tables and chairs. Beds are of iron, of convenient pattern. Floor of hard wood. Abundance of sun and light make the ward as cheery as out-of-doors. At one end is a section called the "sun-room," into which sunlight pours all days. The floor is underlaid with steam-pipe. Heat and ventilation are admirably managed, and so arranged that fresh air will enter from either side, according to the direction from which the wind is blowing. This is controlled by means of valves.

Bath-rooms have marble floors. All plumbing and piping are open throughout the house. An excellent idea. The building is finished interiorly in ash. The girls' ward is directly over the boys' room, and corresponds in all ways. On the lower floor and in basement of the central building is a fine operating-room; roomy dispensary; an ether-room, where patients are prepared for operations; an accident-room; a plaster-room, where casts are made and plaster jackets applied; a splint-room, in which the surgeons may modify and invent apparatus, a smith being employed and all tools at hand; also laundry, kitchen, and sitting-room for the sisters who act as nurses. In each ward dining-room is a medical closet for the ward. There are also diet and ward kitchens. Nothing in the way of convenience has been forgotten.

On the second and third stories of the central building are handsomely furnished rooms, to be used privately for mothers who may wish to come with sick children and pay board. One floor is devoted to contagious diseases. It is completely shut off from the rest of the house, and can be reached from without the house by a passage which protects the hospital from all possible exposure. The walls of the whole house have four coats of hard paint and one of varnish. The whole is as perfect as modern science can make it, and may justly be regarded with pride.

HOSPITAL FOR INCURABLES.—A new institution has recently been inaugurated—a hospital for incurables, under the charge of Dr. Hamilton Osgood. This supplies a want which has been bitterly felt. In Boston incurables are not admitted to the large hospitals. Until now there has been almost no refuge for the incurable among the poor, and what to do with them has been a painful difficulty. The response to an appeal for funds towards this object has been quick and generous. The hospital is located in one of the suburbs, a few minutes' drive from the city, in a sunny and healthful spot, and at present occupies a large and handsome cottage, capable of accommodating twenty-five patients. This is a nucleus of what undoubtedly will become a large institution, for incurables are many. Every city requires a similar home for such of its poor incurables as could not, with propriety, be sent to an almshouse.

CHAIR OF ANATOMY AT HARVARD.—Dr. Thomas Dwight is giving satisfaction as a substitute for Dr. Holmes, during the remainder of the current year, at Harvard Medical School. One can easily imagine the difficulty of sustaining this position when suddenly called to it without sufficient preparation in the way of models, plates, etc., especially in the middle of a term.

CHICAGO.

(*From our Special Correspondent.*)

THE NEW COLLEGE OF PHYSICIANS AND SURGEONS has become involved in a singular, probably unparalleled lawsuit. Three students who had attended the last spring course at the Rush Medical College, entered this winter at the new College with the hope of graduating at the end of the term. This hope was based, as they allege, upon a definite promise on the part of Prof. A. Reeves Jackson, with the approval of Drs. Rea and Carpenter, that they should be admitted as senior students, and entitled to the final examinations at the end of the term, although they had only studied one spring term at another institution. At any rate the students are in possession of matriculation tickets admitting them to the senior class. Prof. Jackson admitted that he had given the promise to let them apply for graduation at the end of the term, but had done so without full knowledge of all the facts. The Faculty, however, concluded to abide by the rules of the State Board of Health, and refused to admit to the final examination any student who had not taken two full courses of lectures in some medical college. They hence offered these students to refund their fees. The latter, however, refused to accept them and have sought redress in the courts. One of them, M. I. Hendrix, has begun a test-case, in which he sues the Faculty for $5,000 damages for violation of contract.

CANADA.

(*From our Special Correspondent.*)

PUBLIC HEALTH.—The Dominion Government has acted upon the resolutions presented by the Convention, held a few months ago in Ottawa, and organized a system for the collection of vital statistics in the principal cities.

BODY-SNATCHING IN MONTREAL.—As previously mentioned in THE NEWS, a considerable proportion of the subjects supplied to the medical schools here are "raised." The practice has prevailed this winter to a greater extent than usual, owing to the larger number of medical students in the city and the high price paid for subjects by the demonstrators, in some cases as much as $30 apiece. Not a week passes without reports from the small towns and villages that the vaults have been broken and the bodies stolen. In some instances the relatives, with the aid of a detective, are able to recover the corpses, but in the majority of the cases they are hidden away and not put on the tables until the search is over. Public opinion is aroused and the matter is again before the legislature, but nothing will be done to remedy matters until the various asylums and poor-houses receiving government aid are compelled to send the unclaimed dead to the colleges.

LONDON.

(*From our Special Correspondent.*)

THE LONDON MEDICAL SOCIETIES.—The Christmas vacation is over, the medical schools have reassembled, and the various medical societies are hard at work again. The Pathological and Clinical Societies have recently held their annual meetings for the election of officers and other formal business. In these societies, as in the older Medical and Chirurgical Society, the chairman holds office for two years, and a physician and surgeon are elected alternately. The late President of the Pathological Society—the most largely attended of all—was Dr. S. Wilks, Senior Physician to Guy's Hospital. He is, of course, well known in America as the author of a *Handbook on Pathology*. He has long been a most arduous worker in this field of inquiry, and was one of those to establish beyond question the existence of visceral syphilis. The new President is Mr. J. W. Hulke, Senior Surgeon of the Middlesex Hospital, and Surgeon to the Moorfield's Ophthalmic Hospital. He is a very worthy successor to Dr. Wilks, for although not so widely known as many others, there is no man more thoroughly well informed on all the scientific branches of the profession than he. The Clinical Society has been presided over for the last two years by Prof. Lister. When he was elected he was a comparatively new member of

the Society, and had not attended its meetings, and some disappointment was felt and expressed by some who had served the Society from its foundation at having been passed over. Indeed, Mr. Lister's election has caused some two or three old members to absent themselves from the meetings for the past two years. But in spite of that, Mr. Lister's presidency has been a very successful one, and there can be no doubt that it has reflected far more honor upon the Society than upon himself. The Clinical Society is the youngest of our London societies, and its action in thus seeking out its most distinguished member to be its President, irrespective of the date of his membership, is a sign of its healthy life. The fact, moreover, is an indication of the honor in which Mr. Lister is held by the younger members of the profession, while among his seniors there is a tardiness in accepting his antiseptic treatment of wounds. Dr. Andrew Clark, of the London Hospital, a physician in large practice, who attends Mr. Gladstone, and is one of our medical orators, is the newly elected President of this Society.

At the Meeting of the Clinical Society on January 12th, Dr. Coxwell exhibited a child, aged thirteen, with symptoms resembling those of *Myxœdema*. Until eight years of age she differed in no way from other children, and could read a chapter out of the Bible or a story as well as her mother; could write, and learnt arithmetic. A great change then came over her. She would often fall asleep, even when eating her meals, her memory became defective, and if sent to do anything she would wander about in an aimless fashion. Later her speech became thick and indistinct; she suffered from headache, her head drooped forward on her chest; her hands and feet became very cold; her legs became weak and her gait unsteady. She was lately a patient in the National Hospital for the Paralyzed and Epileptic, under the care of Dr. Hughlings Jackson. The appearance of her face is very suggestive of myxœdema, her skin being translucent, with a circumscribed patch of redness in the centre of the cheeks, the lower eyelids swollen, the nose broad, the eyes prominent and heavy looking, The limbs are slender and well formed. The thyroid gland seems diminished, and there are no abnormal fatty tumors in the region of the neck or elsewhere. While under observation her temperature was frequently as low as 95.6°. She was often extremely restless at night, and had frequent attacks of screaming. Her power of speech became worse, till at last she could hardly utter a single sound, the lips being seen to move ineffectually when she attempted to do so. She could not kiss her mother nor puff out her cheeks, and her food would often remain seven or eight minutes between her teeth and lips. There was a general overclouding of the intellect. Dr. Coxwell drew attention to the fact that very pronounced mental disease has been reported in myxœdema, and that Dr. Ord has had a patient suffering from that disease with marked affection of the bulb, a point of similarity with the present case of some importance. If the case was one of myxœdema, it was of interest as being the first recorded in a child. If it was one of simple imbecility, it was remarkable on account of the bulbous symptoms and the likeness it bore to myxœdema. The arguments in favor of sporadic cretinism were few, and outbalanced by the absence of most of the characteristics of that disease.

Mr. J. N. C. Davies-Colley read notes of a case of *Enormous Enlargement of the Lower Lip Cured by Operation*. Richard B. D., a clerk, aged 36, was admitted into Guy's Hospital in August, 1881, with a remarkable swelling of the lower lip. Fourteen years before he had a chancre on the penis, followed by soreness of the tongue and swelling of both lips, especially the lower. There was never any rash on the skin. He was a very great drinker. The lower lip was of enormous size, everted, and pendent, so that its border was on a level with the tip of the chin, while the lower teeth were in front completely exposed to view. The mucous membrane was fissured in parts, but otherwise natural. The tissues were a little firmer than usual, but not at all indurated. There was a little tenderness on pressure. From side to side it measured 3 inches, from above downwards 1¼, and in thickness ⅞ of an inch. The upper lip and tongue showed signs of chronic inflammation. There was no enlargement of the adjacent glands. He left off smoking, and was at first treated with antisyphilitic remedies. The mucous membrane became more healthy, but the lip remained the same size. Some reduction was then effected by pressure between thin strips of wood. The lip became smaller and flaccid, but was still morbid and pendent. On November 8th a V-shaped piece was removed from the centre of the swollen lip, and a rapid recovery ensued. When last seen he had no longer any eversion of the lip, which had assumed a perfectly healthy and normal aspect. Mr. Davies-Colley brought the case forward as a striking example of the enlargement of the lip which occasionally results from chronic inflammation. There was nothing in the patient's family history to indicate a scrofulous tendency. The evidence of secondary syphilis was doubtful, and there was no record of mercurial salivation. On the whole, Mr. Davies-Colley was disposed to attribute the disease primarily to syphilis, and secondarily to the constant irritation of the inflamed surface by excessive smoking. The case was also interesting on account of the success which followed excision of part of the lip, after the more or less complete failure of other remedial measures.

Mr. Clement Lucas had seen this case, and bore testimony to the excellent result obtained. He thought that any chronic ulceration might produce such hypertrophy, as was seen in struma. But he suggested that the internal use of mercury might have had some effect in its causation.

Dr. Hadden said the case appeared to resemble cases of lymphatic obstruction of the tongue described by German authors—the microscopical characters bore out that view.

Mr. Lister remarked on the fact that removal of a portion of such chronically indurated tissue is often followed by recovery of what is left behind, and instanced what is seen in operating on lipoma nasi, and hypertrophied tonsils.

Mr. Davies-Colley thought that the tension of the parts and the correction of their pendulent position explained the recovery of the unexcised portions of the lip. There were no enlarged glands, or any other direct evidence of lymphatic obstruction.

Mr. H. Golding-Bird then read a paper on a *Successful Case of Transpatellar Excision of the Knee*, which he had previously shown to the Society.

The operation was on the person of a lad, æt. 13, fairly healthy himself, but with a family history of phthisis. There was a year's history of articular ostitis of the right knee, with pulpy disease. Excision was eventually performed on May 9, 1882. It differed from an ordinary excision in that the transverse incision was made across the middle of the patella, which was then sawn in two; the two fragments, with the soft parts, being bound up and down. The excision was then completed as usual, the articular surfaces of the tibia and femur being removed. Some pulpy thickening was removed from the under side of the patella, and when the limb had been straightened two car-

bolized silk sutures were passed through its substance, and so its two fragments were united.

Primary union was obtained, and nothing more was seen of the patellar sutures. Until September 12th, he walked about with a stiff bandage at the knee, and with crutches; after that date he was ordered to discard all support. He has a movable patella and half an inch shortening. He has all the advantages of retaining the patella; but besides that, there is a gain by this method of operating, since the surgeon can freely examine and manipulate the joint—more freely, indeed, than where, with the idea of retaining the knee-cap, the lateral incisions are employed. Two great advantages remain to the patient by keeping the normal attachments of the patella. The quadriceps opposes the hamstrings, and so does away with the necessity of employing a stiff bandage for years to prevent posterior displacement of the leg; the rectus femoris, considered as arising below, has its full play upon the trunk in preserving equilibrium, whilst it also allows of the perfectly natural forward motion of the limbs in walking, and this last is not the case where the ligamentum patellæ has been solidified.

MR. GANT thought that when excision of the knee was required, it was rare to find the patella free from disease; his results after removal of the patella had been very good.

MR. CHRISTOPHER HEATH agreed with Mr. Gant, and thought that when the patella remained free from disease it afforded an argument against excision. Mr. Golding-Bird's case was undoubtedly very successful, but it was probably capable of other treatment, and excision at such an age usually interfered seriously with the growth and utility of the limb.

PROF. LISTER said that Volkmann had advocated this operation many years before. In cases without sinuses he should think it good, if the operations were conducted aseptically; but if he thought only of the old method of conducting the operation, he should agree with Mr. Gant and Mr. Heath. He had had many successful results in cases like Mr. Golding-Bird's from free antiseptic incision into the joint, with gouging out of carious bone, and scraping away of diseased synovial membrane; getting even movable joints.

THE COLLECTIVE INVESTIGATION COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.—An attempt is being made in this country by the British Medical Association to obtain information on the etiology, natural history, and treatment of disease, from the large body of practitioners scattered over the country. With this object, a committee for the collective investigation of disease has been formed, and Dr. Mahomed has been appointed secretary. The committee has just issued a letter asking for reliable information bearing on the contagious nature of phthisis. A meeting is to be held in London this week, at which Sir James Paget and Sir William Gull are announced to speak on this subject. Those who have been engaged in general family practice will appreciate the extreme difficulty there is in obtaining from it reliable scientific data. It is also well known that while in "union is strength," in "numbers is weakness." Each fresh observer introduces new possible sources of error in observation; and in an investigation undertaken by hundreds, it is impossible that the sense of individual responsibility should not be seriously diminished. The greatest possible care will be necessary on the part of the committee in analyzing the reports they receive, and in estimating their value.

THE NEW SURGEON-GENERAL OF MAINE.—DR. AUGUSTUS C. HAMLIN, of Bangor, Me., who has lately been appointed surgeon-general of Maine, on the staff of Governor Robie, is one of the prominent physicians of New England. He served in the army during the entire war, being intrusted with many important commands. He was afterwards promoted to be medical director in the regular army and in the army of West Virginia.

THE HAMMOND PRIZE.—The American Neurological Association offers a prize of $500, to be known as the "Wm. A. Hammond Prize," and to be awarded at the meeting in June, 1884, to the author of the best essay on the *Functions of the Thalamus in Man.*

The prize is open to competitors of all nationalities. Essays are to be sent to Dr. E. C. Seguin, 41 W. 20th Street, New York, on or before February 1, 1884.

DR. BILLINGS will deliver a lecture this evening on "Germs and Epidemics," in the Free Saturday Lecture Course, under the auspices of the Biological and Anthropological Society of Washington, D. C.

THE second session of the German "*Kongress für innere Medicin*" will be held in Wiesbaden, from April 17 to 20, under the presidency of Prof. Frerichs.

ABSENCE OF SPLEEN.—PROF. SCHENTHAUER, according to the *Medical Times and Gazette*, recently found at an autopsy of a woman aged seventy that no spleen existed. The organ had not been destroyed by disease, but was congenitally absent.

SMALLPOX STATISTICS FROM PITTSBURG, PA.—From the annual report of the Registrar of Pittsburg, Pa., for 1882, we extract the following figures concerning smallpox. During the year there were 1136 cases, 300 of which proved fatal. Of the 300 deaths, 235 occurred during the first or winter quarter, 46 during the second quarter, 3 during the third, and 16 during the fourth quarter.

In the municipal hospital, 313 cases were treated. Of these 124 were of unvaccinated persons, and 189 of those who had been previously vaccinated; of the latter 26 died, equal to 13.76 per cent.; of the former 61 died, equal to 49.19 per cent.; of the 26 post-vaccinal deaths 17 or 65.4 per cent. exhibited one vaccine scar, 6 or 23.1 per cent. exhibited two scars, and 3 or 11.5 per cent. showed three scars. The ages of those who died from smallpox after vaccination were: from 15 to 20 years, 2 persons; from 20 to 30 years, 10; from 30 to 40, 8; and from 40 to 50, 6 persons,

WINTER CHOLERA.—The disease to which this significant name has been applied appears to be coming into notice at the present time. In the health bulletins for the week ending January 27, we meet with it in two large sections of the country. The Michigan report states that one of the health officers reports "many cases of winter cholera, which comes on very suddenly and is severe;" and Dr. Bryce, Secretary of the Ontario Board of Health, speaks of it as follows: "Among the peculiar features of this extremely cold week, is the fact that in District IV., whence are reported over seven hundred cases of disease, diarrhœa not only becomes one of the six most prevalent diseases, but it amounts to five per cent. of all the diseases reported. Extreme cold as well as extreme heat would seem to have the same tendency; but while we must suppose that the former acts by producing internal congestions, the latter induces the disorder by the irritative effects of fermentative changes."

250 cases are reported at Waterbury, Conn., and the disease is thought to be due to the snow-water in the city reservoirs.

THE HOMŒOPATHS AND THE NEW YORK CODE.—At the annual meeting of the Homœopathic Medical Society of the State of New York, held at Albany last Tuesday, the President, Dr. John J. Mitchell, delivered an address which is interesting reading just now, and from it we make the following extracts:

"We had thought the battle for Homœopathy won. We were content, perfectly. Our schools were increasing, and our numbers never so large. Hospitals, dispensaries, and insane asylums were coming under our control in numbers rather greater than our professional corps could thoroughly man. As to success in our practice, we had presented statistics until we are tired, all demonstrating to the unprejudiced student that in the great mass of curable diseases our mortality was scarcely one-half that of our professional brethren of the 'Regular' school. The wealth and intelligence of the land saw our success, and to a wonderful extent had become our patrons. Necessity had produced us specialists in almost every department of medical science; and as to consultations, we were in the state of the milkmaid in the nursery rhyme, who replied:

"'Nobody asked you, sir!' she said."

. . . . . .

"But amid all this prosperity and peace, without our knowledge, and certainly not in obedience to any request of ours, a clause was incorporated in the Code of Ethics of the Medical Society of the State of New York to the effect that 'Members of the Medical Society of the State of New York, and of the medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine.' . . . .

"This change of position met the hearty approval of the public, and the members of the Society were applauded for the noble, consistent position they had assumed.

"We, as homœopathists, were of course pleased that our 'regular' brethren had finally taken their stand upon the platform of freedom of medical action, upon which we had been for nearly a score of years. . . . .

"In regard to the resolution offered by the 'regulars' last year, we would state we did not directly or indirectly ask any such action. The resolution having been adopted, we hailed it as a good omen. Not that we thought the 'regulars' were becoming homœopaths, but that war might cease. We knew that we could do them good in the department of the practice of medicine to which for half a century we had specially devoted ourselves. And then they could be of service to us in the various departments of surgery, pathology, hygiene, and climatology, which we had more or less delegated to them. Any response on our part was not necessary, for they were merely coming to the position that we had occupied for a score of years. . . . .

"We are then to continue as a school of medicine, distinctively liberal in its character, ever holding out hands of welcome to any one educated to the level we have fixed; yes, refusing no one, provided he be lawfully educated as a physician, and honorable and true. . . . .

"In the triumph of the cause I advocate to-night all party lines shall be broken. Then the banners of the 'Eclectics,' of the 'Regulars,' and of the 'Homœopathists,' shall be lowered, in order that—the party watchwords having been erased—the noble legend of 'Scientific Medicine' may be emblazoned thereupon."

ADDITIONAL FRUITS OF THE NEW CODE.—A bill was introduced in the New York Assembly, last week, by Mr. Quinn, which provides that the right of every citizen and of the people to employ for medical purposes the services of any individual in whom he or she may have confidence, whether such employé has or has not a medical diploma, or has or has not registered as a physician, shall not be questioned in the State of New York. No such employé shall be liable to fine or imprisonment for rendering such service, where guiltless of any false representation in connection therewith, provided that nothing in this Act shall be so construed at to exempt from liability any such employé on account of damage resulting from malpractice, misconduct, or intoxication, either at common law or in pursuance of any statutory provision of this State.

PORRO'S OPERATION.—PROF. CARL BRAUN has performed Porro's operation in Vienna nine times. In eight cases the pedicles were treated by the extra-peritoneal method, and five recoveries were recorded. These five women are living now in Vienna, and are exhibited annually at the clinic. The ligatures in Prof. Braun's last case were of strong silk, prepared antiseptically, and were most carefully applied.—*Brit. Med. Journal*, January 6, 1883.

At a late meeting of the Obstetrical Society of London, DR. HEYWOOD SMITH exhibited a uterus removed by Porro's operation. The patient was aged twenty, the conjugate diameter of whose pelvis was an inch and three-quarters or less. She had been in labor two days, and attempts at delivery by craniotomy and cephalotripsy had been made without success. The performance of Porro's operation occupied nearly an hour. The specimen showed clearly the rugæ on its peritoneal surface.

The case died on the fourth day. The wound had perfectly healed, there was scarcely any trace of peritonitis, there was no fluid in the peritoneal cavity, and the tongue remained clean and moist to the last. There was, however, some incipient sloughing of the vagina, which he considered due partly to the length of time the patient was allowed to be in labor, and partly to the attempt, though it was not prolonged, at extraction with instruments in a case that was enfeebled by struma.

REVERSED HEREDITY.—Mlle. Bernard, the daughter of Claude Bernard, has just been fined one franc by the police tribunal of Boulogne-sur-Seine, on complaint of her neighbors, for converting her entire courtyard, garden, parlor, and even her bed-room, into an immense kennel for the care of destitute dogs. She felt that some reparation was due the canine race for the miseries inflicted on it by her father's vivisections.—*Revue de Thérap.*, November 1, 1882.

HEALTH OF PROF. OWEN.—*The Lancet* states that the health of PROF. OWEN is such as to cause great anxiety to his many friends.

GERMAN MALEVOLENCE.—The feeling in France towards Germany is well expressed by the following note published under the above caption in the *Journal Médicale de Paris* for November 4, 1882: "The celebrated German surgeon, Esmarch, the same who, by marrying a Princess of Schleswig-Holstein, became the uncle by marriage of the grandson of the Emperor William, has just published a brochure in which he attributes the death of the late President Garfield solely to the irrational treatment to which he was subjected by his physicians. The ball fired by Guiteau struck no essentially mortal organ, and the unjustifiable attempts to extract the ball, the employment of insufficiently and obsolete antiseptic dressings caused such a degree of prostration that a slight hemorrhage was sufficient to cause death.

"The account which we published of the autopsy of the unfortunate President shows that the views of Esmarch are as malevolent as erroneous. It seems useless to us to defend our American *confrères* who

showed under such circumstances as much practical science as professional devotion."

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending February 3, 1883, indicate that intermittent fever, measles, and rheumatism have increased, and that diphtheria, tonsillitis, and diarrhœa have decreased in area of prevalence.

Compared with the average for the month of January in the preceding six years, neuralgia, tonsillitis, and measles were more prevalent, and remittent fever, whooping-cough, and diphtheria, less prevalent during the month of January, 1883.

Including reports by regular observers and by others, diphtheria was reported present during the week ending February 3, and since, at 19 places, scarlet fever at 18 places, and measles at 17 places. Smallpox was reported at St. Joseph, Berrien County, February 3.

NOTES AND QUERIES.

PAY THE DOCTOR'S BILLS.

ON a blank account for professional services rendered, we find the following printed on the margin:

"Tres medicas facies habet; unam quando ragatur,
Angelicam; mox est, cum juvat, ipse Deus.
Post ubi curato, poscit sua præmia, morbo,
Horridus apparet, terribilisque Sathan."

Enricus Cordus.

"Three faces wears the doctor; when first sought,
An angel's—and a God's, the cure half wrought;
But, when that cure complete he seeks his fee,
Satan vile looks then less terrible than he."

THE DOCTOR'S DREAM.

I AM sitting alone, by the surgery fire, with my pipe alight, now the day is done:
The village is quiet, the wife's asleep, the child is hush'd, and the clock strikes One!
And I think to myself, as I read THE NEWS, and bless my life for the peace upstairs,
That the burden's sore for the best of men, but few can dream what a Doctor bears;
For here I sit at the close of a day, whilst others have counted their profit and gain,
And I've tried as much as a man can do, in my humble manner, to soften pain:
I've warned them all, in a learned way, of careful diet, and talked of tone.
And when I have preached of regular meals, I've scarcely had time to swallow my own.
I was waked last night in my first long sleep, when I crawled to bed from my rounds dead beat.
"Ah, the Doctor's called!" and they turned and snored, as my trap went rattling down the street!

I sowed my oats, pretty wild they were, in the regular manner when life was free,
For a Medical Student isn't a Saint, any more than your orthodox Pharisee!
I suppose I did what others have done, since the whirligig round of folly began,
And the ignorant pleasures I loved as a boy—I have pretty well cursed since I came to be man.
But still I recall through the mist of years and through the portals of memory steal
The kindly voice of a dear old man who talked to us lads of the men who heal,
Of the splendid mission in life for those who study the science that comes from God,
Who buckle the armor of Nature on, who bare their breast and who kiss the rod.
So the boy disappeared in the faith of the man, and the oats were sowed, but I never forgot
There were few better things in the world to do than to lose all self in the Doctor's lot.
So I left the life that had seemed so dear, to earn a crust that isn't so cheap,
And I bought a share of a practice here, to win my way, and to lose my sleep;
To be day and night at the beck and call of men who ail, and women who lie;
To know how often the rascals live, and see with sorrow the dear ones die;
To be laughed to scorn as a man who fails, when Nature pays her terrible debt;
To give a mother her first-born's smile, and leave the eyes of the husband wet;
To face and brave the gossip and stuff that travels about through a country town;
To be thrown in the way of hysterical girls, and live all terrible scandals down;
To study at night in the papers here of new disease and of human ills;
To work like a slave for a weary year, and then to be cursed when I sent my bills!

Upon my honor, we're not too hard on those who cannot afford to pay,
For nothing I've cured the widow and child: for nothing I've watched till the night turned day;
I've earned the prayers of the poor, thank God, and I've borne the sneers of the pampered beast,
I've heard confessions and kept them safe as a sacred trust like a righteous priest.
To do my duty I never have sworn, as others must do in this world of woe,
But I've driven away to the bed of pain, through days of rain and through nights of snow.

. . . . . .

As here I sit and I smoke my pipe, when the day is done and the wife's asleep,
I think of that brother-in-arms who's gone, and utter—well, something loud and deep!
And I read THE NEWS and I fling it down, and I fancy I hear in the night that scream
Of a woman who's crying for vengeance! Hark! No, the house is still! It's a Doctor's Dream! [*Punch*, Jan. 20, '83.]

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 5 TO FEBRUARY 12, 1883.

TOWN, FRANCIS L., *Major and Surgeon.*—Is relieved from duty at Fort Walla Walla, and will report to the commanding officer, Vancouver Barracks, for duty as Post Surgeon.—*S. O. 7, Department of the Columbia, January 27*, 1883.

WOODWARD, J. J., *Major and Surgeon*.—The extension of leave of absence on account of sickness granted October 6, 1882, is further extended six months on account of sickness.—*Par. 9, S. O. 34, A. G. O., February 9*, 1883.

DE LOFFRE, AUGUSTUS A., *Captain and Assistant Surgeon.*—Relieved from further duty in this Department.—*S. O. 28, Department of the Missouri, February 5*, 1883.

TAYLOR, MARCUS E., *Captain and Assistant Surgeon.*—So much of S. O. 20, A. G. O., January 24, 1883, as directs him to report in person to the commanding general, Department of the East, is amended to direct him to report in person to the commanding officer, David's Island, New York Harbor, for duty at that station.—*Par. 2, S. O. 33, A. G. O., February 8*, 1883.

TAYLOR, B. D., *Captain and Assistant Surgeon.*—Granted leave of absence for one month, on surgeon's certificate of disability.—*Par. 2, S. O. 13, Department of Texas, Feb. 1*, 1883.

NEWTON, R. C., *First Lieutenant and Assistant Surgeon.*—Is relieved from duty at Fort Cummings, New Mexico, and will proceed to Fort Sill, Indian Territory, and report to the commanding officer for duty.—*S. O. 28, Department of the Missouri, February 5*, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

PLASTER-OF-PARIS DRESSING IN INJURY TO THE ELBOW-JOINT.

Abstract of a Clinical Lecture delivered

BY PROF. JAMES L. LITTLE, M.D.,

IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

GENTLEMEN: The patient that I now show you is a boy of about ten years of age, brought here by Dr. Griswold, of this city. He sustained an injury to his elbow, which has resulted in an inflammation of the joint of a subacute character. Dr. Griswold tells me that when he saw the case, some four weeks ago, he detected marked fluctuation upon the outer side of the joint. With the aspirator he removed about two ounces of pus. Probably you remember that I presented this case to you a week ago. I then detected fluctuation over the seat of the former abscess, and naturally concluded that it was refilling. At that time, as you will remember, I applied a plaster-of-Paris splint to the arm and forearm without altering its position, the idea being to keep the joint at rest. I told you that I would come to-day prepared to anæsthetize the patient and bring his arm into a flexed position, a little less than a right angle, so that if anchylosis resulted the limb would be in a good position for use. It was also my intention, as I told you at that time, to open the abscess, make a thorough examination, under strict antiseptic precautions, and ascertain whether the abscess was connected with the joint, introducing a drainage-tube, if necessary, and dressing the part according to Lister. But you see that the general condition of the patient is very much improved. Upon examination I find that the swelling around the elbow has entirely disappeared, so that no fluctuation can now be detected. No operative interference, therefore, will be necessary, so far as the abscess is concerned. I wish, however, to put the arm in such a position that, should the joint become stiffened, the limb will be of some service to the patient. To this end the boy has been thoroughly anæsthetized, and I now forcibly flex the arm to a little less than a right angle, so that the hand touches the mouth. While the limb is held in this position I apply a plaster-of-Paris splint to the anterior portion of the arm and forearm. This, as you will see, is made of two thicknesses of bleached canton flannel, wide enough to enclose about one-half of the circumference of the limb. The flannel is thoroughly saturated in a mixture of plaster of Paris and water. A strip of the same material, about an inch and a half in width, saturated in the plaster of Paris, is applied around the arm, just below the upper extremity of the splint, and another similar band above the wrist, to retain the anterior splint in position. While the plaster is still wet, and with the arm held in the desired position by my assistant, Dr. Powell, I apply an ordinary roller bandage tightly from the hand to the shoulder, moulding the flannel to the limb. Having accomplished this, the limb is held in the position in which we have placed it until the plaster is set. This takes but a short time. The plaster is now hard, and I remove the bandage, and, as you see, I have a beautiful plaster-of-Paris anterior splint, which is unyielding, and will hold the arm in its present position. At the same time the dorsal surface of the joint, from the external to the internal condyle, is uncovered, so that its condition can be observed from time to time. A dry cotton roller is now applied from the hand to the shoulder, and the dressing is complete, and its appearance is shown in the following figure.

With plaster applied in this way you can make an angular splint to cover any part of the forearm or arm. This dressing has one advantage over all others, inasmuch as after its application the limb can at once be placed in the desired position and held there until the dressing becomes hard. Another advantage is that it can be applied directly to the skin without any irritation resulting. If hairs exist upon the limb, the surface should be smeared with oil or vaseline before applying the splint.

The length of time that I shall allow this dressing to remain upon the patient will depend upon the progress of the case. If the inflammation subsides rapidly, and the pain disappears, it can be removed in a short time and passive motion begun.

ORIGINAL ARTICLES.

A PARTIAL STUDY OF THE POISON OF HELODERMA SUSPECTUM (COPE)—THE GILA MONSTER.

BY S. WEIR MITCHELL, M.D., AND EDWARD T. REICHERT, M.D.,

OF PHILADELPHIA.

(*Read before the College of Physicians of Philadelphia, February 7, 1883.*)

FOR some years past it has been known to naturalists that the Gila lizard of Arizona and Sonora was endowed with anterior deciduous grooved teeth, which communicated by ducts with large glands within the angle of the lower jaw. These arrangements naturally suggested a certain power of poisoning, as to which, however, the most conflicting accounts have reached, and continue to reach us from Arizona. In many houses the sluggish creature shown to you was a pet of children, and seems to have been averse to using his weapons of offence. The occasional accidents from his bite were variously explained away; but still, among the Indians and some settlers, he enjoyed an evil reputation. Only within a week we have had two letters from Arizona, the one describing him as "more peaceful and harmless than a young missionary," and

the other as being "worse than a whole apothecary shop." Nevertheless, both in France, and of late in London, specimens have bitten and promptly killed small animals.

It is worth while to mention more distinctly some of the evidence for and against the poisoning power of Heloderma. His bad name in Mexico is mentioned by Bocourt and Dumerei, but Sumichrast is more full in his statements.

This curious lizard is, he says, slow and embarrassed in his movements, and hides in the daylight, and especially in dry weather, to emerge at night and in wet seasons. He is said to smell ill, in fact to be of a nauseating odor, and is described as slobbering forth a sticky, whitish saliva when irritated. The natives, says Sumichrast, hold him in the utmost terror, and consider him as more fatal than any serpent. When made to bite a fowl, it died in twelve hours, with bloody fluid exuding from its mouth, the wound being of a purple tint. A cat bitten was very ill, but recovered, remaining thin and weak. The Heloderma horridum sent to London, to Sir John Lubbock, killed a frog in a few minutes, and a guinea-pig in three minutes.

Many years ago Dr. Irwin,[1] U. S. A., experimented in New Mexico with the Gila monster, and concluded it to be harmless, while Mr. Horan, Superintendent of the National Museum, says he himself has been several times bitten without serious results. The following statement of Dr. Shufeldt adds a further difficulty in making up our estimate of the powers of Heloderma. The lizard he speaks of is the one we now exhibit. (The lizard was now shown.) It was sent to the Smithsonian by A. T. Burr, U. S. A., and is the H. suspectum of Cope.

On the 18th inst., in the company of Professor Gill of the Smithsonian Institution, I examined for the first time Dr. Burr's specimen, then in a cage in the herpetological room, It was in capital health, and at first I handled it with great care, holding it in my left hand, examining special parts with my right. A the close of this examination I was about to return the fellow to his temporary quarters, when my left hand slipped slightly, and the now highly indignant and irritated Heloderma made a dart forward and seized my right thumb in his mouth, inflicting a severe lacerated wound, sinking the teeth in his upper maxilla to the very bone. He loosed his hold immediately and I replaced him in his cage, with far greater haste, perhaps, than I removed him from it.

By suction with my mouth, I drew not a little blood from the wound, but the bleeding soon ceased entirely, to be followed in a few moments by very severe shooting pains up my arm and down the corresponding side. The severity of these pains was so unexpected that, added to the nervous shock already experienced, no doubt, and a rapid swelling of the parts that now set in, caused me to become so faint as to fall, and Dr. Gill's study was reached with no little difficulty. The action of the skin was greatly increased, and the perspiration flowed profusely. A small quantity of whiskey was administered. This is about a fair statement of the immediate symptoms; the same night the pain allowed of no rest, although the hand was kept in ice and laudanum: but the swelling was confined to this member alone, not passing beyond the wrist. Next morning this was considerably reduced, and further reduction was assisted by the use of a lead-water wash.

In a few days the wound healed kindly, and in all probability will leave no scar; all other symptoms subsided without treatment, beyond the wearing for forty-eight hours so much of a kid glove as covered the parts involved.

After the bite our specimen was dull and sluggish, simulating the torpidity of the venomous serpent after it has inflicted its deadly wound, but it soon resumed its usual action and appearance, crawling in rather an awkward manner about its cage.—*American Naturalist*, November, 1882.

The specimen shown has eaten once since we have had him, but the Gila monster is said to live on bird eggs, and to eat daily of like food while in captivity.

The sluggish habits ascribed to Heloderma in general have been noticed in our specimen; but it is clear from Dr. Shufeldt's accident that, like the habitually inert Crotalidæ, this creature is capable of sudden, and therefore unexpected, agility in attack.

As we shall have sent to us in the spring a number of Helodermas, we shall then be able to complete the study of the poison of these interesting lizards—the only members of the family of lizards as yet known to be poisonous. The subject is, however, too full of interest to delay the publication of our preliminary study, since, as far as it has gone, it is perfectly definite and satisfactory.

The Gila monster inhabits the dry hillsides of Arizona, and is said to reach the length of three feet. The specimen we exhibit is about fourteen inches long, and from war or accident had when he reached us lost all but two of his teeth, and as yet no new ones have taken their places. Without them he would certainly be as harmless as a rattlesnake deprived of his fangs; and as these teeth are very small, and easily removed, their absence may account for some of the instances in which the lizard has bitten and done no grave harm.

Experiments made in the usual vague way, by allowing the lizard to bite animals, are obviously untrustworthy; so that it was thought best to use the saliva in known quantities. The fluid was obtained by provoking the animal to bite on a saucer-edge—which it was most indisposed to do. When once it had seized the saucer it was hard to pull it away, so powerful was the grip of the lizard's jaws. After a moment, a thin fluid like saliva dripped in small quantities from the lower jaw. It was slightly tinted with blood, due to the violence of the bite, and it had a faint and not unpleasantly aromatic odor. The secretion thus collected from the mouth was distinctly alkaline, in contrast to serpent venoms, which are all alike acid.

Experiment I.—About four minims were diluted with one-half cubic centimetre of water, and thrown into the breast muscles of a large, strong pigeon, at

4.23 P.M. In three minutes the pigeon was rocking on its feet, and walking unsteadily. At the same time the respiration became rapid and short, and at the fifth minute feeble. At the sixth minute the bird fell in convulsions, with dilated pupils, and was dead before the end of the seventh minute.

[1] Am. Naturalist, November, 1882.

The first contrast to the effects of venom was shown when the wound made by the hypodermic needle was examined. There was not the least trace of local action, such as is so characteristic of the bite of serpents, and especially of the Crotalidæ.

The muscles and nerves responded perfectly to weak induced currents, and to mechanical stimuli.

The heart was arrested in the fullest diastole, and was full of firm black clots. The intestines looked congested. The spine was not examined.

Experiment II.—In the following experiment a full-grown etherized rabbit was used, and the left carotid being connected with the Kymographion, one-sixth of a grain of dry Heloderma venom dissolved in one cc. of distilled water, was injected into the external jugular vein.

	1.00	52	.3	
	1.30			
	1.35	Violent convulsions.		

The animal died in convulsions with dilated pupils.

The results were identical with those obtained when the pneumogastrics were entire, so that the effect on the heart is direct, and not by inhibition through the pneumogastrics.

The results of the autopsy in both of the above experiments are identical, and may be summed up as follows:

Autopsy, made immediately after death.—Heart arrested in diastole; heart does not react to induction currents; muscles everywhere respond to electric stimulation; motor nerves intact; cord unirritable, and will not respond to the strongest current produced by one large gravity cell, with Du Bois Reymond's induction coil; bowels still irritable; peristaltic movements occur spontaneously; the intestines are natural in color, as are all other organs. After five minutes the heart began to contract, and was finally found in a systolic condition. The interior of the organ was full of black clots, especially the auricles, the left ventricle containing but a very small clot.

In order still further to determine the effect on the heart, the following experiments were made:

Experiment IV.—

hrs. min.	
7.33	Pithed frog and exposed the heart.
.52	Heart beats 21 in 30 seconds.
.52½	Placed a small portion of dried venom of Heloderma on the heart.
.56	Heart beats 20 in 30 seconds.
8.05	" " 19 " "
.18	" " 18 " "
.30	" " 15 " "
.43	" " 14 " "
.55	" " 10 " "
9.30	" " ceased.

Experiment V.—

hrs. min.	
8.05	Took two "cut-out" hearts of frogs, and placed them in a normal salt solution in separate vessels, just sufficient liquid being used to cover the hearts. On one heart was placed a small quantity of dried venom.
.27	The poisoned heart beats more feebly than the other.
.30	" " " " still more feebly than the other, which is yet firm.
.45	The poisoned heart stopped beating, the other beats firmly.
.55	The poisoned heart stopped beating, the other beats firmly but slower.

Experiment VI.—

3.45	Exposed the hearts of two pithed frogs.
4.00	Placed on one some dried venom.
.30	The poisoned heart beats are decidedly feebler than the other.
.50	The poisoned heart beats more feebly; the unpoisoned heart beats firmly and apparently in a normal manner.
6.00	The poisoned heart beats very feebly and does not fill with blood. The normal heart beats firmly, and fills well with blood at each beat, making a striking contrast with the poisoned heart.

We may conclude that—

The poison of Heloderma causes no local injury.

That it arrests the heart in diastole, and that the organ afterwards contracts slowly—possibly in rapid rigor mortis.

That the cardiac muscle loses its irritability to stimuli at the time it ceases to beat.

That the other muscles and the nerves respond readily to irritants.

That the spinal cord has its power annihilated abruptly, and refuses to respond to the most powerful electrical currents.

This interesting and virulent heart poison contrasts strongly with the venoms of serpents, since they give rise to local hemorrhages, and cause death chiefly through failure of the respiration, and not by the heart, unless given in overwhelming doses.

They lower muscle and nerve reactions, especially those of the respiratory apparatus, but do not, as a rule, cause extreme and abrupt loss of spinal power.

Finally, they give rise to a wide range of secondary pathological appearances, which are absent from Heloderma poisoning.

There remains on our minds no doubt as to the fact that the fluid which drips from the mouth of Heloderma when it bites is a very active poison. The present study is, however, limited in range, and we cannot yet feel sure that the fluid in question comes from the glands now presumed from their relation to the teeth to be poisonous.

The briefest examination of the lizard's anatomy makes clear why it has been with reason suspected to be poisonous, and why it poisons with so much difficulty. Unless the teeth are entire, the poison abundant, and the teeth buried in the bitten flesh so as to force it down into contact with the ducts where they open at the crown of the teeth, it is hard to see how even a drop of poison could be forced into the wounds. Yet it is certain that small animals may die from the bite, and this may be due to the extraordinary activity of the poison, and to the lizard's habit of tenaciously holding fast to what it bites, so as to allow time for a certain amount of absorption.

It is plain enough that a lizard as small as the one exhibited would be very unlikely to inflict a wound fatal to man; but it is possible that the larger animal—and it is said to reach a length of three feet—might prove a more efficient poisoner.

We are unwilling to drop the subject without a few words as to the nature of this poison.

The recent researches of Dr. Sternberg and Prof. Gautier have shown that human saliva may kill a rabbit in twenty-four hours, according to the former observer, and a pigeon in a few hours, he does not say how many, according to the latter, if a quantity of saliva have been concentrated by heat and so used. Professor Gautier thinks the saliva and all venoms owe, at least, a part of their power to normal ptomaines or animal alkaloids, the products of putrefactive processes, and recalls to us the fact that most secretions are measurably poisonous.

The answer to these views we shall have to consider elsewhere, and at length, but it will be sufficient here to say that there is no resemblance between the symptoms caused by the known ptomaines and those produced by any of the venoms. When it was shown that healthy human saliva was competent to kill, it was natural enough to leap to the conclusion that the venoms were merely concentrated salivas. The analogy ends with the fact that both may cause death, but the one may kill in twenty seconds, and the other requires, at the least, many hours, whilst also it seems, as regards saliva, to be, in some degree, a question of the toxic activity of certain individuals, not all being so uncomfortably endowed as Dr. Sternberg himself.

A CASE OF ACUTE ARTICULAR RHEUMATISM IN A CHILD.

BY WEBSTER S. SMITH, M.D.,
OF WEST MILTON, OHIO.

THE occurrence of acute articular rheumatism in infants and young children has been admitted by some medical writers and denied by others. Senator says, "Children under four are scarcely ever affected;" Bristowe, "Young infants scarcely, if ever, are attacked;" and Bartholow, "Rarely occurring before seven."

The following case will, no doubt, be of some interest on this disputed question.

On October 7, 1882, Mrs. B., called at our office with her boy, aged two and a half years. She stated that on Oct. 5 he had a severe chill, followed by fever and profuse sweating. The next day she thought the symptoms had somewhat subsided, and child better; but on the morning of the 7th the child seemed worse, and she gave him a dose of castor oil, which operated without affording relief. Dr. Pearson, my associate, prescribed for the child antiperiodic doses of quinine in solution with aromatic syrup of rhubarb.

Oct. 10.—Dr. Pearson found the child with a temperature of 104½°, pulse 150, tongue badly coated, sweating profusely, and on the verge of convulsions. Prescribed aconite and bromide of

potassium. 7 P. M., temperature 104°; the nervous symptoms somewhat abated.

11th.—7 A. M., temp. 103°; and, for the first time, the knee-joint was observed to be swollen, hot, and very painful when moved—the child crying out even from the weight of the bed-clothes. In the afternoon I found the child with the left limb semi-flexed, and his head buried in the pillows, resting almost the whole weight of his body on his head and heels, screaming out every time his hips or the inflamed joint were moved; temperature was somewhat lower, and pulse strong, frequent, and regular. Ordered hot fomentations to the knee-joint, and continued treatment.

12th.—Dr. Pearson observed irregularity of the pulse; temp. 102°; slight delirium on wakening; knee-joint still swollen, and exceedingly painful. In the afternoon I saw the case with Dr. Pearson: child very drowsy, pulse irregular, respirations hurried and spasmodic, and inequality of the pupils, but *no* deafness, squinting, nor intolerance of light and sound. A bronchitis was beginning to develop, with a dry, hacking cough. Dr. Baker saw the case in consultation, and agreed in our diagnosis of acute articular rheumatism. Prescribed the following:

℞.—Acidi salicylici,
Sodæ bicarbonatis, . . . āā ʒj.
Aquæ cinnamomi,
Aquæ, ... āā ʒj.—M.

Of which the child was to take a teaspoonful every hour; placed a narrow blister over cervical region of spine, and also blisters over knee and hip-joint. Prescribed small doses of tinct. belladonnæ for irregularity of pulse.

13th.—Dr. Pearson and I saw the case together: slight irregularity of pulse, temp. 101½°, no inequality of pupils, tongue badly coated, but general condition of child improved. Continued treatment, and added small doses of calomel every hour.

14th —Passed a restless night; pulse 128, temp. 101°; left off calomel, and continued previous treatment.

15th.—Pulse 120, temp. 100¼°; better; herpes around the lips, and mouth very sore; bowels moved twice during the night. Discontinued salicylic acid, and prescribed chlorate of potash for the mouth.

16th.—Worse; right temporo-maxillary articulation became involved during the night, and was considerably swollen by morning; complained of pain in the phalangeal articulations, but able to move the inflamed hip and knee-joint freely without pain; temp. 103¾°. Prescribed salicylic acid treatment again.

17th.—Passed a very restless night; grasps his jaw with his hand; pulse 140, and regular; temp. 102°; sleeping quietly this morning; taking milk-toast freely for nourishment; temporo-maxillary, the only articulation complained of. Ordered hot fomentations to jaw, in addition to the salicylic acid treatment.

18th.—Temp. 103½°; bowels loose; slept well during the night and complained very little of pain in the joints; some tenderness over the bowels; mouth very sore; left off salicylic acid and gave Dover powder and bismuth every two hours.

19th.—Temp. at 10 A.M., 101½°; pulse 150, regular, but weak; bowels loose; complains occasionally of pain in knee-joint; lies with head thrown back; drank considerable milk this morning.

20th.—Temp. 99½°; passed a very restless night; diarrhœa persists; taking milk freely.

21st.—Temp. 100½°; diarrhœa still continues; complains of pain in cervical region; head thrown far back; no trouble in other joints; pulse 140, regular and weak; prescribed bismuth.

22d.—Temp. normal; lips very sore; prescribed tar ointment.

23d.—Temp. at 8 P. M., 102½°; humero-scapular articulation involved; great pain on movement of this joint; lips better; diarrhœa better; pulse regular but weak; prescribed aconite and bismuth every two hours.

24th.—Tem. 9 A. M., 101½°; pain in left shoulder; treatment continued.

25th.—Dr. Pearson called in the evening and found fever rising, but did not take temperature owing to restlessness of patient; pain in knee very severe; he prescribed Dover powder, aconite, and hot fomentations.

26th.—I called in the morning and found temperature 103¼°; pulse full, strong, and rapid; bowels regular; prescribed drop doses of aconite every two hours; ordered patient to be sponged off at 4 P. M.; found child very nervous; temperature still high, ordered bromide of potash. At evening visit child had choreic symptoms; impossible to feel pulse owing to motion of arm; tongue convulsed; movements of muscles of the face.

28th.—I was called hurriedly to see child; found abdomen distended and tympanitic; child having choreic movements of face and upper limbs; temperature 101¾°; pupils dilated; passages frequent and very offensive; pain over abdomen; ordered bromide of potash, Dover powder, brandy, and hot fomentations to abdomen.

29th.—Abdomen softer; passages normal; choreic movements continued, but patient better.

30th.—P. M., temp. 103½°; other symptoms better; child very drowsy.

31st.—A. M., temp. 104¾°; very dull and restless; prescribed a large dose of quinine to reduce fever; in afternoon child went into coma, from which it did not arouse until November 1, and then took small amount of brandy.

Nov. 1.—Temp. 102½°; child in coma.

2d.—Coma continues; died at 3 P.M.

There was some difficulty in making a diagnosis of the case in the start, the knee-joint symptoms not manifesting themselves until October 11. The remission of symptoms, October 6, led us to look at first at the case as one of intermittent trouble. Also the condition of opisthotonos led us to consider cerebro-spinal meningitis in making our diagnosis.

The diagnostic provings we would get, after looking at the history of the case, would be these: the frequent high temperature, the number of joints in-

volved, the pericarditis, and the choreic symptoms following in the latter part of the disease.

Salicylic acid was given and discontinued several times during the case, owing to the severe symptoms it produced on the mucous membranes.

Since reading an article in the October number of the *American Journal of the Medical Sciences*, on "Rheumatic Leucoinoitis," by Dr. Buckler, of Paris, considerable interest attaches to the case in regard to the bronchitic symptoms. These attacks were fleeting, for instance, that of October 12, in which, I have no doubt, the white fibrous tissue under the mucous membrane of the bronchial tubes was the seat of the rheumatic trouble.

The death was due to hyperpyrexia and coma, a fatal termination of the disease according to Bartholow.

HOSPITAL NOTES.

BOSTON CITY HOSPITAL.

(Service of C. D. HOMANS, M.D.)

EXCISION OF BONES OF THE FOOT; IODOFORM POISONING.

(Reported by ROYAL WHITMAN, M.D., House Surgeon.)

THE patient, an anæmic girl, 20 years of age, entered the hospital May 16, 1882, and gave the following history:

One year before, she had sprained her left ankle. The accident was followed by pain, swelling, and stiffness in the joint, which confined her to the house for five weeks, and since then she has been unable to walk without the aid of a crutch. About one month before her entrance into the hospital the ankle began to swell, and she noticed that the foot was slightly displaced outwards.

The examination showed the following condition:

The left foot was slightly everted and displaced outwards, and over the inner malleolus was a prominent swelling, fluctuating and tender on pressure, about two inches long and one inch in diameter. There was some stiffness about the ankle-joint, and motion was slightly painful. The fluctuating point was incised, and a considerable quantity of pus was evacuated. No dead bone was discovered, and splints and poultices were applied. The joint, however, gradually became more swollen and painful, and the patient began to show signs of constitutional disturbance.

June 2.—Incisions were made upon either side of the joint, and extensive disease of the bones was discovered. A horse-hair drain was then passed between the astragalus and os calcis. During the two following weeks the pain became more severe, and the patient rapidly grew worse; and on June 23, the patient having refused amputation, Dr. Homans decided to attempt to remove all the diseased bone.

The patient was etherized and the former incisions upon each side of the joint were enlarged. The astragulus was then removed entire. The os calcis, which was also in a soft, carious state, was then removed, with the exception of about three-fourths of an inch of the posterior portion to which the tendo Achillis is attached, from which the body of the bone was removed with the chain-saw.

Nearly all of the tarsal bones, which were almost universally diseased, were removed with the bone forceps. The disease had not apparently affected the lower surface of the tibia or the metatarsal bones. The immense cavity was then packed with carbolized sponges, and the collapsed foot brought up into fair shape and splints were applied. After the operation, the pain, which had been severe, was entirely relieved.

27th.—The leg was placed in a plaster splint, with openings on either side, and the cavity of the wound was packed with iodoform and absorbent cotton, which was allowed to remain for two days.

On the 29th inst., it was noticed that the patient seemed somewhat drowsy. She suffered no pain, and healthy granulations were springing up from all sides of the cavity.

30th.—The drowsiness increased, and the patient seemed somewhat stupid. There was no pain or rise in temperature or pulse.

July 1.—Patient remained in about the same condition.

2d.—The patient continued in the same drowsy, stupid condition, but was also at times hysterical and slightly delirious. The iodoform was removed, and the wound carefully cleaned and dressed with chlorinated soda wash.

3d.—The patient was drowsy during the day, but violently delirious during the night.

4th.—This condition gradually passed off. After this her symptoms progressed favorably.

20th.—The cavity had been nearly closed by granulations, and the external wounds had commenced to cicatrize.

August 1.—The patient could support the foot, which had retained nearly the original shape. The external wounds were slowly cicatrizing, and there was but a moderate amount of purulent discharge. A few fragments of necrosed bone could be felt. There was but little pain, and the patient's condition was good.

25th.—Though the patient was progressing as favorably as could have been expected, yet she decided that she could not remain an invalid for the six months or a year necessary for her recovery, and insisted upon having the leg amputated, which was accordingly done by Dr. Thorndike, at the junction of the middle and lower third.

An examination showed but little evidence of disease in the foot. The tibia and fibula were in close contact with the fragments of the tarsal bones, and of the os calcis, and a variety of false joint had formed, showing the possibility of a recovery after such an extensive removal of diseased bone. The patient rapidly recovered, and was discharged October 5th.

There has been one other case of suspected iodoform poisoning at the hospital. It occurred in the case of a boy on whom an operation for the removal of necrosed bone from the tibia had been performed. The resulting cavity, which would contain, perhaps, one-half drachm, was packed with iodoform, which was allowed to remain as a permanent dressing. In about two weeks after its introduction, it was noticed that the boy was becoming drowsy, falling asleep at all hours. Otherwise his condition was good. The iodoform was removed, and this condition passed off.

Though a large quantity of iodoform has been used at the hospital during the past year, these are the only cases in which any symptoms of poisoning have been noticed.

MEDICAL PROGRESS.

A CASE OF EXTIRPATION OF THE LARYNX.—DR. KARL MAYDL reports a successful case of extirpation of the larynx, performed in Prof. Albert's clinic, in Vienna, on a man, aged fifty years, for an extensive carcinomatous tumor of the larynx which interfered with respiration and deglutition. Trachëotomy was first performed, and Trendelenburg's canula introduced and allowed to remain for three days. Recovery

rapidly occurred and an artificial larynx was inserted. —*Wiener Med. Presse*, December 31, 1882.

PARACENTESIS PERICARDII.—A case of acute pericarditis with effusion, occurred in the Leeds Infirmary, under the care of DR. CLIFFORD ALLBUTT, for which paracentesis was performed, about one ounce of bloody serum being removed; recovery took place. The drugs employed in the case were various, and given, with the exception of salicylate of sodium, rather with the idea of combating the tendency to death than with any specific notion, and consequently have not been noted. It may be well to note that blistering was discarded. Among the many points of interest in the case, the following may be specially noted: 1. The rather doubtful rheumatic nature of the case at the commencement, and the failure of salicylate of sodium to relieve. 2. The total absence of all joint affections, assuming it to have been a case of rheumatic fever. 3. A point so difficult to display in the notes, but so obvious to all who saw the case from day to day; the rapidly downward course of the case immediately prior to the aspiration, and the unaided part the operation played in saving life. 4. The comparatively rapid absorption of the effusion after the withdrawal of so small a portion of it.—*Lancet*, January 27, 1883.

MYXŒDEMA.—M. GUERLAIN has observed a remarkable case of myxœdema, or pachydermatous cachexia, supervening on a wound of the neck. M. Verneuil points out that the nervous nature of this affection now appears to be clearly demonstrated; and that it is perfectly admissible that, in the case above referred to, as in many other diseases, the wound may have an influence on the central nervous system capable of bringing on special phenomena.—*British Medical Journal*, February 3, 1883.

COMPRESSION OF THE AORTA IN POST-PARTUM UTERINE HEMORRHAGE.—DR. WILMART, of Brussels, relates, in the *Presse Méd. Belge*, a case of atonic uterus in which, after the rapid completion of delivery by the forceps, alarming uterine hemorrhage set in, which reduced the patient to a moribund state. Having administered ergot in vain, he had recourse to the application of pressure by means of the fingers between the third and fourth lumbar vertebræ, the patient being placed in a position with her head downwards and her feet uppermost. The compression of the aorta had to be maintained for a long period, every removal of the fingers being attended by a recurrence of the hemorrhage; but eventually the compression, aided by ergot and brandy, proved completely successful. Dr. Wilmart observes that few know the difficulty and pain caused to the operator while making this compression for a a sufficiently long time, especially, as in his case, where there is no assistant at hand.—*Med. Times and Gazette*, February 3, 1883.

CARBAMIDE AS A SUBSTITUTE FOR QUININE.—The *Journal d'Hygiene* learns from Gen. Kokhowski that DR. BELVOUSOFF has discovered an efficient successor for quinine. Belvousoff, Prosector of the University of Kharkoff, presented his memoir before the Russian Commission of Hygiene on the 5th of October last, recommending carbamide, the rational formula of which is

$$\left.\begin{matrix} CO \\ H_2 \\ H_2 \end{matrix}\right\} N_2,$$

as the substitute for quinine.

From experiments made in the hospitals, the following results were obtained: 1. That in cases of intermittent fever carbamide acts as a specific. 2. That this remedy can be employed in many other complaints to reduce the temperature of the patient; it is, moreover, without taste, and does not depress the nervous system.

This action of carbamide is easily understood in the light of the latest researches on uræmia. It is also well known that in southern Russia and Montenegro the peasantry are accustomed to cure themselves of intermittent fevers by the use of urine as a medicine.

Belvousoff has also shown that carbamide instantly kills the lower organisms, such as bacteria and vibriones, just as quinine does.

From an economical point of view, says the writer, the discovery is very important, as carbamide is much cheaper than quinine.

[Carbamide, or *urea*, can be obtained from urine, but is usually made by the action of cyanate of potash on sulphate of ammonia.]—*Scientific American*, Feb. 10, 1883.

THE EXPLORATION OF THE BLADDER BY PERINEAL SECTION.—At the meeting of the Royal Medical and Chirurgical Society, held January 23, 1883, SIR HENRY THOMPSON asked attention to a new method of investigating obscure diseases of the bladder, which promised to be valuable in certain conditions occasionally met with. Every one sometimes meets with a case in which the symptoms of vesical disease are severe and obstinate; and, although very careful examination is made, is unable to arrive at a rational diagnosis. The occurrence is, doubtless, not a common one; in the great majority of cases, carefully made observations demonstrate the nature and seat of the disease. But for the exceptional cases, always important—cases generally marked by frequent or persisting hæmaturia of some standing, manifestly not renal, and without local sign of cancerous tumor—he proposed to take decided action, and to submit, further, that such action should not be unduly postponed. The essential step in the method proposed was to examine the entire internal surface of the bladder with the finger, by which means we can recognize the presence of any tumor, large or small, the existence of encysted calculus, etc. The method of doing this he illustrated, and showed it to be a proceeding simple and easy of performance, and at the same time one which involved little, if any, danger to life. It consisted in making a small opening from the raphé of the perineum to the membranous urethra, which was opened on a grooved staff, just enough to admit the left index finger to enter the canal and to be pushed on to the neck of the bladder. Provided the anæsthesia of the patient was so complete that the abdominal muscles were perfectly relaxed, every portion of the internal surface of the bladder might be brought consecutively by suprapubic pressure into close contact with the tip of the finger, and any deviation from the natural condition, however slight, might be noted. The operation was an external urethrotomy only, and involved neither the prostate nor the bladder. The application of the proceeding, not only to diagnosis, but subsequently to treatment, was then discussed. It was shown to offer facility for the removal of tumors, impacted calculus, etc. Seven or eight cases in which the operation had been performed were cited, and several examples of tumor were exhibited which had been removed by the author. These latter were examples of a disease which was inevitably fatal unless removed by operation. The signs and symptoms of their presence were discussed; great care was necessary in examining the state of the patients before having recourse to operation. The two conditions, the absence of which it was important to be assured of before interfering, were renal disease and cancer.

Hæmaturia from either of these sources of course absolutely contraindicated an operation.—*British Med. Journal*, January 27, 1883.

INTRA-UTERINE STRANGULATION OF A FŒTUS BY ITS OWN UMBILICAL CORD.—In the *Centralblatt für Gynäkologie*, January 20, 1883, DR. E. FRAENKEL reports the case of a woman who was delivered of twins, one living, and the other dead and in a macerated condition, the death evidently having been produced by compression of the umbilical cord, which was twisted five times tightly around its neck and separated from its placenta.

DETECTION OF BACILLI IN THE BREATH OF TUBERCULOUS PATIENTS.—By the following simple method, DR. R. CHARNLEY SMITH has succeeded in demonstrating with facility the presence of the bacilli of tubercle in the breath of patients suffering from true tubercular phthisis. For which purpose, he allows the patient to breathe, at frequent intervals during the day, through two thin sheets of pyroxyline or gun-cotton, one layer in front of the other, and both of which are placed in the outer compartment of an ordinary "pepper duster" respirator. The cotton when so arranged will act as a double filter—the external layer removing from the in-going air all the suspended particles, such as dust, micro-fungi, starch, etc., which are always more or less present in it, and which it is desirable to exclude; the internal layer retaining only those particles which come from the lungs—viz., micrococci, bacilli, and some epithelial scales. It is, therefore, in the layer which has been next to the mouth of the patient that he seeks for the bacilli peculiar to this disease. This he does by converting the pyroxyline into collodion by dissolving the former in a mixture of rectified spirit and ether. By this means the whole of the cotton fibre dissolves, but the organisms which have been emitted from the lungs are unacted on by this menstruum, and remain suspended in it, but not visible to the naked eye.

To render the bacilli manifest, his plan is to pour the thin collodion thus formed on a microscope slide and allow the fluid to run uniformly over the surface of the glass, then immediately to turn the glass on one of its edges, that only the merest film of collodion may remain on the glass. The thinner the film produced the more successful will the experiment be. The film is then to be stained. This may be done by one of the methods now well known to the profession, such as that of Ehrlich or of Heneage Gibbes.—*Lancet*, Jan. 20, 1883.

RETENTION OF A DETRUNCATED HEAD AND THE PLACENTA IN UTERO FOR FORTY DAYS.—This astonishing case is reported in a recent number of the *Archiv für Gynäkologie* by DR. ALOIS VALENTA. The patient was thirty-five years old, and this was her fourth child. Labor came on at term, the child presenting with the shoulder. A medical man was called, who proceeded first to detach the lowermost arm, and then to bring down the feet. He delivered the body, but could not get the head to follow, so he cut through the neck and left the head behind. Two other doctors were then called in, but all they did was to administer ergot and advise that the patient should be taken to a hospital. This her husband would not hear of, and so nothing was done. Eight days after the medical men had seen her, a midwife was called in; but she did nothing except syringe the vagina with warm water every two or three days. The patient all the time had no bad symptoms—no rigor, no particular pain, no bladder or rectum trouble, ate well, and slept well; the only thing was that she felt weak, and that the lochia stank insufferably. Thirty-eight days after the labor the patient rebelled against marital authority, and had herself taken to the hospital. When seen there, her pulse was 72, temperature 99.5°. There was no sign of uterine action, and the uterus seemed to have undergone complete involution, being spread like a thin cap over the retained head. Three days after admission, the vagina having been first repeatedly shringed with a three per cent. solution of carbolic acid, the cervix was dilated with sponge and tupelo tents, and repeated doses of ergot were given. This brought away discharge and small fragments of bone, but the patient felt no pain, although intermittent hardening of the uterus was perceptible. After dilatation, the bones of the fœtal head were seized, as they could be got at, with strong polypus forceps, and carefully removed. The chief difficulty was found with the parietal bones, which were in such close coaptation with the uterine wall that it was difficult to seize them, and when seized, it was necessary to double them up (a thing not easily done) in order to get them through the cervical canal. About forty bits of bone were taken away. Then the placenta, which looked quite fresh, was detached with the finger, and removed piece-meal—a proceeding which occasioned some hemorrhage. The whole operation occupied about an hour and a half. When it was finished, the uterus was washed out with hot water, and ergotine injected subcutaneously. The patient recovered without a bad symptom. Dr. Valenta has only been able to find in literature one case resembling his. This is recorded by Freund. In his case the detached head was retained for ten years, the uterus, as in Valenta's case, showing no inclination to expel it.—*Med. Times and Gazette*, Feb. 3, 1883.

THE BACILLUS OF TUBERCLE.—For several months DR. G. A. HERON has been studying the clinical and diagnostic applications of Koch's discovery of the bacillus of tubercle, and from his experience of sixty-two cases of phthisis of both sexes and of various ages, in which he was able sooner or later to detect it, he has come to the conclusion that such observations are of the highest value both in diagnosis and prognosis, apart from their pathological interest and bearings on public hygiene. Not only are the bacilli absent from those cases of chronic catarrh, emphysema, bronchiectasis, etc., which closest approach to tubercular phthisis, and always present in tubercular cases, but the number—*e. g.*, from three or four to thirty or fifty in a field—bears a direct proportion to the probable rapidity of the course of the disease to a fatal termination. The worst cases are those in which the bacilli are grouped in dense masses. Koch has found that the dried sputa from a hospital floor were as effective in inducing tubercle in animals when inoculated as were fresh sputa, and though hereditary and other conditions may play a part in the propagation of phthisis, there can be little doubt of its infective character in the light of recent discoveries.—*Med. Times and Gazette*, February 3, 1883.

THE ACID OF THE GASTRIC JUICE.—DR. V. POULET has made a large number of experiments on the gastric juice of different species of animals subjected to dialysis, and claims that the principal acid of this fluid is neither lactic nor hydrochloric acid, but hippuric acid in the form of acid hippurate of potassium, combined with neutral phosphates of lime and sodium. The author bases this opinion on the microscopic appearance of the crystals and on the fact that when gastric juice is subjected to dialysis, evaporated at 120° C. to a syrupy consistence, and then treated with an excess of caustic potash or quicklime, the characteristic odor of benzine may be recognized on dry distillation.—*Journ. de Méd. de Paris*, January 27, 1883.

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, FEBRUARY 24, 1883.

SANITARY CONSTRUCTION OF FOUNDATIONS.

IN the selection of building sites and in the construction of houses, far too little attention is bestowed upon the conditions of the soil and the means of averting the injurious influences arising from a damp and impure state of the ground. It is a well-known fact that all soils, even those of the densest formation, are more or less porous, and are therefore permeable by air and water. It is important to bear in mind that there is a constant circulation of the air beneath the surface of the ground, which depends upon various influences, such as heat, atmospheric pressure, rainfall, force of the winds, etc. The "ground-air," as it has been called, acts as a medium for conveying impurities which exist in the soil, and, in a polluted state, is a prime factor in rendering foundations unhealthy.

At variable depths beneath the surface of the ground, there is a continuous stratum or body of water formed by the saturation of the pores and spaces of the soil, to which the significant name of "ground-water" has been given by German writers. Above the line of saturation or water-level, the soil is simply moist, that is, contains both water and air in variable quantities. A high water-level is the chief cause of dampness of the soil and of the structures above it. There is the greatest difference in soils with respect to their power of absorbing and retaining moisture, and none are entirely without it. The rise and fall of the ground-water, by which the soil is at one time saturated with water and at another exposed in a moist state to the action of the ground-air and heat—conditions favorable to the decomposition of impurities left in the interstices—is now recognized as having an important relationship to the causation of disease, as had been pointed out by Pettenkofer and others. A knowledge of these facts is essential to a clear understanding of the manner in which certain hidden agencies operate in making a foundation unhealthy, and is indispensable in applying the means to counteract their injurious influences.

A damp or water-logged soil is one of the common causes of disease. Its influence upon the causation of consumption, rheumatism, catarrh, and other diseases, is no longer disputed. On the other hand, dry, porous soils are generally considered healthy, but even such soils may be injurious to health on account of the facilities they afford for the free circulation of air from impure sources, and the possibility of such contamination must be considered in constructing the foundation and ground floors.

We know that air is universally present in the soil, and that it is more or less movable. It is still further important to observe that the air in the ground is in intimate relation with the air in the house. During most seasons of the year the current is from the soil to the house. This is particularly the case in seasons when houses are artificially heated. The modern plan of heating buildings by means of fires in the cellar or basement, increases the chances of the escape of ground-air and favors the diffusion of any impurities it may contain throughout the apartments.

The ground-air may become the carrier of noxious elements derived from a polluted condition of the surrounding soil. Some of the common sources of soil-contamination to be guarded against are badly constructed sewers, leaking gas-mains, leaking cesspools, leaking drain-pipes, and slops and other refuse matters thrown upon the surface of the ground. In cities it is frequently the case that houses are built upon "made-ground," which is largely composed of animal and vegetable refuse matter. Under the influence of an active change of air and water, this organic matter undergoes decomposition, the deleterious products of which are imparted to the circumambient air and borne on its current, under circumstances generally present, through the foundations and basement floors of the dwelling.

We have been accustomed to consider soil-pollution more particularly in its relations to contamination of the water-supply, ignoring the fact of its equally intimate relation to a vitiated condition of the ground-air which is in active intercourse with our dwellings. In cities, where wells are rarely depended on for the water-supply, this latter result is most to be dreaded. Pettenkofer complains that we took rather a short-sighted view when we be-

lieved "that the nuisances of our neighbors could only poison the water in our pumps; they can also poison the ground-air for us, and," he remarks, "I see more danger in this, as air is more universally present, and more movable than water."

The selection of a proper site and a careful regard for "cleanliness of the soil and diminution of the organic processes in the ground of dwelling-houses," are the essential requirements to observe in preventing poisoning of the ground-air.

It is not always possible to select a proper site for a dwelling, especially in populous places. Nor is it always within our control to prevent the defilement of the soil and ground-air, even upon our own premises. Hence the necessity of seeking the advice and appliances of the sanitary engineer in the construction of foundations and basement floors to secure an effectual barrier to the ingress of ground-air and all that it portends.

It is humiliating to observe how very little attention, from a sanitary standpoint, is given to the conditions existing beneath the surface of the ground and to the means of excluding ground-air and damp. It is the super-structure, more especially, which claims consideration. And yet, in the construction of houses, there is no more important subject than that relating to the selection of the site and the sanitary arrangement of the details of the foundation.

In selecting a site a great many important factors influence the decision of the question, but when the choice is unrestricted there need be no difficulty in determining it correctly by the aid of the well-defined rules laid down in works on the subject. But it rarely happens that one has the opportunity of selecting a location which possesses every natural advantage; and hence, the necessity of resorting to art to improve the conditions of the soil and avert the injurious influences associated with polluted ground-air and damp. The means of securing these objects are briefly summed up in an article on "damp-proof material" in the *Sanitary Record* of May 15, 1882, which we quote as follows:

1st. Drainage is one of the chief considerations. It has been found that for a building to be hygienic, the subsoil water ought not to be allowed to rise higher than five feet below the foundations. For this purpose, several lines of drain-pipes laid at this level, and discharging into a suitable outlet, are necessary, and these may be constructed in connection with areas round the walls, with a channel for carrying off the water from higher levels.

2d. The most effectual safeguards are, the employment of impervious materials to check the rise of ground-air, such as covering the site with a layer of Portland cement concrete, or with a coating of asphalt.

3d. The use of damp-proof courses in the walls, such as slate, vitrified materials, asphalt, and perforated courses of stoneware, to prevent the rising of moisture in the walls by capillary attraction.

4th. The ventilation of foundations and basements below the ground-floor, which may be effected by raising the ground-floor above the soil, by dry areas round the walls, and by ventilating-bricks.

NEUTRALIZATION OF TUBERCULAR VIRUS.

THE most conclusive evidence as yet adduced in favor of the contagiousness of tuberculosis has recently been brought to the attention of the Academy of Medicine of Paris by DR. VALLIN, in a paper bearing the above title, in which he gave the result of certain experiments having for their object the determination of the effect of disinfecting substances upon the tubercular virus.

To this end, fragments of pulmonary tissue infiltrated with tubercle, and taken from a man dying of phthisis, were bruised in distilled water. This secondary tubercular matter resulting from the inoculation of the first, derived from man, Dr. Vallin used in his experiments. Filtering paper was saturated with the fluid thus obtained, dried, and cut into pieces of equal size. Some intended for control experiments were moistened with pure water, and of the liquid obtained by expression, fifty centigrammes were injected, August 1st, into the peritoneal cavity of healthy guinea-pigs. One was found dead on the 1st of October, in a state of great emaciation. A second was killed November 10th (the 101st day). In both, the liver and spleen were enlarged and very friable, the lungs were stuffed with confluent tubercular masses, in the midst of which the parenchyma of the organ had almost disappeared.

Other pieces of the virulent paper were submitted to the action of various disinfectants: the fumes of sulphurous acid, corrosive sublimate, nitrous acid fumes, etc., before being used for inoculations. In a chamber of fifty cubic centimetres capacity, the little pieces of paper were suspended at the distance of two metres from the floor; the sulphur burned was divided into four separate portions; the chamber was thoroughly closed, and the exposure to the vapor continued twenty-four hours.

The animals inoculated with the paper thus disinfected with quantities of forty and thirty grammes of sulphur, remained uninfected; of two guinea-pigs inoculated with the virulent paper disinfected by twenty grammes of sulphur, in one the abdominal organs were tubercular, while the other remained healthy. With the dose of sulphur at fifteen grammes, a guinea-pig inoculated was found tuberculous throughout; and whenever the quantity of

sulphur burned was less than twenty grammes all the animals were found tuberculous.

Other experiments were made with pieces of paper disinfected with boiling water, which apparently also destroyed the germs, the animals inoculated remaining unharmed. Corrosive sublimate in solutions of the strength of one part in one thousand possessed the same property; so also did nitrous acid.

The important practical deduction from these experiments is that prisons, barracks, hospitals, and schools should be from time to time purified by sulphurous fumigations, which seem at once the most efficient and convenient of the measures employed.

THE TREATMENT OF DETACHMENT OF THE RETINA BY NITRATE OF PILOCARPINE.

The brilliant results which have been attained by the subcutaneous injection of pilocarpine in the treatment of detachment of the retina, are immensely suggestive in respect to the application of this agent for the removal of inflammatory exudations. The strength of the solution employed is one-twentieth, and the dose of each injection is about one-sixth of a grain. The following plan has been found most efficacious: the injections, of the strength above mentioned, are administered in series of ten to fifteen; then a period of repose follows, lasting about eight or ten days, when the injections are resumed again, if necessary. They are usually given in the morning, about two hours after the meal, and inserted at any indifferent point.

The processes which thus go on under our eyes furnish us, in miniature, with a picture of the changes which ensue at any point, the seat of inflammatory exudation. If pilocarpine, when given subcutaneously, at a remote point, can cause the absorption of new material in the eye, will it not accomplish the same results in other tissues? There is here a profitable suggestion. As when exudations occur, the utility of remedies employed against the congestive stage of the inflammatory process ceases, it is, in a high degree, important to be possessed of a remedy which may cause the disintegration and absorption of the new formations. Pilocarpine seems to have this power. Unfortunately, it is so depressing to the vascular system that its use in sufficient quantity is not without danger. It has been used with success to remove pleural exudations, and it may have in the future wider applications in this direction, as we learn how to obviate its depressing effects.

ERGOT IN THE TREATMENT OF TYPHOID FEVER.

We have from time to time noted the novelties of practice in the treatment of typhoid fever, and have published some important practical papers, showing the actual results of special methods. In the *Gazette Hebdomadaire* for January 5, 1883, we find the conclusions to which Dr. Lardier has been conducted by the observation of 73 cases of typhoid fever treated by the administration of some form of ergot. His first conclusion is that ergot is the most efficient remedy which he has hitherto employed in the treatment of typhoid. He rightly insists on the employment of a good preparation. Treated by a suitable form of ergot in good condition, during four years, he was enabled to determine the real value of this remedy in this disease. Of 73 cases treated by ergot in some form, the mortality was 9; in other words, was less than 13 per 100. In these cases there were no intestinal hemorrhages. The good results in this direction were, therefore, very obvious. In respect to the supposed curative effects, it cannot be doubted that ergot has had a distinct influence over the course of the disease. If the mortality by this method be compared with that which occurs in the course of other plans of treatment, the superiority of the ergot plan cannot be disputed. Such is the conclusion of Dr. Lardier. American experience is wholly new to this method. We trust some of our numerous readers will furnish us with new facts, and carefully recorded experience, demonstrating the real position of ergot as a remedy in the typhoid fever of this continent.

RHEUMATISM IN A CHILD.

In the very interesting case of acute rheumatism in a child of two and a half years, reported in another column, several important questions arise. As Dr. Smith very acutely says, the question of cerebro-spinal meningitis was considered in making up the diagnosis. The joint changes which ensue in cases of meningitis have been described by Dr. Charcot and others. The late Prof. J. K. Mitchell advocated the neurotic origin of rheumatism, and his son, Dr. Weir Mitchell, has published many observations proving the dependence of joint changes on spinal and nerve lesions. It is now, indeed, established that changes in the joints which cannot be distinguished from those of acute rheumatism, occur in cases of disease and in lesions of the spinal cord, the membranes, and the nerve trunks. This admitted, the case of Dr. Smith may be regarded from this point of view. The joint inflammation, the hyperpyrexia, the opisthotonos, and the muscular spasms (choreic), the whole concluding with coma, may be regarded as due to a common factor—meningitis. Whether one or the other view be taken, the case admirably illustrates the remarkable correspondence between acute rheumatism and certain spinal affections, and goes far to prove their community of origin. This admitted, acute rheumatism becomes not merely an inflammation of the fibrous tissues, but a neurotic affection.

THE PROPOSED ANATOMY ACT.

THE Philadelphia anatomists have prepared a new Anatomy Act very much such as we proposed editorially some time since. It was read in the State Senate for the first time on Saturday last. *We beg our Pennsylvania readers immediately to write to their Senators and Representatives*, and to impress upon them the urgent need for such an Act, the justice of its provisions, and the wisdom of its restrictions. It has still to pass two readings in the Senate and then go to the House.

It creates a Board of Distribution, consisting of the Professors and Demonstrators of Anatomy and Surgery in the incorporated Medical and Dental Colleges of the State, with one representative from each private school of twenty-five pupils or more. All persons having charge of the unclaimed dead to be buried at public expense, are to deliver them to this Board, who direct their distribution equitably, and bear all expenses of such distribution. A bond of $1,000 is required of all persons receiving them, that they shall be used for the promotion of medical science within the State, and a penalty is affixed to their exportation beyond the State, or to traffic in dead bodies, and to disobedience of the provisions of the law. Colleges and schools are to be first supplied, of course, but any physician or surgeon can obtain a body by filing a bond and applying to the Board.

The Act applies to the whole State, so that any physician or surgeon whose anatomical knowledge is rusty, may refresh and renew it at his home as occasion may require. That such renewed knowledge is needful, as the petition accompanying the bill well states, is evident from the fact that the want of it renders medical men liable to suits for malpractice, and such suits are on the calendar of well nigh every court in the State. The injustice of the restriction of the present law to the unclaimed dead from Philadelphia County alone (for that of Allegheny County is practically unavailable), is startlingly shown by the fact that in the last ten years at the Jefferson and the University, to say nothing of the other schools, there were 2,686 students from Pennsylvania, of whom 1,172 were from Philadelphia and *1,514 from other parts of the State*.

Moreover, to give the unclaimed dead of the whole State for dissection, will prevent the desecration of graveyards, and will relieve the counties from the expense of their burial, while aiding the community by the increase of knowledge, and by preventing students from going to other States.

THE ANALYSIS AND SYNTHESIS OF ANIMAL MOTION.

No one who has heard Mr. Muybridge, of San Francisco, lecture, and seen his remarkable photographs, can fail to be intensely interested in the revelation of the actual postures of the horse, hound, ox, and other animals, and in the revolution in his ideas of the proper methods of representing them. We had recently the pleasure of attending his lectures to the students of the Academy of the Fine Arts in this city. By a number of successive views at brief intervals by exposures of each photographic plate for not over the one five-thousandth part of a second, he has been able to analyze the various gaits of animals such as the walk, trot, canter, and gallop, and the various poses of man in walking, running, leaping, wrestling, and various acrobatic feats, and then by means of a modified zoëtrope and magic lantern has again reproduced the gaits by a synthesis of the successive plates. The rude blow he has struck at all the artistic representations of motion is at first a perfect surprise. The postures seem extraordinary, often impossible in view of our conventional notions, and not seldom even ridiculous. But the greater our familiarity with them and the longer we study them the truer do they seem.

As a contribution to the physiology of motion, they are most important; among artists they have made a deep impression, and have gained the approval of no less distinguished painters than Meissonier and Sir Frederick Leighton.

NEW CITY CHARTER FOR SAN FRANCISCO.

WE have just received a copy of the new city charter for San Francisco, proposed by the Board of fifteen Freeholders. It is an octavo pamphlet of 204 pages.

In the department affecting medical matters we observe that the coroner is not obliged to be a physician and that he serves for only two years—both very serious errors according to our judgment.

The Board of Health, on the contrary, is well organized, consisting of the Mayor and City Attorney and four citizens, of whom three must be physicians. The Health Officer, who is an appointee of the Board of Health, as is proper, must be a physician, and he is obliged once a quarter to visit each public institution under the control of the Board and to make a sanitary inspection of each public school once a year. Not only physicians, but also householders, must report cases of contagious disease. The Health Officer reports every such case to the Superintendent of the Public Schools, and this latter officer excludes from the public schools all the children in such families until their re-admission is authorized by the Health Officer. This is an excellent practical regulation.

We observe also that the assistant city physician makes all autopsies for the coroner without extra fees, and that the two surgeons to the City Receiving

Hospital are elected by the Board of Health from among the persons nominated by the faculties of the regular medical colleges.

We notice with satisfaction that Dr. W. F. McNutt is one of the Board of Freeholders who have drawn up this excellent charter.

Laborde has lately studied, by the experimental method, the actions of quinine and cinchonine. Although they are used as if possessing the same powers, important differences are discovered between them. Hence, the adulteration of quinine with cinchonine, now so much practised in France, is especially reprehensible. Cinchonine produces convulsions of an epileptiform character, which M. Laborde entitles *cinchonic epilepsy*. Quinine in much larger quantity has no convulsant action, but induces stupor, deafness, general muscular resolution, loss of the reflexes, and profound insensibility. The sophistication of quinine by cinchonine seems to be the explanation of peculiar phenomena occurring in some cases of fever, treated by quinine in antipyretic doses.

REVIEWS.

The Principles and Practice of Surgery. By John Ashhurst, Jr., M.D. Professor of Clinical Surgery in the University of Pennsylvania, etc. Third edition, enlarged and thoroughly revised. 8vo. pp. 1064. Philadelphia: H. C. Lea's Son & Co., 1882.

The appearance of the third edition of any work must always be gratifying to an author, as it is the strongest evidence of public appreciation of his work. A few additions have been made to the present edition, and tables and other statistics have been brought down to date, otherwise it differs but little from the last.

One of the most important points we notice is in the first paragraph of the "Addenda," in which the author records his continued disbelief in the special advantages of Listerism. We confess to some surprise in reading that the results recorded in Mr. Cheynes' *Antiseptic Surgery* are no better than "those which are habitually obtained in this country, at least by careful surgeons who do not adopt the antiseptic system."

The size of the volume prohibits any exhaustive treatment of each topic, but as a text-book, it is clear, succinct, conservative, and fair. As such we commend it unmeasurably.

Diseases of the Rectum and Anus. By Charles B. Kelsey, M.D., Surgeon to St. Paul's Infirmary for Diseases of the Rectum, etc. 8vo. pp. xii. 299. New York: William Wood & Co., 1882.

It is an improvement on the old plan of reprinting works of foreign authors, many of them out of date, for the publishers of "Wood's Library of Standard Medical Authors" to furnish their subscribers with the writings of Americans, and fresh ones at that. True, by no means in every case where they have followed the latter plan, has the production justified the use of the term "standard" in connection with the author selected. Nevertheless, it has been better for the reader, in the main, and in many cases no doubt far more satisfactory to the foreign author who has escaped adoption into this cis-atlantic family and all which it implies.

The book before us is one of the best of this series. It is the work of an industrious and studious specialist, who has added to experience a reading that has apparently been very extensive. The result is a really good book, a book which we think better to have and to consult than any other one book on this subject with which we are familiar, because the author has drawn upon all the good books we know of, and some we had never heard of before, for material to be added to that which his own observation could contribute.

It might seem as if nearly three hundred pages were a great many to devote to the consideration of diseases of the rectum and anus, and yet as we go over Dr. Kelsey's book we do not find them too many, if we except some filled with reports of cases. And, while other authors better known have been able to say what they wanted in less space, we think this one justified in taking more, in order that he may introduce and compare their views and express his opinion upon them. He has thus furnished a sort of *multum in parvo*, an opportunity to be in consultation at one time with a number of the ablest men who have considered this subject particularly, which will prove of real value to the student and practitioner.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 15, 1883.

The President, Fordyce Barker, M.D., LL.D., in the Chair.

After the reading and approval of the minutes of the preceding meeting, the report of the delegates to the New York State Society, signed by Drs. J. L. Adams, W. R. Birdsall, and Arthur M. Jacobus, was read, and upon motion, received and placed on file.

The scientific work of the evening consisted in a paper by Dr. W. H. Draper, entitled

DIET IN THE GOUTY DYSCRASIA.

The relations of food to normal nutrition, to the evolution of vital energy, and to the etiology and treatment of disease, he said, constitute some of the most interesting and important problems presented for the consideration of the practical physician. And it is one of the encouraging signs of the progress of scientific medicine that these problems are daily attracting and receiving wider and closer attention. The day has happily passed by when the selection of food is left to the instincts and intelligence of the patient. The physician is nowadays expected to prescribe the diet as well as the drugs, and the old adage that there is "death in the pot" is leading the laity to seek counsel of the doctor as to what they shall eat and drink, in order to antagonize the consequences of disease and to escape the perils that lurk in the indulgence of the table. It is only necessary to refer to the part which judicious feeding now plays in combating the evils of malnutrition arising either from inherited or acquired disease, to the daily increasing faith in the application of hygienic laws to therapeutics and the diminished confidence in a complicated pharmacy to illustrate the change that has taken place in the medical mind regarding the importance of diet in its manifold relations to health and disease.

The proper dietetic management of gout is a topic of great practical interest, because of the frequency

with which manifestations of the gouty dyscrasia are met with, and because, originating, as it does largely from errors in diet the correction of these errors constitutes an important part in the treatment of the affection.

Gout, as a disease, in the traditional acceptation of the term, is a specific arthritis characterized by the deposit of the salts of uric acid in the affected joints.

Gout, as a diathesis, is a blood crasis, in which there is an accumulation in the blood serum of the uric acid salts, due either to increased formation or defective excretion of these products of proteid metamorphosis. The manifold irritations of the different tissues and the accompanying subjective and objective symptoms are termed gouty.

Since the discovery, by Garrod, of the salts of uric acid in the blood serum of gouty patients, the humoral pathology of gout has certainly had more adherents than any of the many other theories. This pathology, based primarily on the chemical theory of digestion and food transformation, proceeds upon the view that every atom of albuminous or carbonaceous food ingested, whether destined for tissue construction, or the direct conversion of potential into active energy, is finally eliminated for the most part, as urea, carbonic acid, and water. This transformation, of course, is supposed to be effected by a process of oxidation, but neither the exact process nor the share of the various organs and tissues in its accomplishment are certainly known. Recent investigations point to the liver as chiefly concerned, not only in the metamorphosis of the carbohydrates, but also in the formation of urea, so that the arrest in the conversion of starches and sugars, resulting in glycosuria, and the check in the metabolism of the proteids, resulting in lithæmia, may both be due to hepatic derangement. The not infrequent association of glycosuria and lithæmia in the same patient, and the frequent alternation of gout and saccharine diabetes in gouty families are significant facts in support of the common origin of these diseases.

The suboxidation theory of gout and diabetes, ably presented by Bence Jones, has much to commend it from the valuable suggestions it affords in the clinical management of these maladies. Nevertheless, while defective oxidation seems to be an essential factor in the production of gout and diabetes, it is impossible to reduce this factor to the simplicity of a chemical equation. All that can be said at present is that the metabolism of food is in its nature a chemical analysis, modified and regulated by vital force, and resulting in the formation of tissue, and the conversion of potential into active energy. Imperfect blood elaboration must depend upon much beside a disturbance of the proper relation between the amount of food ingested and oxygen inhaled, though this must unquestionably be an important factor in its causation. Heredity, and the mysterious influence of the nervous system complicate the problem; so that while it may be maintained that gout is a disease in which suboxidation occurs, it is not possible to tell whether the suboxidation is the essence of the disease, or only one of its phenomena. Indeed, a much more complex process than the simple accumulation of uric acid in the blood is probable. Uric acid, like urea, is one of the normal results of the metamorphosis of albuminous foods and tissues. In birds and most reptiles it is the final issue of this metamorphosis. It has been supposed, as one atom of uric acid can be split by oxidation into two atoms of urea and one of mesoxalic acid, that uric acid was the antepenult of urea. This, however, is by no means proven. In birds, who consume by their rapid breathing an enormous proportion of oxygen, as well as in the slow-breathing reptilia, the nitrogenous excrement takes the form of urates. In view of such divergent conditions, variations in proteid metabolism cannot be explained by varying degrees of oxidation.

When we have said that urea is destined for a fluid, and the urates for a solid excretion, we have exhausted our powers of explanation. Moreover, there are clinical as well as physiological objections to the uric acid pathology of gout. Uric acid salts accumulate in the blood in fevers, in disorders of digestion, and in anæmia; but do not cause either the symptoms or lesions of gout. Todd held that gout might occur without an excess of uric acid in the blood, and it is certain that this is true of the atonic and irregular forms. Again, the diminished power of the gouty to digest farinaceous and saccharine foods, tends to stamp uric acid as an epiphenomenon, rather than the sole exciting cause. The primary indigestion is promptly relieved by restricting the diet largely to albuminous foods. This restriction, furthermore, is one of the surest prophylactics against the recurrence of gouty lesions. It is well known that the fermented liquors are among the most frequent exciting causes of acute gout, and cases are not uncommon in which sweet foods and fruits will provoke well-recognized lesions of the disease. This anomaly in the uric acid theory may possibly be explained by the suggestion of Garrod, that the deposition of the urates is due to their insolubility, and as this insolubility is increased by diminished alkalinity of the serum, that the evolution of acids in the digestion of the carbo-hydrates so lessens the normal alkalinity of the blood, that the uric acid salts are precipitated. But this explanation does not do away with the fact that carbonaceous foods may be as much, perhaps more concerned in the causation of gout, than the albuminous foods. The chemical pathology of gout, in view of the conflicting evidence, seems to be still involved in considerable obscurity.

Recent advances in neuropathology have led many to advocate the theory that gout is a tropho-neurosis. The frequency of purely nervous symptoms in gouty persons is daily observed by those who have much opportunity to study the disease. Any of the functions of the entire nervous system may be affected. Psychical disturbances, as hypochondriases and hysteria; derangements of sensation, as neuralgia and dysæsthesia of every variety; and spasm of both voluntary and involuntary muscles, as cramps, grinding of the teeth, asthma and vesical tenesmus, are met with. Often attacks of gout are determined by purely nervous influences, such as nervous exhaustion, whether caused by overwork or mental anxiety, or the more explosive discharges of nerve force in rage and great emotional excitement. The influence of certain diseases of the nervous centres, such as cerebro-spinal meningitis. Pott's disease and tabes dorsalis, in occasioning gouty manifestations, tend to favor the theory of the nervous origin of the affection. Still, such facts do not disprove the humoral pathology. Healthy nervous action must depend primarily on normal nutrition, and this, in turn, on healthy blood elaboration. It may be that gouty lesions are determined as reflex phenomena through the medium of the trophic centres, if such centres there be, rather than by the direct irritation of the affected tissues by the gouty blood, and it is not unreasonable to suppose that nervous exhaustion may produce in these centres greater reflex excitability.

This brief pathological *résumé* sets forth the theories upon which treatment has been based. Clinical experience, however, does not fully bear out either the chemical or neurotic theory. Whether gout is a tropho-neurosis determining the chemical changes, or whether the chemical changes are primary, and determine the lesions through central or peripheral nerve irritation, are questions impossible now to answer. It is fair,

however, to say that the treatment based on the neurotic theory is better adapted to the acute articular lesions, while that based on the humoral theory is better adapted to the management of the constitutional vice.

But the suboxidation, whether primary or secondary, it is shown by clinical experience, occurs not only in the nitrogenous, but also in the carbonaceous foods. The treatment of the gouty dyscrasia should therefore insure, primarily, the complete combustion of both these classes of food. The means of accomplishing this result are partly dietetic, partly hygienic, and partly medicinal. The dietetic means consist in the choice of such foods as the gouty patient most easily converts; the hygienic include the maintenance of an abundant supply of oxygen for the thorough conversion of the potential force of the food into the various forms of vital energy, and the medicinal means the use of such drugs as facilitate oxidation, and the elimination of waste products. Leaving the hygienic and medicinal means for the present, the speaker took up the dietetic means.

The dietetic treatment of gout invites a consideration of the quantity and the quality of food best adapted to maintain a healthy nutrition and a proper equilibrium between the potential energy contained in the food and the active energy evolved in its transformation in the body. An approximate estimate only, as to quantity, is possible. The well-fed classes probably always consume more than is perfectly digested. Experiments of various sorts have been made, but none show, except approximately, the amount really required. Moreover, different individuals require widely different amounts; some persons maintain a good degree of health and capacity for exertion with one-half the quantity of food that others require. Excess of food is unquestionably one of the most important factors in the causation of the evils arising from suboxidation. This excess may be positive or relative; positive when it is more than can, by any possibility, be oxidized, relative when it is more than is required by the habits and occupation of the individual. The proper quantity of food is necessarily variable, and must be proportioned to the age of the individual and to the amount and nature of the work to be performed.

Authorities have almost uniformly held that gouty patients should use albuminous food sparingly, and that their diet should consist mainly of non-nitrogenous articles of diet, giving preference to the farinas. This teaching is based on the theory that uric acid is the offending substance, and this being one of the products of imperfect metabolism of nitrogenous foods, such foods should be largely withheld. A personal experience of fifteen years led the speaker to believe that while such may be the logical deduction of the uric acid theory of gout, clinical facts do not bear it out. The non-nitrogenous rather than the nitrogenous foods should be excluded.

Gouty persons, it is well known, have but limited capacity for the digestion of carbo-hydrates, the sugars and the starches. They occasion, in whatever form used, more dyspeptic trouble than albuminous foods, causing the acid and flatulent indigestion with its accompanying reflex disturbances that generally precede the explosion of gouty attacks. What acute observer has failed to notice that the dyspeptic disorders of the children of gouty parents are especially provoked by saccharine and amylaceous foods?

It is impossible to satisfactorily explain why the lithæmic condition should be brought on by the indigestion of carbonaceous food. If, as modern physiology tends to show, urea as well as glycogen is formed in the liver, it may be that over-taxing the functional activity of this organ manifests itself more readily in the incomplete conversion of the nitrogenized than in that of the non-nitrogenized foods. Whatever may be the explanation, however, the clinical fact remains, that the conversion of albuminous food is more complete with a minimum of carbo-hydrates than it is with an excess of them.

The diet in gouty subjects, therefore, is similar to that called for in glycosuria. The exclusion of the carbo-hydrates need not be so complete, however. The degree of suboxidation which checks the transformation of the starches and sugars in diabetes mellitus is greater than that which results in the production of the various acids which are formed in the conversion of starch and sugar into carbonic acid and water. The classes of food in the order of their indigestibility in the gouty diathesis are, first, the sugars; second, the starches; third, the fats. Above all, fermented alcoholic substances are productive of the greatest disturbance. Experience has taught this to the laity, as well as to the profession. There is a striking difference in the effects of the distilled and fermented liquors. Gout is certainly more prevalent where fermented rather than where distilled beverages are used, *e. g.*, it is much more common in England than in Scotland or Ireland. In Russia and Poland, where spirits are more exclusively used, it is said to be rare. Moreover, fermented liquors differ in their tendency to induce gout. The heavier wines, sherry, Madeira, and port, are more mischievous than the lighter wines of France and Germany. Nevertheless, these wines, especially the richer clarets, Burgundies and Rhine wines, frequently give rise to acute gout, and the gouty habit. Malt liquors are unquestionably pernicious as gout producers, especially the stronger English and Scotch ales, and, to a less degree, the lighter English, American, and German beers. Cider is also injurious, as, for example, is shown by its action in certain districts of England. Although acute articular gout is said not to be common in New England, where cider is much used, it undoubtedly develops the irregular forms of gout. The large amount of sugar in cider favors the production of the acid dyspepsia which is a common antecedent in the formation of the gouty dyscrasia. Malt liquors also contain more or less unfermented sugar. These, even the lightest varieties, should be absolutely prohibited. Though beer and ale drinkers are apt to suffer more often and from a greater variety of gouty manifestations than wine drinkers, it may safely be said that the less wine ingested the better. Wines are detrimental in proportion to the quantity of unfermented sugar they contain. . Very few contain absolutely none. Some of the light Hocks, Moselles, and Bordeaux wines are said to contain none, and the driest of the dry champagnes certainly contain very little. They, therefore, are the best varieties to allow the victim of gout. But these are not always to be trusted. Most imported clarets contain sugar, and are fortified with alcohol to check fermentation, and they are very often the source of gout in some of its forms. Sherry, Madeira, and port contain the largest proportion of unfermented sugar, and are, therefore, *par excellence*, gouty wines. The safest alcoholic beverage for the sufferer from gout, if he uses any, is a very dilute spirit, and this should always be taken with food—never upon an empty stomach. Sufferers from the regular forms of gout usually learn by their own experience that they should use spirits moderately, if at all, and that they should entirely abstain from fermented liquors; but sufferers from the irregular forms, such as the cutaneous, and mucous, and the innumerable gouty neuroses, not recognizing their ills as of gouty origin, frequently indulge in what they deem the moderate use of beer and wine.

Next to the fermented liquors, the use of saccharine foods should be restricted, as common, no less than

professional experience dictates. This prohibition sometimes involves abstinence from the sweet and subacid fruits, which are for the most part highly flavored mixtures of starch, sugar, and acid. Paroxysms of articular gout, and more frequently the cutaneous and mucous irritation from which gouty persons suffer, follow indulgence in strawberries, watermelons, apples, and grapes.

The third class of interdicted foods are the starches. These form necessarily so large an element in ordinary diet that their limitation in the regimen of the gouty applies only to their excessive use. This excessive use, however, is often met with, probably because of the common prejudice against animal foods as a cause of gout. The feeble capacity for the digestion of farinaceous foods occurs most frequently in those inclined to obesity, and in those whose occupations are sedentary, or whose lives are largely spent indoors, and in the indulgence of indolence and ease. It is less common in those whom necessity or pleasure lead to much open-air exercise.

The fats are easily digested, according to the speaker's experience, by most gouty dyspeptics—a fortunate fact, since in the anæmic state, which frequently accompanies chronic gout, the fatty foods are of inestimable value. Milk, in persistent and rebellious lithæmia, is one of the best articles of food, and a purely milk diet constitutes a precious resource in cases in which the disease cannot be otherwise controlled.

The succulent vegetables, as tomatoes, cauliflowers, cabbages, asparagus, artichokes, cucumbers, and indeed almost all the vegetables, except such as are purely starchy like potatoes, or starchy and saccharine like squash and beets, may be used with safety.

In conclusion, the principles upon which the diet of gouty persons should be regulated are mainly, in a modified form, those upon which the diet in glycosuria is based. As regards quantity, attention must be paid to the age, habits, environment, and occupation of the individual; as regards quality, to the habits and occupation, and especially to the fact that the ability of gouty persons to digest sugars and starches is always more or less enfeebled. A bill of fare for the gouty dyspeptic is not so uninviting as it might at first sight appear. If he is an out-door worker and accustomed to much muscular exercise, he may need to forego alone the fermented preparations of alcohol, and be able to give free rein to his appetite for all the viands which the animal and vegetable kingdom supply. If he is an indoor worker and engaged in intellectual or the more delicate mechanical occupations, the victim of a limited supply of oxygen and a feeble circulation, he had better not try to live on potatoes and puddings, or to quench his thirst with beer and wine.

DR. HODDEN remarked, in opening the discussion, that he endorsed the views expressed in the paper, especially as regards treatment. An experience of four or five years convinced him that the results of the diet advocated were as had been stated. The restitution of the carbo-hydrates and the free use of nitrogenous foods, had counteracted the evil effects of the gouty dyscrasia in the subacute and chronic cases, which had chiefly come under his management. The urates of sodium were thereby diminished in the blood and urine. The return of the gouty symptoms when the diet was not properly managed showed that there was something more than theory in the views set forth regarding proper feeding. He had given salicylate of sodium several times a day for a considerable time uninterruptedly, but it had had no other effect than to counteract the acidity of the stomach. Comparative study of birds and of the carnivorous and herbivorous animals, was not only interesting but instructive. Gouty deposits are found in the feet of parrots and pigeons. Carnivorous birds kept in confinement show no such deposits. In herbivorous animals, for instance the horse, it is not uncommon to find deposits in the form of the urates of sodium. The disease commonly known as ringbone is due to such deposits. No deposits of the urates are found in cats or dogs. These facts were suggestive and supported the line of treatment recommended in the paper, by the pursuance of which much better results were obtainable than had been met with heretofore by other methods.

DR. M. PUTNAM-JACOBI thought that a statement to the effect that there was a condition of suboxidation, did not correlate the facts in this disease; the facts of heredity, the nervous phenomena, etc., which existed. As to the value of a purely meat diet in diminishing uric acid, she could call to mind many cases which proved it. Before restricting patients to a diet consisting of meat and gluten bread, she determined the existence of an excess of uric acid and urea in the urine by a quantitative chemical analysis. An enormously fat woman under treatment for obesity, being placed upon this strict diet, became so prostrated in the course of ten days that it was thought impossible to continue it. However, by the administration of nux vomica and nitro-muriatic acid, she did continue the diet, with the result of a reduction in weight of forty pounds at the end of a year, together with an increase in strength.

DR. JANEWAY called attention to the fact that where a milk diet is used we are giving a good deal of sugar, and that, too, in a form that will admit of fermentation. If we accepted the neural pathology, we ought to find more nervous patients suffering with the disease. He had examined many joints of nervous patients without finding any trace of it. He called attention to the fact that cases of gout may be determined by an injury or by nervous prostration. On the whole, he was inclined to look with greater favor upon the humoral than upon the neural pathology of the disease.

The PRESIDENT, being called upon for an expression of opinion, said that the views advanced in the paper were so completely at variance with his own that he felt the need of more time for study and reflection before formulating his ideas. He then cited a number of cases, each of which presented contradictory symptoms to all the others, and were relieved or made worse by exactly opposite kinds of remedies. He thought that no one plan of treatment would answer for all cases. It was necessary to study the peculiarities of each case, and be governed accordingly when prescribing.

DR. FLINT thought that the subject under discussion could only be settled by clinical experience. He would feel extremely doubtful in regard to accepting any treatment as final which was based upon pathological views derived from neurology or chemistry. He thought there was another point to which sufficient importance had not perhaps been attached, and that was the element of dyscrasia. There was probably no disease in which dyscrasia played so strong a part as in gout. The hereditary influences should always be sought for. The disease develops at a certain period of life, but the precise reason for this we cannot say.

DR. DRAPER, in closing the discussion, said he had found no difficulty, or at least very rarely, in getting patients to adhere to the diet prescribed. He had not had occasion to make the diet so strict as suggested by Dr. Jacobi. He thought patients who were confined to a diet of that sort would be very apt to become rebellious after a time and require some indulgencies. He had never found any difficulty in adding to this diet green, succulent vegetables, and they certainly contribute greatly to the comfort of the patient. Dr. Janeway's remark in regard to milk was true, and

this was antagonistic to the theory that gouty patients do not digest sugars. But in giving milk he thought it was necessary to give more or less alkali. When soda was given with milk the latter was well borne, and gave no disturbance. This he supposed was due to the fact that any tendency to acidity was promptly corrected by the soda. The speaker entirely concurred with Dr. Flint in his injunction that this question is to be settled clinically, and in giving the diet he had stated that its good effects could not be explained by pathology or justified by it. He did not think any one could explain why an animal diet agreed with gouty persons, but his experience has shown that it did. He supposed all who had seen much of gout and studied it had met with many such contradictory facts as had been cited by the President. He could see no explanation for many of them, except on the ground of a neural pathology.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, February 1, 1883.

THE PRESIDENT, R. A. CLEEMANN, M.D., IN THE CHAIR.

DR. B. F. BAER read an

ANALYSIS OF TWENTY-SEVEN OPERATIONS FOR THE RESTORATION OF THE LACERATED CERVIX UTERI, WITH SPECIAL REFERENCE TO THE EFFECT ON STERILITY AND LABOR.

In the discussion which followed the reading of Dr. Playfair's paper on "Trachelorrhaphy, or Emmet's Operation," before the Obstetrical Society of London, on March 1, 1882, Dr. Herman, in the course of his remarks, said that "The American literature on the subject consisted mostly of general statements. Few writers had published cases, and the cases were mostly complicated ones." There is some force in these words. But, to avoid a monotonous repetition, it is desirable only to publish such as are strongly illustrative of the class to which they belong, or such as bear directly upon any point which may be under discussion.

In the *American Journal of Obstetrics*, for January, 1883, Dr. P. J. Murphy, of Washington, D. C., makes some "Observations on the Effects of Trachelorrhaphy on Fertility and Parturition," and comes to the conclusion "That repair of lacerations of the cervix uteri is usually followed by sterility." Now, there is no doubt of the truth of this statement, so far as it goes, but I think he ought rather to have said that, in those cases in which sterility followed the operation, that condition also preceded the repair of the cervix in the majority of instances, either as a result of the laceration itself, or of its effects on the uterus and its appendages; and that the operation was not the cause of the sterility, but that it simply failed to cure it.

The only way to arrive at anything like a correct conclusion on this subject, is to take a number of cases (it need not be large), and analyze them, and this I purpose doing with mine.

Of the twenty-seven cases in which I have made the operation, six were either widows, or had reached or passed the menopause, and must therefore be excluded from the analysis. This leaves twenty-one cases to be reported upon in this inquiry. Of these twenty-one cases, thirteen had been sterile from five to sixteen years previous to the operation, and I think, for reasons which I will give farther on, that they ought also to be classed as beyond the probability of becoming pregnant. In the remaining eight cases, pregnancy had occurred within five years, but had resulted in abortion in five. In twelve of the twenty-one cases, from one to five abortions had occurred in each subsequently to the occurrence of the laceration. This gives abundant proof of the ill-effects of the lesion and its results, subinvolution, chronic hypertrophy, cellulitis, oöphoritis, etc., on fertility.

Is the assertion that sterility usually follows, as a result of the operation, correct? I do not think so; provided, of course, that the operation was properly made, that the os was not made too small, and that immediate union followed the coaptation of the parts, so that there was left the minimum amount of cicatricial tissue to interfere with the normal resiliency of the cervix.

The oftener abortion occurs, as a rule, the greater and more persistent will be the histological changes in the uterus and its appendages, which finally result in sterility.

The majority of cases in which the operation has been made have been of long standing, because the operation is new, and there were many old cases of so-called "ulceration" with chronic hypertrophy, waiting ready to be experimented upon with this as they had been before with many other old and new remedies.

Is this last new remedy followed by any greater success than the old in the reduction of the size of a large uterine body, which has become hard and fibrous from connective-tissue hyperplasia? I think not; and hence its failure to cure sterility of long standing, from this cause. But, for the cure of certain cases of hypertrophy of the cervix, inflammation, ectropion and abrasion of the mucous membrane, with their local and remote symptoms, and possibly, even probably, preventing epithelioma, and in the more recent cases for the cure of subinvolution, abortion, and sterility, the operation is an immense stride in advance of the old way of destroying the tissues of the cervix by amputation, or by the application of the hot iron or the potential cauteries. It is an advance, because it restores the cervix instead of destroying it.

The following case proves, I think, that abortion may result from laceration of the cervix, although none of the usual inflammatory consequences of the lesion are present.

Case I.—Mrs. M. L., æt. 30, consulted me in January, 1881. She was delivered of her first child two years previously. The labor was rapid. The child was fully developed and vigorous. There was nothing unusual in the puerperal period, and she seemed to be well. Ten months after the birth of the first child she became again pregnant. Between the second and third months of gestation the product of conception was expelled with little pain, but it was followed by severe hemorrhage. Within three months she was again pregnant, and aborted at about the same time and manner as previously. This was followed within six months afterwards by a third pregnancy, and abortion under similar circumstances. The last occurred about two months before she consulted me. She had absolutely no symptoms of uterine disease, such as leucorrhœa, menorrhagia, and the pain which always results from congestion and hypertrophy of the uterus; and expressed herself as feeling as well as ever she had in her life. There was no evidence, whatever, of syphilitic infection, either in the patient herself or in her husband. They are both robust and well developed.

Examination.—The perineum and vagina were normal. The uterus was in normal position; it was neither congested nor enlarged; but the cervix was lacerated on the left side to a point beyond the vaginal attachment, apparently approaching and involving the fibres of the internal os. On the right side there was a mere fissure only. There was no hypertrophy, eversion, or abrasion of the mucous membrane. The sound passed to a depth of two and a half inches. I expressed the opinion that the lacerated cervix and the abortions

stood in the relation of cause and effect; and I advised an operation for the restoration of the torn cervix.

On March 10, 1881, I denuded the surfaces, being careful to remove very little tissue, and to freshen the edges as far up towards the internal os as possible. I then placed six carbolized catgut sutures, and clamped them with shot. I used the gut suture here in preference to the silver wire, because, as the cervix was not large, and the tear principally unilateral, there would not be much tension, and for the additional reason that I especially did not want any cutting of the tissues by the sutures, which is more apt to occur when wire is used. Another advantage of gut suture is that the line of union need not be disturbed by the removal of the stitches. On the seventh day after the operation I inspected the cervix through Sim's speculum, and found the sutures all *in situ*, though they were partially absorbed. Union was perfect. Two days afterwards the shot were lying loose in the vagina. There had not been the slightest discharge from the united surfaces since the operation.

On June 3, 1881, the patient reported that she had not menstruated for seven weeks, and there was every indication that she was pregnant. A week later I was requested to visit her. I was much chagrined to find when I arrived that she had aborted. This was very discouraging, but I found some comfort in the character of this abortion. More pain attended the expulsion, and less hemorrhage followed it than on the previous occasions. This I ascribed to the restoration of the symmetry of the cervix, and its better retentive power.

On October 9, 1881, she reported that she was about two months pregnant, and feeling well; and on May 7, 1882, she was delivered at full term of a fully developed healthy boy, after a perfectly normal labor of six hours' duration. Examination two months afterwards revealed not the slightest laceration of the cervix. The mother and child are both well.

Case II.—Mrs. M. R., æt. 21 years, consulted me in May, 1878. She had been delivered eight months before of her first child; the labor being tedious, was terminated with the aid of the forceps. The puerperal period was also tedious, and she had ever since been troubled with pain in the hypogastric and lumbar regions, together with a profuse leucorrhœa. Coition was painful, and followed by slight hemorrhage. She was anæmic, and had lost flesh.

Physical Exploration.—The perineum was slightly lacerated and the vagina relaxed. The cervix uteri was pressing low down on the pelvic floor, and lacerated bilaterally, but to a greater degree on the left than on the right side. The tissues were soft from engorgement, and the mucous lining of the cervical canal greatly hypertrophied, everted, and abraded of its epithelial covering, so that it bled on the slightest touch. The uterine body was likewise congested and tender, The sound gave a measurement of minus three inches.

I treated this patient locally and constitutionally for almost a year, with marked general improvement, and although the local condition would improve, the benefit was only temporary. On April 30, 1879, I made the operation for lacerated cervix, placing seven silver sutures. Perfect union resulted.

Three months after the operation she became pregnant, and was delivered spontaneously at full term, The labor was so easy that delivery occurred before the arrival of the physician. Two months after the labor she called at my office, at my request, and I found the cervix healthy, although there was a very slight fissure on the left side. She stated that she had been well since the operation.

Case III.—Mrs. A. B., æt. 34 years, was sent to me in July, 1880. She had had eight children, the youngest of which was six months of age. She stated that she always menstruated during lactation, and became pregnant when her children were about eight months old. Since the birth of the last child, she had had metrorrhagia every three weeks, lasting one week, and a profuse leucorrhœa for years. She complained of pain in the lumbar region, with a heavy dragging sensation in the pelvis and on the top of the head. She was emaciated, and so pale that she appeared bloodless. She had become hysterical.

Touch.—The perineum and vagina were very much relaxed. The cervix uteri was far back, and presented a nodular surface, the result of three deep rents in its tissue, one of them extending through the centre of the anterior lip, flush with the vaginal junction. There was marked ectropion of the mucous membrane, with abrasion. The body of the uterus was anteverted, and only slightly larger than normal.

I placed this patient upon the "rest treatment" of Dr. S. Weir Mitchell (modified somewhat to suit the circumstances), in addition to the necessary local treatment. Her improvement was very marked, and on October 10, 1880, three months after she first came under my care, I operated for the laceration, and secured immediate union.

Under the date of October 27, 1881, a year from the date of the operation, I find this note in my case-book: "Returns to-day at my request for examination. She has improved so much in appearance that I scarcely knew her, and she states that she has been well since a short time after the operation. The cervix is perfectly normal, and gives no evidence that an operation has been made."

I recently received from my friend, Dr. Wm. L. Taylor, the following note concerning this lady:

"DEAR DOCTOR: In answer to your inquiry regarding Mrs. B., I will state that she was confined six weeks ago. The labor was natural, and if it differed in any way from her former labors, it was more rapid. I examined the cervix to-day, and found the external os patulous, but no laceration."

Case IV.—Mrs. X., æt. 35, who had had seven children and two abortions, the last one nine months before, was sent to me in September, 1880. She complained of pain in the lumbar region, a heavy dragging pain in the pelvis, and very difficult and painful locomotion. These symptoms had been growing in severity for several years. She also had menorrhagia and leucorrhea. *Touch:* Cervix large, soft, and lacerated bilaterally flush with the vagina. Mucous membrane engorged, everted, and eroded. Uterus retroverted but mobile. The sound passed three and a half inches. On February 27, 1881, I closed the rent, placing seven sutures, union immediate. The result on the symptoms was all that could be desired. A letter received a few days ago, in anwer to one of inquiry from me, informed me that this lady is now pregnant.

Here are four cases, in which pregnancy followed the operation, out of the class of eight in which impregnation had occurred within five years previous to the restoration of the cervix. And that there will be more I feel sure, because a sufficient time has not yet elapsed since the operation was made, in some of my cases, to prove that sterility will continue.

That sterility does not result as a consequence of the operation, when the proper precautions are taken to secure immediate union and a normal-sized os, does not this analysis prove? That it will prevent a recurrence of abortion, and cure sterility of recent date, Cases I. and II. give undoubted evidence. That it will fail to cure sterility of long standing, for reasons given in this paper, I am convinced from my own experience. Time, however, may prove that a small percentage of this class will also be benefited in this direction.

I have selected the following case from the class of thirteen in which sterility had existed more than five years prior to the operation, as strongly typical of the point I wish to illustrate, viz., that the longer the time which has elapsed between the occurrence of the injury and its repair (pregnancy being absent during this time), the greater and more permanent will be the changes in and about the uterus, which almost necessarily result in a continuance of the sterility after the cervix has been restored.

Case V.—Mrs. M. R., æt. 39, consulted me in the fall of 1880. She had had six children, the last one thirteen years before. Her labors were all normal, so far as she knew, except the last. This was complicated by a malposition. The forceps were applied two hours before the delivery of the head, and great traction effort was necessary. The child was so injured by the forceps that it died on the third day after delivery. The patient was unable to be out of bed for nearly three months afterwards, and the bloody lochia continued during two months. She had suffered from menorrhagia ever since, and recently from metrorrhagia every two weeks, at times amounting to "almost a flooding." In the intervals between the hemorrhages, she had a constant and profuse mucous leucorrhœa. She complained of a deep-seated pain in the pelvis, "sawing" in character, with pain in the sacral and lumbar regions and across the shoulders. Coition could not be tolerated because of the pain it induced, and the hemorrhage which resulted.

Examination.—The perineum showed an old laceration of slight extent, and within an inch of the vaginal orifice the finger came upon a large mass of tissue which filled and distended the tube. It was hard and nodular around its border, but softer and rather friable in its centre; and it bled on the slightest touch. It gave me, at first, an impression of epithelioma, and I could readily detect that the cervix was bilaterally lacerated down to the vaginal attachment. The body of the uterus was hypertrophied, indurated, retroverted and slightly fixed from contraction of the broad ligaments. Through the speculum the cervix was seen to be lacerated, as the finger had indicated, and that the softer tissue, which occupied the space between the separated lips, was redundant mucous membrane, which seemed to have united from side to side, leaving a very small opening in the centre, corresponding to the external os. This tissue was dotted all over its surface with whitish spots—Nabothian cysts. The sound passed to a depth of minus four inches, and showed the uterine cavity to be rugous—vegetations of the endometrium. I now punctured the retention cysts, and found that the redundant tissue between the torn and separated lips was riddled with them. So much hemorrhage resulted from the scarification that, to check it, I was finally compelled to tampon the vagina. On the next day I removed the tampon, and found the mucous membrane much reduced and less congested.

I treated this lady during a number of months for the purpose of relieving symptoms, and preparing the parts for an operation on the cervix. The hypertrophy and congestion of the mucous membrane of the cervix and uterine cavity were considerably reduced, the metrorrhagia and leucorrhœa diminished. The uterus became more mobile, and tenderness subsided; but the parenchyma of the cervix and body of the uterus remained sclerotic and unreduced in size.

On February 10, 1881, I closed the rent after denuding the surfaces, and dissecting away a large amount of cicatricial tissue from the sides and angles. I placed eleven silver sutures. Considerable difficulty was experienced in passing the needles through the dense and tough cervix, and I broke and bent several before I succeeded in placing all the stitches. The surfaces did not unite as readily in this instance as is desirable, but union was finally established by granulation, resulting in the formation of a good cervix.

This patient has been entirely relieved of the leucorrhœa and pain of which she complained, but she still has an occasional menorrhagia, and the body of the uterus remains large and hard, the sound entering three and a half inches. As was to be expected under these circumstances, she has remained sterile, but certainly not as a result of the operation.

Dr. Murphy further says: "I fear I shall never arrive at that perfection where it will be given me to appreciate why a laceration of the cervix, by being repaired, will probably prevent cancer of the womb."

I do not wish to discuss this subject here, as I am preparing a special paper upon it, but I would like to say that, if we believe that cancer may develop in consequence of the changes in the circulation and nutrition, which necessarily follow when the cervix is torn, and it seems to me that one need not have arrived at perfection in the art of appreciation to believe that cancer might develop in a field such as was presented in Case IV. previous to the operation, then restoration of the organ ought to prevent cancer.

He also concludes, "That the character of the labor is unusually severe and protracted, and that, in a large percentage, laceration occurs a second time."

That this statement is too sweeping is abundantly proven by the cases I here record. I can believe, where pregnancy has happily followed the operation in a case of long standing, in which the cervix is sclerotic from connective-tissue hyperplasia, and cicatricial from non-occurrence of immediate union, that the first stage of labor might be tedious, and that relaceration might take place. But, suppose relaceration does occur in some cases, is that sufficient reason to deprive the patient of the benefits which usually accrue from the operation independent of pregnancy?

Not long ago I made the operation for the restoration of a lacerated perineum, which extended fully an inch and a half up the recto-vaginal septum, on the person of a lady fifty-one years of age. The laceration occurred twenty-six years before with a severe forceps labor. She had been debarred from the society of her friends, and made loathsome to her husband as well as to herself all these best years of her life. In answer to my inquiry why she had not sought relief long before, she replied that she had done so, but that she had been advised to wait until after the menopause for fear that, in the event of another parturition, the parts would relacerate! Comment on such argument as that is unnecessary.

The comfort which this lady has enjoyed since the rectum and perineum have been restored, causes her to feel far from kindly towards the gentlemen who advised such conservatism.

I have recently delivered two ladies on whom the operation for lacerated perineum was made about three years ago, one by Dr. Goodell, and the other by myself. Relaceration did not occur in either.

DR. GITHENS stated that on June 18, 1878, Dr. A. H. Smith had operated upon Mrs. M., for the restoration of a lacerated cervix; and on July 10th of the same year had performed perineorrhaphy, both operations proving successful. On June 19, 1879, a year and a day after the first operation, he delivered her of a boy at full term, the labor being uncomplicated and easy, and no tear of either cervix or perineum occurring.

DR. E. E. MONTGOMERY remarked that as regards the question of sterility resulting as a consequence of the restoration of a lacerated cervix, he had been operating since 1879, and five of the patients he had op-

erated upon have since become pregnant. The first patient upon whom he operated became pregnant lately, but aborted; as she had desired not to become pregnant, and was anxious that an abortion should occur, he believed that it had been artificially induced. Another patient, operated upon in 1880, had been delivered in January, 1883, without accident. A patient operated upon in 1879 is now four months advanced in pregnancy; before the operation she had aborted at three months; this accident was apparently consequent upon the existence of the laceration. Of these five cases, two were lacerations of long standing, and three were recent.

DR. CLEEMANN had operated upon one case of nine years' standing. During the first two years of that time she had two miscarriages, and then remained sterile for seven years. The operation was performed eleven months ago, and she is now two months advanced in pregnancy.

DR. A. H. SMITH had heard Dr. Baer's paper with pleasure. The general impression in this city is that sterility is a consequence of the injury, and a large proportion of the cases operated on by him have become pregnant after operation. The fear of the recurrence of the accident prevents pregnancy in many cases, as means are used to avoid that condition. Improved general health and local comfort are a result in a majority of the cases, even where pregnancy does not occur. He would like to hear Dr. Baer's experience about the existence of obstinate nausea in pregnancies after operation upon long-standing cases, accompanied with an enlarged and hardened condition of the cervix. It has been so with him. As regards the result of labor, there has been no tendency to relaceration in the same position. He used inhalations of chloroform and hot-water douches in such cases, and does not rupture the membranes early; he also prevents the patient from bearing down, and by these means secures a slow and safe labor. He is sorry to hear that Dr. Baer has no confidence in the power of the operation to reduce the size of a hyperplastic uterus. He has seen cases of the so-called sub-involuted uterus, after the complete failure of local means, such as iodine, silver nitrate, etc., reduced to one-third of its bulk by operating upon a laceration of the cervix. The rapidity with which the ultimate result of reduction in size is reached is in proportion to the time that has elapsed since the injury.

When the cervix is much hypertrophied, and ectropion exists, such a cervix as would formerly have been called cancerous and would have been amputated, the stitches should be left in a long time. If they are removed too soon there is a proneness to gaping, a sort of ectropion or sprouting. This will not happen if the sutures are allowed to remain thirty or forty days.

DR. WM. GOODELL regretted that he was too late to hear Dr. Baer's paper. With reference to the question of the influence of the operation on causing sterility, he thinks it does have such an influence. He has operated in one hundred and sixty-nine cases, and has only known of seven who have since become pregnant. There were probably more, as the cases have passed away from his knowledge and he has never heard of them again, as he does not practise obstetrics outside of the Preston Retreat. In two of the seven cases, a second operation was required, but it was slight. In one case not the slightest change occurred in the form of the os. As regards the effect of the operation in preventing cancer, he believes it fully, both from experience and from *à priori* reasoning. He has seen but two cases of epithelial cancer in women who have not borne children. In fact his experience has been that the greater number of children, the greater the liability to carcinomatous degeneration, and often the notch of a previous laceration is seen in the cancer. If carcinoma is, as we believe, a local disease at its beginning, what more probable cause could we have than such an irritating sore as a bad laceration of the cervix. In more than one case his principal reason for operating for the restoration of the cervix has been on account of a history of cancer in the family.

Concerning the effect of the operation upon hyperplasia, he believed, with both Dr. Smith and Dr. Baer. There is an element of passive congestion, the result of the irritation of the laceration; and when the cause is removed by the operation, the effect passes away, and the size and weight of the uterus are much decreased. He believes that preliminary treatment in cases of enlargement with ectropion has a very great effect upon the results of the operation. Applications of iodine, glycerine, and tannin, and the use of the very hot douche, and cross-hatching of the enlarged Nabothian glands, have a softening and calming effect. In such cases, if the hard, gristly triangle in the apex of the wound be carefully excised, the tension on the stitches is slight. He generally removes the sutures in about nine days after the operation; in one case, in consequence of circumstances affecting convenience, they were allowed to remain three weeks. When he can secure easy approximation and close coaptation, which is readily done by means of his guiding thread, perfect union is more probable than in any other plastic operation. For his sutures, he uses the finest possible silver wire; it is drawn to order.

As regards the results of the operation on various symptoms that were supposed to arise from the presence of the injury, he has experienced the greatest success and great disappointments. In some, local treatment would have answered every purpose.

DR. A. H. SMITH knows well the value of preliminary treatment and employs it faithfully, but there is a limit to the endurance of a patient; she cannot be kept too long upon her back, and it sometimes becomes necessary to operate before all that is possible has been accomplished. In some cases there is an unavoidable tension, and in others a friable condition of the tissue which is benefited by leaving the stitches in position. He allows the patient to attend to her domestic duties with the sutures *in situ*. In his experience there has been no relation between the number of children and the tendency to carcinomatous degeneration. Such growths have been in women who have had but one or two children only. Cancer of the mammary gland is most common in sterile women or when children have been few. He has rarely seen cancer in its early stages in an enlarged cervix with ectropion, but on the contrary in unnaturally small cervices.

DR. WHARTON SINKLER has three patients who have been operated upon for lacerated cervix, one of them by Dr. Goodell. All of them have since become pregnant.

DR. MONTGOMERY remarked that one-sixth of the cases he had operated upon (within four years) had since become pregnant. He thinks Dr. Smith's suggestion an over-true one. As the injury was the result of pregnancy, the risk must not be run again. In the Philadelphia Hospital he has found cancer of the uterus most common after numerous labors. The same rule has held good in mammary cancer. It has been most common after frequent nursing. Uterine hyperplasia is reduced by operating on the torn cervix. He has operated with this result in view in cases of so-called subinvolution. It has been recommended to divide the cervix, and remove a wedge-shaped piece, reuniting the wound, as a remedy for this condition.

DR. H. BEATES has performed twenty-three operations, and has had two pregnancies since. He has had under his care seven cases of uterine carcinoma,

and in all of them cervical laceration coexisted. The number of children varied from one to several.

DR. BAER, in closing the discussion, remarked that in answer to a letter of inquiry to the husband of a patient upon whom he had operated to restore the cervix, he received one in which the idea of another pregnancy was scouted with disdain. This is doubtless a more or less general feeling. Patients have not complained particularly of nausea in subsequent pregnancies. Hyperplasia in cases of long standing where the muscular tissue has been replaced by fibrous tissue have remained large, very little or no absorption having been effected. New cases were more benefited where the uterus was more muscular in its composition and the enlargement was due to engorgement.

Sutures were removed in from eight to twelve days; he was afraid to leave them longer on account of fear of irritation and their cutting out. It might be good to leave them longer if a seton effect were desired.

NEW YORK SURGICAL SOCIETY.

Stated Meeting January 23, 1883.

DR. F. LANGE presented a specimen of

DERMOID CYST OF THE RIGHT OVARY,

removed from a patient thirty years of age. It contained a large mass of hair and some bone. One portion presented an appearance almost exactly like a piece of the scalp, and it was from this part that the hair took its origin. There had been a variety of opinions with reference to the nature of the tumor, but for the most part it was regarded as a solid growth, and in close connection with the uterus. At the time he saw the patient it had become quite clearly established that the tumor contained considerable fluid, and that probably the uterus had been entirely crowded to the left side, and that the growth did not have its origin in that organ. It seemed by internal examination that the tumor was situated in the broad ligament. The operation was very difficult in consequence of the absence of a pedicle, and the presence of extensive adhesions. Many ligatures were applied to the adhesions, which were cut in each instance by the actual cautery, and the wounds were powdered with iodoform. Although the operation lasted two hours, the loss of blood was insignificant. The left ovary was also removed, on account of cystic degeneration. It was of about the size of a small hen's egg. Scarcely any reaction followed the operation; at no time did the temperature rise above the normal. He thought that the patient was out of danger. The operation had been performed eight days. It was the second dermoid cyst which he had removed within the last three months. The former was from a girl nineteen years of age. [At the time of this note the patient is out of bed and danger.]

STRAIGHT URETHRAL SOUNDS.

DR. POST presented several samples of straight steel sounds for treating strictures in the straight portion of the urethra. The advantage claimed for them was that they could be used with greater facility than the curved instruments, and that when given a rotary motion they caused less pain. One was fusiform in shape. They measured twenty-five centimetres in length, twenty-seven millimetres in circumference round the bulb, thirty-four millimetres at a distance of seven centimetres from the bulb, and thirty millimetres twelve centimetres from the handle.

A SUBSTITUTE FOR THE TRACHEOTOMY TUBE.

DR. L. A. STIMSON said that since the last meeting of the Society, at which Dr. McBurney read a paper on tracheotomy as a preliminary operation, he had had a patient under his care with a tumor of the superior maxilla, and it had occurred to him that possibly a substitute could be devised for the tracheotomy tube, consisting in a tube to be introduced through the mouth into the pharynx, the space around it to be blocked with sponges in a manner which would prevent the passage of blood into the pharynx, air passages, or œsophagus. After talking the matter over with Dr. McBurney, who had conceived the same plan independently, and following Dr. McBurney's suggestion with reference to details, an apparatus was constructed which consisted of a tube six or seven inches in length, and the diameter of a No. 38 urethral sound, about an inch and a half of its extremity curved to almost a quarter of a circle, and provided with a flange one-eighth of an inch in breadth, perforated with small openings through which threads could be passed. About that curved portion he tied a sponge, stitching it fast to the flange and placing behind it a piece of impervious tissue, in order to favor the retention of such blood as might soak through the sponge. After complete anæsthesia had been produced in the usual manner, the tube was passed into the mouth and carried well down behind the root of the tongue, but it caused so much gagging that it was necessary to withdraw it until it reached only a little behind the uvula, so that the patient still breathed partly through the nose. While the preliminary incision was being made and the flaps directed up, sponges were placed between the teeth, and the packing proved very satisfactory indeed. The patient was able to breathe; anæsthesia was maintained without difficulty through this tube, and although he bled very freely the sponges caught all the blood, and it was only necessary to change them as soon as filled. After the flaps had been dissected and bleeding points secured, the hemorrhage was inconsiderable. During the piecemeal removal of the growth, which included all the right and a portion of the left superior maxilla, and left a cavity which opened into both nostrils and backwards into the pharynx above the soft palate, there was no trouble whatever from the bleeding. Sponges were kept behind the surface of section and caught all the blood. The tumor was an ordinary carcinoma, and the only point concerning it which was remarkable was the fact that it had so affected the gum corresponding to it that a small fragment snipped off for microscopical examination presented all the appearance of epithelioma, even to the completely formed nests of cells. This appearance of epithelioma was due to secondary change of the papillary layer of the gum. The true tumor itself was an alveolar cancer, which had evidently originated farther back and in the substance of the bone.

Dr. Stimson said that he was aware that tubes had been devised to pass into the trachea, but that was not the intention in his apparatus. It was his intention that it should not pass beyond the pharynx. The suggestion was so simple that he thought it must have been acted upon by others, and he had shown the instrument to the Society in the hope that further trials might be made with it which would increase its efficiency.

NECROSIS OF A COSTAL CARTILAGE.

DR. J. C. HUTCHISON presented a portion of the cartilage of the eighth rib, removed from a man fifty years of age, who two years previously had typhoid fever which lasted for a considerable time. Six months later he had two abscesses over the cartilage of the rib, one at the junction of the cartilage with the rib, and the other where the cartilage joined the sternum. A probe reached the cartilage very readily, and during the last

two months he had been able to push the probe apparently into the cartilage. Lately the patient had suffered considerable pain, especially upon coughing, and Dr. Hutchison determined to remove the diseased portion; which he did by making an incision directly over the cartilage. The perichondrium was separated from the cartilage, and a chain saw carried about it, near the point where it joined the rib, very readily, and he subsequently discovered that there was separation at that point. The cartilage at the point where it joined the sternum was easily snapped off. On examination he found that the disease was confined to the anterior portion of the cartilage. He however removed the portion which remained, so that the entire cartilage was removed. The end of the rib was perfectly healthy. The case was the only one which had fallen under his observation of disease of cartilage of the rib.

NEURALGIA OF THE INFERIOR DENTAL NERVE FOLLOWING FRACTURE OF THE LOWER JAW.

DR. STIMSON narrated a case in which the patient, after the lapse of seven months, suffered from neuralgia following fracture of the lower jaw. The fracture was on the left side, and united with some displacement. The patient returned to him in December, complaining of numbness and sensitiveness in the region of the cutaneous distribution of the inferior dental nerve, and also of inability to properly masticate, because of displacement of the jaw. Dr. Stimson found that the difficulty in mastication was due to depression of the anterior fragment, and he relieved it by gouging away a portion of the posterior fragment which interfered with an upper molar. The union between the fragments was fibrous, and a temporary increase of the slight mobility followed the operation. The pain increased afterward to such an extent, although it was temporarily relieved by the use of an interdental splint, that the patient returned, and demanded some operation for her relief; pain upon pressure over the mental foramen was acute, and also along the course of the inferior dental nerve before its entrance into the canal. He exposed the nerve before its entrance into the canal by the usual incision within the mouth, and raised it up and divided it. He desired to exsect a portion, but was unable to hold it with the forceps so as to remove a portion. Relief was immediate and complete for perhaps ten days, but sensitiveness then again began to return in the region of the nerve, just where she formerly complained of it when the mental foramen was pressed upon.

DR. HALSTEAD referred to a case in which he excised about one centimetre from the inferior dental nerve. The neuralgia was severe, but relief was given; he found exsection of a portion of the nerve very difficult to perform.

DR. STIMSON referred to a case in which Dr. Sabine had divided the inferior dental nerve for the relief of neuralgia, and in which Dr. McBurney subsequently removed a portion of the nerve. The excision was followed by a cure which existed for one year.

DR. HUTCHISON referred to two instances in which he succeeded in curing obstinate neuralgia by ligature of the carotid artery.

DR. LANGE referred to a case already reported to the Society, in which the patient had had a variety of operations performed, with a varying amount of relief, but permanent relief had not yet been obtained.

DR. STIMSON remarked that the traumatic origin of the neuralgia in his case, seemed to him to be sufficient to justify the division of the nerve above the point of irritation.

NEW INVENTIONS.

A MODIFICATION OF JARVIS'S ÉCRASEUR, AND AN INSTRUMENT FOR REMOVING NASAL POLYPI.

BY FRANCKE H. BOSWORTH, M.D.,

OF NEW YORK.

IN the report of a paper on "Tumors in the Nasal Passages," read before the New York Academy of Medicine on January 4th (see THE MEDICAL NEWS, January 13, 1883), reference was made to two new instruments, the illustrations of which are herewith presented.

Fig. 1 represents a modification of Jarvis's snare écraseur, by which it can be used in the vault of the pharynx for the removal of adenoid growths, fibromas, and other neoplasms. It is to be fitted with No. 5 steel

FIG. 1.

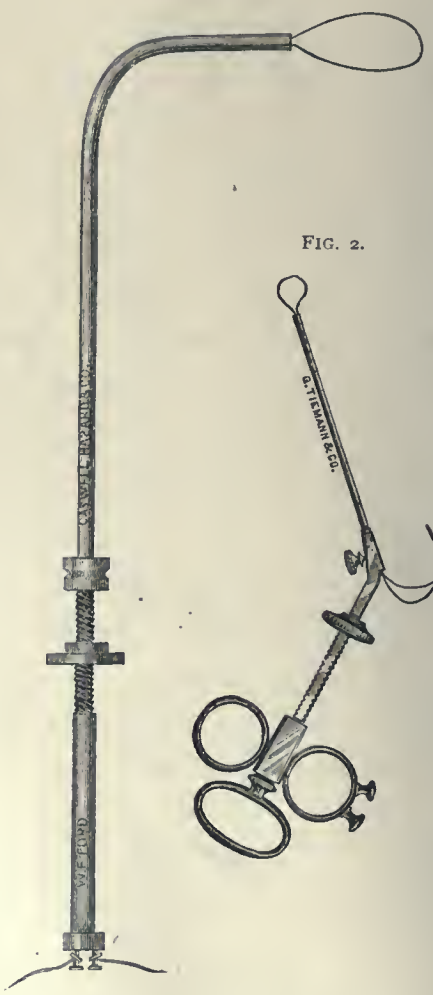

FIG. 2.

piano wire, the loop being prepared of such a size as an ocular inspection of the growth shows will easily embrace its circumference. The loop should be first bent backward from the handle, and to a right angle with the orifice of the tube. The wire is then played out about an eighth of an inch, and the wire again bent sharply toward the hand, and to a right angle.

In this position the loop can easily be passed behind the palate and to the pharyngeal vault. The action of the kinks given the wire will now be seen. As the hoop is drawn into the tube by the screw, it is thrown sharply and firmly back against the growth, and made to embrace it, while at the same time it engages the mass and severs it. The steel wire is so firm and resisting that it can be thrown with considerable force against even a broadly sessile growth, and made to engage it. I have used this device in a very large number of adenoids, as well as in fibroid and sarcomatous tumors, with such unvarying good results, that I regard it as by far the most satisfactory instrument in use for operating in the pharyngeal vault.

Fig. 2 is an instrument for use in removing nasal polypi. The Wilde snare in its day was the most thoroughly surgical instrument for operating upon these growths in use. The snare, however, merely embraces the pedicle of a polypus and wrenches it out by evulsion. The principle involved in the écraseur is that the pedicle is embraced and severed by écrasement. In this procedure the whole growth is removed, and at the same time some of the connective tissue fibres are drawn out from the mucous membrane; thus no polyp tissue remains from which a new growth may develop. In Jarvis's instrument—being straight—the hand interferes with inspection in such a manner as to hamper the manipulation. The instrument shown is a combination of the écraseur principle with that of the snare; a modification of Jarvis's and Wilde's instruments, in which the manipulation of the loop is entirely under ocular inspection during the operation.

CORRESPONDENCE.

THE EXPLANATION OF THE NEW YORK CODE.

To the Editor of THE MEDICAL NEWS.

SIR: I assume (perhaps erroneously) that you would not intentionally misrepresent the New York State Medical Society, that you might misconstrue, or be misinformed, but not willingly misrepresent; and therefore send you the thoughts which prevailed in that Society, and determined its action upon the question of the Code of 1882.

The people, through the Acts of 1806, 1857, and 1865, and their various amendments, announce, that they now have, and forever reserve to themselves, the right to declare, who shall exercise the rights and privileges of physicians in this State.

The Medical Society of the State of New York reaffirms the declaration of the Code of 1882, that the official formula of the official Society of the medical profession should accord with the laws of the State, the will of the people, the law-making power.

The Code of 1882 says that it is unwise for the medical profession of the State of New York, to attempt to misstate or misrepresent any portion of the medical law of the State, by which that profession is governed, and therefore does not attempt to deprive members of the profession of 1857 and 1865, of their rights as physicians.

We say that the people have said that those men are physicians, and we say nothing more. We endorse no societies, we endorse no men, no practices, and no doctrines. We simply maintain our right to give our advice whenever and wherever the people want it.

The American Medical Association asks us to make war upon the State of New York, and our Society votes that it has no relish for such an enterprise.

The above were the prevailing sentiments of the recent meeting, and by comparing them with your editorial in THE NEWS of the 10th inst., you can easily see how fairly you represent the situation.

Sincerely yours,

H. R. HOPKINS.

BUFFALO, Feb. 13, 1883.

[We thank our correspondent for his courtesy in parenthesis, but being still not in his mental attitude on this subject, must risk further charges of misrepresentation. Some new line of argument was needed on his side of this movement, and this one is new. Were the statements upon which it is based, and which are given as facts, somewhat nearer to being facts, the argument would have more force. When the real facts are better considered by our correspondent, he may find that his charges of misconstruction apply better to himself.

The Acts of 1806, 1857, and 1865, and their various amendments, were not made by the people, nor at the suggestion of the people, but by the petition of the bodies whose interests they represent, for the regulation and incorporation of these bodies, and for the welfare of the people through the suppression of irregular practice and quackery, and to invoke them now in support of a levelling affiliation is to misconstrue them, because it reverses their original purpose and intent. They are all laws of the people, deriving their powers from the people for the good of the people. But they originated not with the people but in the bodies they incorporate, and, as they one after the other traverse each other, as far as the good of the people is involved, they are inoperative, excepting, perhaps, the original one, which, though emasculated, was never repealed. This law of 1806, "for the purpose of regulating the practice of Physic and Surgery," incorporated the medical profession of the State "to contribute to the diffusion of true science," and hence it was for the *regular* profession.

The law of 1857 was "To incorporate Homœopathic Medical Societies," and that of 1865 was for the incorporation of Eclectic Medical Societies, and nothing is said in either of these two simple acts of incorporation about the purposes for which they were incorporated, but they are based upon the original law of 1806, and have "All the powers, privileges, and immunities now conferred by law upon the State Medical Society," and county medical societies. The purpose, so far as the welfare of the people is concerned, is the same in all three, namely, to suppress irregular practice or quackery through the incorporate existence of "true science." Therefore, as to each one the other two became irregular, or are based on untrue science—that is, quackery—and, as each one contradicts the other two, two must be void, for the people cannot enact laws to their own hurt, and the powers granted reside only in the first or original law.

Now, if the Code of 1882 attempts to harmonize these three conflicting laws by bringing into force the two inoperative ones, it is equally objectionable from the standpoint of any one of the three, and its action is impossible from the standpoint of greatest good to the people as the law-making power. Beside, the people have not said that all "those men are physicians." They have said, in the first law of 1806, that *these* are physicians, and constitute the profession, and are to be regulated for specific purposes as stated; but the others are simply incorporated for purposes not stated, but with the powers and rights of other corporations.

When the advocates of this no-code movement say they endorse no societies, no men, no practices, no doctrines, this can only be true in the sense that by demolishing all differences that have hitherto existed between societies, men, practices, and doctrines, they

really endorse all. What the progress of truth has differentiated from error, they destroy, and substitute a communism; and this, like all other communistic license, is done in the name of "liberty" and "the people."

The American Medical Association has not asked "us" to make war upon the State of New York, even by implication, for it has asked nothing at all. It is a voluntary association, like all others would soon have to be if official legal existence was permitted to dragoon them into unwholesome and incompatible fellowship, and as a voluntary association it simply declined an incompatible fellowship; therefore, the votes of "no relish" were rather irrelevant.

As the line of argument of our correspondent was not reported from the late meeting of his State Society, we are at a loss to know how he ascertained that it was the prevailing sentiment. We hope he may be mistaken.—ED.]

THE ETIOLOGY OF SWINE PLAGUE.

(*Infectious pneumo-enteritis of the pig, Klein; le rouget ou mal rouge des porcs, Pasteur.*)

To the Editor of THE MEDICAL NEWS.

SIR: In a recent communication[1] (December 4, 1882) to the French Academy, Pasteur gives the following summary of results obtained in an experimental research relating to the above-mentioned disease:

"I. Swine plague (*mal rouge des pores*) is produced by a special *microbe*, which is easily cultivated outside of the body of the animal. It is so minute that it may easily escape observation, even the most attentive. It most nearly resembles the *microbe* of fowl cholera, its form being that of the figure 8. But it is smaller and less easily seen, and differs essentially from the *microbe* of fowl cholera in its physiological properties. It has no action upon fowls, but kills rabbits and sheep.

"II. When inoculated in a pure condition into pigs, in quantities almost inappreciable, it promptly gives rise to the disease and to death, the symptoms being the same as in spontaneous cases. It is especially fatal to the white race (improved breed, most highly valued by those who raise pigs).

"III. In 1878 Dr. Klein, of London, published an elaborate research upon this disease,[2] which he calls infectious pneumo-enteritis of the pig; but this author has been entirely mistaken as to the nature and properties of the parasite. He has described a bacillus with spores as the *microbe* of this disease, which he describes as being even larger than *Bacillus anthracis* (*la bactériche du charbon*). This is very different from the true microbe of swine plague, and has no relation to the etiology of the disease.

"IV. After assuring ourselves, by direct proof, that the disease does not recur, we have succeeded in inoculating it in a mild form, and the animal has subsequently proved to be protected against the malignant form of the disease."

Néguin[3] and Salmon[4] had previously reported their failure to find the bacillus of Klein in the blood and other infectious fluids obtained from animals sick with this disease, and the constant presence of a minute micrococcus apparently identical with that described by Pasteur.

The experimental study of the last-named writer is an admirable one, and would doubtless have attracted more attention, both at home and abroad, if the work had been done anywhere else than in America. "Can any good thing come out of Nazareth?" I have seen no reference to this work in the medical journals, although the original research of Dr. Klein was extensively noticed, and was considered by many as establishing the parasitic nature of the disease in question. This deduction is sustained by Pasteur's investigations, but there can be little doubt that Klein overlooked the real parasite, and that his bacillus was developed *post-mortem*, and had nothing to do with the virulent properties of the fluids in which it was found.

Dr. Salmon says: "Virus sent me by Dr. Detmers in a liquid form still contained many such *bacilli* as he has described, and also a considerable number of both oval and spherical particles, which I considered as bacteria spores. But inoculation proved that this liquid was no longer a virus, that it had lost its activity by putrefaction, *though the septic rods supposed to be peculiar to the virus were still retained* and by their movement demonstrated their vitality. Again, cotton saturated with pleural effusion and dried by the same gentleman, was placed in a clean beaker and moistened with distilled water; in less than an hour this water swarmed with *bacilli*."

In warm weather putrefactive organisms develop with astonishing rapidity in the blood and tissues of animals dead from any acute infectious disease. These organisms are constantly present in the intestine of healthy animals in vast numbers, and it may be that in these diseases, owing to the very slight vital resistance offered in the last moments of life by the mucous membrane of the intestine, to the dilatation of its capillary bloodvessels, and to loss of its epithelium, putrefactive bacteria find their way into the almost stagnant blood in the mesenteric veins, and even into the general circulation before life is extinct.

Be this as it may, the rapid *post-mortem* development of these organisms after death from any septic disease cannot be questioned; and one who undertakes to pursue etiological investigations is likely to be misled, notwithstanding that he may be an accomplished pathologist and a skilful microscopist, unless he resorts to methods which enable him to exclude with certainty this source of error, as well as that arising from the presence in the atmosphere of the germs of these same organisms.

Dr. Salmon has given an account of his method of collecting blood from the veins of an animal just killed, in hermetically sealed and sterilized—by heat—glass tubes. (*Loc. cit.*, p. 396.)

The method seems to the writer to be entirely trustworthy, and the record of experiments made inspires confidence in the scientific accuracy of the observer.

Blood drawn from the veins of a pig affected with swine plague, into these "capillary vacuum tubes" was quite free from bacilli at the end of ten days. But this blood swarmed with micrococci, single, in pairs (Pasteur's figure 8), in chains, and in zoöglœa masses.

Healthy pigs inoculated with this blood sickened at the end of seven days and exhibited the characteristic symptoms of the disease. These inoculations did not, however, produce a fatal form of the malady, and Dr. Salmon found it "impossible to carry the virus beyond a second generation, even by inoculating pigs which had never before been exposed to the contagium.

Inoculations with cultivated virus, containing the micrococcus in abundance, produced a discoloration of the skin, and a slight eruption; but the symptoms were not sufficiently definite to enable the experimenter to say with certainty that the inoculated animals suffered a mild attack of the disease.

It is to be hoped that the Agricultural Department will continue to foster experimental studies of this kind and that Dr. Salmon may have further opportunities for the study of this and other infectious diseases

among our domestic animals. No doubt liberal appropriations can be obtained for this purpose on account of *pecuniary* losses which our agricultural *voters* suffer from these diseases.

Respectfully,

GEORGE M. STERNBERG, M.D.,
Surgeon, U. S. Army.

FORT MASON, SAN FRANCISCO, January, 19, 1883.

THE EFFICACY OF CARBOLIC ACID IN ODONTALGIA.

To the Editor of THE MEDICAL NEWS.

SIR: Feeling it to be the duty as well as the privilege of every physician to make known to the profession the utility of any agent which he may have found beneficial in relieving pain or curing disease, I send you my experience in relation to carbolic acid as a remedy for toothache arising from caries.

About three months since I was distracted with toothache for about twenty hours, during which time I tried all the known remedies, but in vain. At last it occurred to me to try pure carbolic acid, and although at first I felt a little diffident, having never heard of its use in this way before, I applied it, and, to my great relief and agreeable surprise, the pain ceased instantly, and did not return.

Having to deal with a large number of the poor in my dispensary practice, I have rejoiced in being able to afford similar relief to many sufferers. One poor woman, in an advanced state of pregnancy, had not enjoyed a night's rest for nearly two months; but after a little patient application I was able to send her away rejoicing, and I have not heard of the tooth troubling her again.

Desiring that others may share in the luxury of *doing good* in this way, as well as receiving relief, I append the *modus operandi* adopted.

1st. Clean out and dry, by means of absorbent cotton, the cavity of the tooth.

2d. Apply the acid thoroughly in the following manner: Take a piece of *wood*, according to the size of the cavity (a toothpick or a match will do), and dip the end into carbolic acid—*full strength;* should the hole be very large, a very small portion of cotton may be twisted around the end of the piece of wood. Care is required not to touch the surrounding tissues. It is scarcely needful to add that the acid crystals only need to be warmed to render them soluble.

The foregoing applies especially to odontalgia cariosa, and to odontitis; but it will also prove serviceable where the fangs of the tooth are affected, especially if they are accessibly exposed. I am, dear sir,

Yours respectfully,

GEORGE D. DOWKONTT, M.D.,
Med. Supt. N. Y. Medical Mission.

NEWS ITEMS.

WASHINGTON.

(*From our Special Correspondent.*)

AMERICAN PUBLIC HEALTH ASSOCIATION.—On Friday, February 16, the Executive Committee of the American Public Health Association met at the Naval Museum of Hygiene, in Washington, D. C. It was decided that the principal topics for discussion at the next meeting of the Association should be—1. The best methods of collecting and publishing vital statistics. 2. The etiology of malaria. 3. Food preservation and adulteration; and, 4. the physics of house drainage. The next meeting of the Association is to be at Detroit, and the time fixed by the Committee is the second week in November, which seems rather late in the season for that locality.

TROY, N. Y.

(*From our Special Correspondent.*)

THE RENSSELAER COUNTY MEDICAL SOCIETY AND THE NEW CODE.—At the stated meeting of the Rensselaer County (N. Y.) Medical Society, held on February 13th, the Society voted to stand by the Code of the American Medical Association and elected delegates to the Association. The County Society thus takes open issue with the State Society.

CHICAGO.

(*From our Special Correspondent.*)

THE CHICAGO TRAINING SCHOOL FOR NURSES has issued its second annual report, showing a satisfactory progress. The school began in 1881, has now twenty-three admitted pupils, and eight on probation, employed in seven wards of the Cook County Hospital. The staff of the hospital expresses its full satisfaction with the conduct of the nurses. The institution is soon to have its own home in a building now in the course of erection in the vicinity of the hospital.

FLORIDA.

(*From our Special Correspondent.*)

THE YELLOW FEVER AT PENSACOLA.—An epidemic of yellow fever prevailed in Pensacola and vicinity during the summer and autumn, 1882, about 2,400 cases of the disease, with nearly 200 deaths, being recorded within the 86 days of the scourge.

The naval reservation, containing some 1,600 acres, is situated on Pensacola Bay, about four miles to the southwest of the city. It had a population of some 1,700 people during the fall, and although the disease spread through the surrounding country, so as to include the station named, not a case of the fever appeared within its limits, owing to non-intercourse—an armed picket-line keeping out all persons from August 28th until November 23d, when frost came to the relief of all concerned.

Upon the official announcement—August 28th—that yellow fever existed in Pensacola, the unacclimated officers, with two exceptions, and all their families, as well as the marines, left the yard for other parts, agreeably to the recommendation of the senior medical officer of the station. As the marine guard consisted in the main of recruits enlisted at the north, and who were not even inured to a soldier's life, it was judged prudent not to place them on picket duty. Moreover, from experience gained in past epidemics of the said fever at this station, as recorded in official and other reports, it is known that the marines were among the first to be seized by the disease. At all events, it was thought wise to get rid of this element of danger at the outset.

The employés of the yard, numbering about eighty men, all acclimated, were immediately organized into a cordon, and placed around the entire reservation, with orders to permit none to enter the lines, upon any pretext. The said line was over four miles in extent, more than half being water-front, and thus easily guarded. At first these sentinels were without any shelter, save what could be obtained from hastily improvised structures of bushes, and there was, necessarily, some irregularity relative to their reliefs. But in a few days *A* tents were pitched along the lines, and a swath some thirty feet wide was cut through the woods and thickets, to give an unobstructed view, as well as a clear beat. The roads for the most part

were blockaded by abatis, to prevent thoroughfare. A part of the regular watchmen of the station were encamped on the road communicating with Pensacola at the extreme northeasternmost extremity of the reserve, and here the incoming mails were fumigated, and the outgoing bags delivered.

On the 16th September, by request, the citizens of the reservation volunteered to come to the aid of the naval authorities, to help maintain the cordon; and to this end all the males above the age of sixteen years were enrolled for picket duty, to the number of about four hundred. No one was excused from this service, unless some physical disability prevented locomotion. All officers had to stand guard, or pay a substitute, no exceptions being made.

The posts were systematically numbered. Each day, those whose turns of duty had come were notified of the fact, and two men were told off for each post. These pickets were allowed to arrange to suit their own convenience as to how they would stand their twenty-four hours' guard. All the sentinels were visited at stated times, day and night, by officials appointed for this work. As all the guards had interests at stake, in protecting their families and friends from the enemy, no great trouble was experienced in keeping the men up to the work. However, when the disease began to spread in the neighborhood of the lines, there were some annoyances and difficulties in maintaining the quarantine inviolate, as a part of those who had taken refuge in the immediate vicinity when the malady was first made known as in Pensacola, now desired to return to their homes on the reserve, for greater safety. Of course, this could not be permitted; and thus a conflict of interests arose. But the quarantine was held, in spite of all the attempts to break it.

As the station was thus effectually closed against the surrounding country, and in its turn was cut off from all the world—save by sea—the only avenue by which to obtain provisions was from Mobile, some seventy miles distant. Upon several occasions, the board of health of that city, upon receiving a certificate from the surgeon of the naval reservation that there was and had been no case of yellow fever, and no symptoms of any contagious or infectious disease within the cordon, and that a rigid quarantine was maintained against Pensacola and vicinity, permitted a steamer to visit the station, for the sole purpose of supplying provisions. Had the said authorities refused to grant this boon, the quarantine could not have been kept up, as the inhabitants would have been starved out early in the fall.

Three times during the blockade rumors circulated that the malady had appeared among the pickets and others, but happily such was not the fact, congestive remittent fever being the disease which gave rise to these reports and the attending uneasiness. It may be stated that the epidemic, as it existed in Pensacola, was by no means the mild type, as is generally supposed by those who know of it merely by reading the daily or common reports. In point of fact, the opposite is the truth; the statistics, as now published, to the contrary notwithstanding. From Aug. 10th, the date of the first appearance of the fever in Pensacola, until August 28th, inclusive, when the disease was officially made known, and the city was shut out from the rest of the country, a large portion of the unacclimated populace made its escape, with or without the advice of the board of health.

Now, of the stated 2,400 cases, fully one-half were among the colored residents, of whom only one per cent. died. Of the white inhabitants, many of whom were Germans and Italians, too poor to get away, a majority were seized with the disease. It is safe to say that, with very few exceptions, all those unprotected by a former attack of the affection, suffered its presence personally. Of those who had had the fever, and were attacked again, all recovered. With the Germans the percentage of mortality was over seventy, and among the Italians it was a little less. The newcomers, in general, suffered to the extent of over forty-five per cent. From the fact that the colored population was so generally taken with the fever, it is judged by competent authorities present that the type of the disease was malignant.

It is quite evident, to those who have studied the history of the epidemic, that the malady was brought to Pensacola by infected shipping, through the lazaretto of the city. It is thought that the precise way it reached the shore there can be given positively, with all the dates and figures necessary to convince all interested of the fact. And it is believed there that, with a proper quarantine, yellow fever will no longer be the bugbear of that beautiful bay.

WINNIPEG, MANITOBA.

(*From our Special Correspondent.*)

THE medical men of this city have organized a medico-chirurgical society with Dr. Lynch *President*, Drs. Whiteford and Codd *Vice-presidents*, Dr. Covernton *Secretary*. *Council*, Drs. O'Donnell, Patterson, Jack, Brett, Philip, and Kerr.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—The Board of Trustees held a meeting in Chicago, on January 17. A majority of the members were present, and communications relating to the more important questions to be discussed were received from all the members not present. After a full examination of the whole subject, it was unanimously decided to report to the next meeting of the Association in favor of the establishment of the proposed journal. Steps were also taken to have all the preliminary arrangements so far matured that the first issue of the journal could be made within thirty days after the next meeting, provided the Association should adopt the recommendation of the Board. While the members of the Board were satisfied that the present number of returned pledges afforded a safe basis on which the Association might commence to publish the journal, they deemed it very desirable that more should be added to the list before the time for making their report, that there might be no reason for doubt or hesitation on the part of the Association when it should be called upon to take final action on the subject.

THE APPROPRIATION FOR THE PREVENTION OF THE SPREAD OF EPIDEMIC DISEASES.—The Sundry Civil Bill as reported to the House contains a clause appropriating $100,000 in aid of State and local Boards of Health in preventing the spread of epidemic diseases. Mr. Manning offered an amendment providing that the money shall be expended under the supervision of the National Board of Health. Mr. Ellis, of Louisiana, in opposing the amendment expressed his opinion that the National Board of Health was the most stupendous humbug and fraud ever created, and quoted from its own report to show that it had made misexpenditures of the public money. He could bring home to that Board a deliberate attempt to create rumors of yellow fever in New Orleans.

Mr. Dunn, of Arkansas, advocated the amendment, and declared that the Louisiana State Board of Health concealed the existence of pestilence in New Orleans, and was willing to peddle death through the country in order to keep up the commerce of the State. Mr. Manning defended the National Board of Health from

adverse criticism, and reflected upon the Louisiana State Board, attributing to it in great measure the yellow fever epidemic of 1878. After further discussion the amendment was lost.

THE NAVAL MEDICAL SOCIETY.—The officers of the Medical Corps of the United States Navy, have formed a Medical Society, which will hold meetings on the first Thursday of every month in Washington.

At the annual meeting held January 4, 1883, the following officers of the Society for the current year were elected:

President.—Albert L. Gihon, M.D.
Vice-President.—John M. Browne, M.D.
Secretary.—James M. Flint, M.D.
Business Committee.—Thomas J. Turner, M.D., Adolph A. Hoehling, M.D., Thomas H. Streets, M.D.

THE AMERICAN JOURNAL OF OTOLOGY.—The suspension of this publication is announced.

A CÆSAREAN OPERATION PERFORMED BY A PRIEST.—M. BLOMME, according to the *Lyon Méd.*, January 28th, the *curé* of St. Amand, Belgium, was called to one of his lady parishioners who seemed on the point of death and was far advanced in pregnancy. Seeing that the woman was lost, and having in vain sought for a medical practitioner or midwife, he resolved to remove the fœtus himself, and succeeded in extracting twins—the subject of the operation having in the meantime died. He was proceeded against for illegal practice of medicine, but the case was dismissed, and an appeal being made to the Tribunal at Ghent, it confirmed the acquittal of the accused, on the ground that what he had done did not come under the operation of any penal law. The Procureur-Général of the Ghent Appeal Court gave notice that he should take the case into the Cour de Cassation.—*Med. Times and Gazette*, February 3, 1883.

COMPULSORY VACCINATION IN GERMANY. — DR. ROBERT KOCH has expressed himself strongly in favor of the present movement in Germany, which proposes compulsory vaccination. He thinks the dangers of transmitting syphilis and scrofula are almost infinitesimal.

STATUE TO DARWIN IN FRANCE.—Acting on the proposition of M. de Quatrefages, the Academy of Sciences of France have authorized the opening of a subscription for the erection of a monument in honor of the memory of Charles Darwin.

AN ARMY MEDICAL BOARD has been ordered to assemble at the Army building, corner of Houston and Greene Streets, New York City, New York, March 1, 1883, for the examination of such persons as may be properly invited to present themselves before it as candidates for appointment in the Medical Corps of the Army, and will probably continue in session about three months.

All candidates for appointment in the Medical Corps must apply to the Secretary of War for an invitation to appear for examination. The application must be in the handwriting of the applicant, must state date and place of his birth and place and State of which he is a permanent resident, and must be accompanied by certificates based on personal acquaintance from at least two persons of repute as to citizenship, character, and moral habits. Testimonials as to professional standing from professors of the medical college at which they graduated, should also accompany the application if they can be obtained. The candidate must be between twenty-one and twenty-eight years of age (without any exceptions), and a graduate of a regular medical college, evidence of which—his diploma—must be submitted to the Board.

Further information regarding these examinations and the nature thereof, can be obtained by addressing the Surgeon-General, U. S. Army, Washington, D. C.

NATIONAL BOARD OF HEALTH.—At a meeting of the Michigan State Board of Health, at Pontiac, Michigan, February 1, 1883, the following resolutions relative to the National Board of Health were adopted:

Whereas, The work of the National Board of Health has been seriously crippled by reducing its appropriation and by transferring to another branch of the government service important parts of its legitimate work and means of usefulness,

Resolved, That in our opinion, no other government service is so well qualified to perform the health service of the United States as is the National Board of Health, which has shown by its works its ability to do what was assigned to it, and to gain and retain the confidence of sanitarians throughout this country.

Resolved, That we consider it of the highest National importance, as also of great importance to this State, that the National Board of Health shall receive annually an appropriation sufficient to enable it to carry on the important work of protecting the country from the introduction of contagious diseases; of collecting and distributing, for the guidance of State and local boards of health, information relative to the prevalence of diseases, and particularly of contagious diseases; of investigating by specially qualified experts the obscure causes of diseases; and of publishing to the world the results of its studies and investigations, more especially concerning diseases which, like diphtheria and smallpox, spread generally throughout the country.

Resolved, That a copy of this preamble and resolutions be forwarded to each member of Congress from this State.

The Illinois State Board of Health furnishes the following memorandum of the work performed by the National Board as an argument for its continuation: The National Board of Health has demonstrated the value and efficiency of the national authority in the protection of the public health. By initiating a reform in the principles and practice of maritime quarantine, which, so far as it has been carried out, has resulted in securing the largest measure of protection against the importation of foreign pestilence on the one hand, whilst, on the other, it relieves commerce from the arbitrary, and often dangerous, detentions, with their consequent costly charges and exorbitant fees, which obtain under the old system, still largely in vogue.

By its service of sanitary inspection and supervision of immigrants and of inland transportation by river and rail, whereby the introduction and spread of smallpox and yellow fever have been effectually controlled; the barbarities of the "shot-gun quarantine" abolished; and commercial confidence, business interests, and travel and traffic protected against needless interruptions and loss through panic and unfounded alarm.

By its researches and investigations into the cause of yellow fever, diphtheria, malarial, and other diseases; into the adulterations of food and drugs; into the sources of, and remedies for air, soil, and water pollution; and into many other problems of sanitary science and preventive medicine, the results of which are already utilized by sanitary engineers, legislators, medical teachers, physicians, and others in promoting human comfort and well-being, in preventing disease and in saving life.

By demonstrating the feasibility of so dealing with

an infected locality—by temporary depopulation, isolation, and sanitary supervision of its relations with exposed communities—as to secure the prevention of spread of the infection; the limitation of its ravages to the fewest number of victims within the locality itself; and the minimum of disturbance to the interests of threatened regions.

By its relations to State and local boards of health, through which have been secured coöperation and uniformity of action, without regard to State and local boundaries or jurisdiction, to the great advantage of common carriers and other agents of commerce, and to the more efficient protection of the public health; and through which, also, State and local boards have been relieved, *pro tanto*, from the necessity and expense of guarding against the invasion of disease from without—a necessity for which such boards, unaided, have neither adequate authority or means.

WHAT IS SAID OF THE NEW YORK CODE.—"The net result is to impress the mind with a sense of the predominance of the commercial over the professional or scientific elements of the practice and pursuit of medicine.—*Boston Medical and Surgical Journal.*

"The disaster at Albany is due to a cause which has carried many ignoble measures in our State and municipal affairs, viz., a reluctance on the part of our ablest scientific men, who otherwise mould professional sentiment, to engage in heated controversial discussions. The meeting at Albany was not representative. The leaders of medical opinion and the acknowledged scientific authorities in New York should have been in person at Albany. The one hundred and two who protested in writing should have protested by so many votes.—*Louisville Medical News.*

"We sincerely trust that the action taken may prove to be wise, and that its effect may not in the long run act as a bar to the affiliation of our State Society with those bodies that formerly worked in harmony with it. —*New York Medical Journal.*

"The matter can now be safely left where it is. We may be permitted to say, however, in the greatest courtesy, that the present action of the Society conclusively shows that New York State is determined to take care of its own ethical affairs, and resents meddlesome interference from outside influences."—*The Medical Record.*

WHAT THE NEW YORK CODE WILL LEAD TO.—The *Maryland Medical Journal* for February 15th, concludes an editorial on this subject, as follows: "As for those members of the New York profession who still show allegiance to the National Association, but one course seems open to them, and that is to withdraw from the seceding body and organize a new society, which would join with the other State societies in upholding the principles which alone can maintain the honor and respectability of our profession in their complete integrity."

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending February 10, 1883, indicate that diarrhœa, scarlet fever, and diphtheria have increased, and that neuralgia has decreased in area of prevalence.

Including reports by regular observers and others diphtheria and scarlet fever were each reported present during the week ending February 10th, and since, at 19 places, and measles at 16 places. Smallpox at St. Joseph, Berrien County, was reported as having ceased February 10th.

OBITUARY.—DR. HENRY C. SIMMS, died at Brooklyn, on February 13th, aged 50 years.

He was a native of Washington, D. C., a graduate of Jefferson Medical College in 1855, and had been twenty-five years in practice in Brooklyn. He was elected coroner in 1874, and again in 1877, but on running for a third term in 1880 was defeated; he was one of the very few physicians of education who have been chosen to that responsible position in that city, and made one of the best coroners who have filled the office. His death took place suddenly by heart disease; an autopsy revealed partial occlusion of the coronary artery.

——Died at Philadelphia, on February 15, 1883, DR. BENJAMIN HOWARD RAND.

Prof. Rand was born in Philadelphia in 1827. He graduated from the Jefferson Medical College in 1848, and two years later was elected Professor of Chemistry of the Franklin Institute. From 1852 to 1864 he was Secretary of the Academy of Natural Sciences. He accepted the Chair of Chemistry in Jefferson Medical College in 1864, from which ill-health forced him to retire in 1877. He was elected a Fellow of the Philadelphia College of Physicians in 1853 and a member of the American Philosophical Society in 1868, and was also a member of the American Medical Association. He was the author of several elementary works on chemistry.

—— Died on January 25th, CHARLES EMANUEL SÉDILLOT, in the eightieth year of his age.

Prof. Sédillot was born in Paris in 1804, where he received his medical education, graduating in 1825; in 1836 he was made Surgeon-major in the army and served in the African campaign. In 1839 he was appointed to the Chair of Clinical Surgery in Strasbourg. His contributions to operative surgery were numerous and important. He introduced several important modifications into the methods of performing amputations and resections: he was also the author of an important work on luxations. He was one of the first French surgeons to use ether as an anæsthetic, and his essay on the retention of the periosteum as a means of preserving the value of limbs was crowned by the Surgical Institute in 1867.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 12 TO FEBRUARY 19, 1883.

BROWN, JOS. B., *Lieutenant-Colonel and Surgeon.*—Detailed as member of board for examination of assistant surgeons for promotion and candidates for admission into the Medical Corps, U. S. Army, to convene at New York City, on March 1, 1883.—*Par. 1, S. O. 35, A. G. O., February* 10, 1883.

CLEMENTS, BENNETT A., *Major and Surgeon.*—Detailed as member of board for examination of assistant surgeons for promotion and candidates for admission into the Medical Corps, U. S. Army, to convene at New York City, on March 1, 1883.—*Par. 1, S. O. 35, A. G. O., February* 10, 1883.

JANEWAY, JOHN H., *Major and Surgeon.*—Detailed as member of board for examination of assistant surgeons for promotion and candidates for admission into the Medical Corps, U. S. Army, to convene at New York City, on March 1, 1883.—*Par. 1, S. O. 35, A. G. O., February* 10, 1883.

CLEARY PETER J. A., *Captain and Assistant Surgeon* — Granted leave of absence for four months on account of sickness, to take effect January 3, 1883, in extension of his authorized absence on certificates of disability.—*Par. 6, S. O., No. 40, A. G. O. February* 16, 1883.

ORIGINAL LECTURES.

THE TREATMENT OF LUPUS.

Abstract of a Clinical Lecture.

BY GEORGE HENRY FOX, M.D.,

CLINICAL PROFESSOR OF THE DISEASES OF THE SKIN IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

IN spite of the difficulties attending the diagnosis of lupus, which I have just pointed out, the general plan to be adopted in its treatment is usually clear. Should a tubercular syphilide be mistaken for lupus, and treatment by operative measures instituted, a gross blunder would be committed. A mistake in diagnosis, however, between lupus vulgaris and lupus erythematosus, or between lupus and epithelioma, or that form of disease which is known in England as rodent ulcer, would involve no serious harm to the patient, for the treatment would be substantially the same in either case.

In each of these affections, we have a new growth in the skin, which manifests a marked tendency to spread and invade healthy tissue. The main object of treatment must therefore be the destruction or removal of this growth. When taken in its incipient stage, this can be readily accomplished. If, however, lupus has increased to such an extent as to involve a considerable amount of tissue, its successful treatment is by no means a trivial matter. Half-way measures are often worse than useless. In very many cases the attempts to heal the ulceration, or remove the nodules by daily cauterization, have only stimulated the progress of the disease. It is better to do nothing than to irritate the part by applications which tend more to inflame the healthy skin than to destroy the morbid growth. At the same time it is not always necessary, and in lupus of the face it is often unadvisable to attempt to remove the growth in a single operation. In treating lupus, our object is not only to remove the diseased tissue, but to do so in such a manner as will occasion the least amount of disfigurement. A relapse of the disease after an operation, is considered by some surgeons to reflect discredit upon the operator. But, in the treatment of lupus of the face, I think it is far better to remove the greater portion of the growth at the first operation, and to tell the patient that a second or third operation will probably be required, in order to avoid, as far as possible, the production of a disfiguring scar. Of course, if the patient desires the removal of the growth in one operation, this can be accomplished, but in many cases I should not advise it.

Formerly, it was the custom to use the knife freely in the treatment of lupus, and no one can doubt the success which was attained by this method, but the resulting scar was usually large and deep. With the means now at our disposal, it is only in rare cases that we resort to the use of the knife. When lupus invades the lower eyelid, as it frequently does, a plastic operation may be necessary, in order to fill up the gap made by the removal of the diseased tissue; but when no such indications exist, a sharp spoon or curette is an instrument of far less terror to the patient, and of far greater utility in the hands of the surgeon, than the knife. Whether we have a group of tubercles with an unbroken epidermis, or a patch of ulceration, we can remove the diseased tissue by means of a curette with the greatest ease, and with a slight amount of pain; unless the patient is aged, or weak, or has very little courage, the growth, if small or of moderate size, can be removed without the use of an anæsthetic. In cases requiring anæsthesia, nitrous oxide gas is usually preferable to ether or chloroform. The scraping operation can be performed much more quickly than excision, and while the nitrous oxide may be safely inhaled for a half-hour or more, a few minutes of anæsthesia is often all that is required, and then much time is wasted and trouble occasioned by the use of ether.

In a number of cases I have resorted to the use of local anæsthesia with good effect. By the use of an ether spray produced by means of a hand-ball, the part to be operated upon can be kept in a half-frozen and almost insensible condition. The spray at the same time washes away the diseased tissue as fast as it is loosened by the curette, leaving the surface clear and thus rather facilitating the operation than otherwise. To one who has had no experience with the use of the curette, the ease with which the morbid tissue can be scraped away is quite surprising. The lupous nodules, although feeling firm to the touch, are much softer than the surrounding skin, and are scraped out of the corium by the employment of very little force. After some experience with this instrument, one learns to recognize the peculiar sensation which is imparted to the touch, when the instrument comes in contact with perfectly healthy skin. Should no steps be taken further than scraping out the morbid growth, a relapse is almost certain to occur, especially if the disease has existed for any considerable time, and has invaded the deeper portion of the skin; it is therefore always advisable to cauterize the raw surface left after thorough scraping, or to apply some powder or paste, which will be likely to destroy the vitality of the lupous cells which may remain. Of the various caustics which have been employed, I have found the application of chloride of zinc to be most efficacious, but the pain which it occasions is a serious objection to its use. The actual or thermo-cautery has been highly recommended, but I have seen lupous nodules reappear so many times after its use, that I cannot recommend it. Pyrogallic acid in the form of a twenty per cent. ointment, I have used as an application after scraping, and with good results. A mixture of equal parts of arsenious acid and gum acacia, made into a paste with a few drops of water, is very beneficial, inasmuch as it tends to destroy only the morbid tissue; but its use is followed by severe pain, which lasts for several days. When the patch is not of long standing, and is superficial in its seat, the application of iodoform after scraping is the plan which I would recommend. It is painless, and like the arsenical paste, tends to destroy the lupous cells and promotes the speedy healing of the ulceration. If, on the other hand, the growth is of long standing, and the nodules are deeply seated in the corium, the use of a cone of nitrate of silver is, in my opinion, the best adjuvant to the curette. The point of the nitrate of silver cone should be pressed firmly in different directions into the small pits left after the removal of the nodules. This procedure will usually serve to destroy the foci of the disease, which would otherwise certainly occasion a relapse in the course of a few months.

After the removal of a patch of lupus, by means of the curette and the employment of one of the applications already mentioned, the process of healing is

usually speedy, and a tolerably smooth cicatrix will result. A relapse may be looked for at any time during the year following the operation, and should it occur, the morbid growth will appear in the form of one or more brownish-red papules springing up at the edge, or in the midst of the cicatricial tissue. A second operation then becomes necessary. But now it is comparatively a simple matter to dig out these foci of the disease by means of a curette of small size, and to thrust in a cone of nitrate of silver.

Multiple puncture and linear scarification are methods of treatment which have been highly recommended by European writers. In my opinion they are inferior to the plan of treatment by the curette and caustics, except in those cases where the disease involves the nose. Here the treatment by linear scarification is greatly to be preferred to others, inasmuch as it destroys the morbid cells by converting them into fibrous tissue without changing the normal contour of the part.

As regards the constitutional treatment of lupus, little can be done beyond a strict attention to hygienic conditions. The disease is generally regarded as dependent upon a scrofulous condition, and hence iodine and cod-liver oil may serve a good purpose. It will not answer to place much dependence upon these agents, however, as curative measures, for in some cases where cod-liver oil has been taken by the pint or half pint daily, the disease has persisted.

I cannot regard lupus vulgaris as the obstinate disease which it is generally described to be in the text-books: save in those cases where it has been neglected and has produced frightful ravages, a safe and speedy cure can be effected if the patient is in average health and the physician persevering.

Lupus erythematosus, on the other hand, is in my experience a more troublesome disease to deal with. As this affection is usually less disfiguring in its progress than lupus vulgaris, the patient is not ready to submit to surgical interference.

In this latter affection the various ointments and external remedies commonly employed have little curative effect in the majority of cases. In its mild and recent form it has been successfully treated by the daily application of green soap. The acute inflammation excited by this means causes absorption of the lupous cells. In one or two cases I have seen a patch disappear under the continual application of mercurial plaster. In many more cases I have seen this practice produce no beneficial results. I have recently applied flexible collodion containing twenty per cent. of chrysarobin, with the effect of leaving the patch in a smoother and far more healthy condition. If such mild measures are unavailing and a cauterizing agent is called for, I would recommend above all others the use of the ethylate of sodium. This blisters the skin, produces a superficial eschar, and by a peculiar effect which it appears to exert upon the bloodvessels, will remove a patch of erythematous lupus and leave a very slight cicatrix.

I have found the curette of comparative little value in the treatment of erythematous lupus, although I have successfully removed the disease by its use. The diseased tissue does not yield by any means as readily as do the nodules of lupus vulgaris, and the scraping is therefore more unsatisfactory than cauterization. As regards the internal treatment of erythematous lupus, I have little to say. The continued use of phosphorus has undoubtedly effected a cure in some cases. The iodide of starch, or *Amylum iodatum* of our new Pharmacopœia, was highly recommended some years ago. I consider this an extremely valuable remedy for a certain class of patients presenting symptoms of struma and calling for the administration of iodine. I have used this with apparent benefit to the general health in patients suffering from late syphilis and lupus vulgaris, as well as lupus erythematosus. I have not seen the latter disease cured, however, or modified in any marked degree by its administration.

IODOFORM IN FISSURE OF THE ANUS.

By BOARDMAN REED, M.D.,
PHYSICIAN TO THE SEASIDE HOUSE FOR INVALID WOMEN, ATLANTIC CITY, N. J.

Fissure of the anus generally resists all ordinary treatment short of incision or dilatation. Sometimes even these operations fail; but if they were certain to cure, patients dread them, and often insist upon first trying every possible form of treatment, rational and irrational. Therefore, considering the very painful nature of the affection, any simple measure which has given good results in a large proportion of cases should command attention. An ointment of iodoform has proved, in my hands, exceedingly useful in this disease, effecting very good results in all the cases in which I have used it, with one exception, and here I do not think it had a sufficient trial.

Before resorting to this remedy my experience with anal fissures was rather unfortunate. Healing salves of various kinds were tried, and did very little good, even temporarily. Nitrate of silver proved as painful as the knife, yet frequently—indeed, generally—failed to cure, often seeming to aggravate. Even the operation of cutting through the floor of the ulcer failed sometimes in my earlier cases. The more radical operation of dividing the sphincter entirely I never resorted to.

I have preserved notes of five cases treated with iodoform, four of which were cured by it. Two or three other cases thus treated are only indistinctly recollected, no notes of them having been kept, but they also were cured, or greatly relieved. In one case only have I found it necessary to resort to operation since beginning to use the iodoform.

Case I.—Mr. F. sent for me, at night, on account of excruciating pain in the anus. I found him suffering intensely, the pain taking a spasmodic form. There was a large inflamed external hemorrhoid, and, as an additional complication, an irritable ulcer. He had experienced more or less pain for months, but had become much worse within a few days. It was now so intolerable that a hypodermic injection of morphia and atropia was at once administered. Pieces of ice, wrapped in rags, were applied to the inflamed hemorrhoid, the only local palliative measure which I have ever found of any avail in such extreme cases. In this way comparative ease was obtained, but the injections had to be several times repeated, the spasmodic pain recurring, in a severe form, the moment the effect of the anodyne subsided. Meanwhile, moderately full doses of a mild purgative were given to open the bowels. These failed, and it became evident, from the peculiar spasmodic pain and forcing efforts, that a mass of impacted feces filled the rectum and lower bowel. Large doses of castor oil were administered, with the effect of relieving the distressing condition.

The continued application of the ice reduced the inflamed pile, but the fissure seeming to be chronic, I advised dilatation of the sphincter. While this was being considered, the following ointment was used:

℞.—Iodoformi pulv., ... ʒss.
Bals. Peruv., ... ʒij.
Cosmolini, ... ʒj.—M.
Sig. Apply three or four times a day after washing the parts.

By this combination the very offensive odor of the iodoform is much disguised, though by no means abolished. The balsam of Peru, besides its usefulness in this direction, is an efficient stimulant to the healing process.

Some relief from this application was apparent almost from the beginning, and the improvement continuing, the operation was deferred, until at the end of a few weeks the fissure was found to have healed.

Case II.—Mrs. V., aged 28, shortly after confinement with her first child, began to complain of pain in the anus, lasting for hours after each stool. An examination revealed a decided fissure. The bowels were kept open with pulv. glycyrrhizæ comp. The foregoing prescription of iodoform, etc., was again resorted to, and with entire relief. The pain was less and less complained of, and by the end of a month had wholly ceased. No further examination was made, but the symptoms have never recurred.

Case III.—Mrs. L., aged 38, an inmate of the Seaside House for Invalid Women at Atlantic City, came under my care in October, 1881. She had retroversion of the uterus, complicated with much areolar hyperplasia, and I suspected but could not positively make out some fibroid thickening of the posterior wall. She also menstruated excessively about every twenty-one days. She had been complaining for some time of a persistent pain in the anus, coming on shortly after defecation. An examination revealed a fissure. Regular evacuations were procured with the pulv. glycyrrhizæ comp.—later with cascara sagrada—and the iodoform ointment was applied frequently. Relief was prompt, and at the end of two months the fissure was found entirely healed. Owing to the condition of her uterus, which resisted every form of local treatment, there was a constant tendency to congestion of the adjacent parts, and at times even after the fissure healed she complained of some dull pain in the rectum after stools, which she always found remedied by the use of the same ointment. She passed from under my care last June, when Dr. Wm. H. Bennett relieved me for the summer term, and had left the house before I went on duty again; but I cannot learn that the fissure has ever broken out anew, notwithstanding the continual existence of such a strongly prediposing cause. It may not be amiss to add that local treatment by applications of iodine, carbolic acid, etc., to the cervix and cavity of the uterus seemed only to aggravate the disease of that organ in this singular case, especially the one symptom of menorrhagia; yet the prolonged influence of sea-air and rest, combined with the use of tonic and restorative medicines, afterward greatly benefited that rebellious symptom, at the same time that her general condition was in every way improved.

Case IV.—Mrs. K., aged 54. Passed the menopause three or four years ago, and has been in poor health ever since, suffering much from spinal irritation, and at times with severe epistaxis. When she first consulted me in the spring of 1881, she complained much of a persistent pain coming on soon after defecation. A near relative having cancer of the cervix uteri (since dead of it), my patient desired a thorough examination. This revealed a hyperinvoluted uterus in a healthy condition, except a slight lateral flexion. An anal fissure was found to account for the pain in that region. The iodoform ointment was ordered, and succeeded as before in relieving the pain promptly, with an ultimate cure. A year and a half later, coincidently with a stubborn attack of chronic endometritis, there was a slight return of the anal fissure, which yielded as before, only more speedily, and long before the uterine catarrh was wholly cured.

Case V.—Mrs. L., a young married lady, a nullipara, who was spending the summer in Atlantic City, suffered with acute and long-lasting pain after each act of defecation, which she attributed, as is usual, to hemorrhoids. I examined, and found two anal fissures. While my finger was exploring the rectum it detected a marked retroflexion of the uterus. Believing this flexion to have been the predisposing cause of the fissures, I advised that it should be immediately corrected, meanwhile, however, endeavoring to heal the latter by ointments. The lady preferred not to risk the iodoform smell, even in a modified form, while residing in a hotel. I ordered, therefore, the following, which is so highly recommended by Allingham:

℞.—Hydrarg. subchlor., . . . gr. iv.
Pulv. opii, ... gr. ij.
Ext. belladonnæ, ... gr. ij.
Ung. sambuci, ... ʒj.—M.
Sig. To be applied frequently.

No laxative was needed in this case, since the patient's regular habit was to have one or sometimes two loose movements every morning.

There being fortunately no adhesions, the uterus was easily restored to its normal position by pressure with the fingers behind the fundus, while the patient occupied the knee-chest position. A Smith's Hodge pessary was then fitted. This was worn with perfect comfort and with the effect of curing a dull backache, which she had long endured without knowing its cause. The pain at the anus was somewhat alleviated by the ointment of calomel, etc., during the intermenstrual period, but becoming very severe again during menstruation, the iodoform ointment was resorted to. Whether, because an impure drug was furnished, or because of an idiosyncrasy, the lady suffered increased pain whenever this ointment was used, and therefore soon abandoned it. Some years before in prescribing iodoform for an old leg ulcer, a like difficulty

was encountered. The powder in that case caused severe smarting pain, and upon being examined seemed to have been adulterated with yellow mustard! The lady insisted now upon an operation. Gas having been administered by a dentist, I dilated the sphincter and snipped off with curved scissors an old shrunken external hemorrhoid. The result was entirely successful. The fissures speedily healed and have not been felt at all since, even during menstruation. At the end of a month a careful examination showed no trace of them. The patient still wears the pessary (four months after the reposition) and suffers no inconvenience. Once, when I removed it to see if she could do without it, the uterus resumed its old malposition, with the result of bringing back the former sacral pain. For the morning diarrhœa, which was accompanied by a coated tongue, and was probably due to faulty hepatic function, I prescribed minute doses of hydrarg. chlor. mit. and podophyllin in powders with sugar of milk. These were continued several weeks, with the result of procuring nearly natural stools. The cure was completed with small doses of argentum nitrate, and the patient, when I last saw her, reported herself in perfect health.

It is noteworthy that of these five cases of anal fissure, four occurred in women, all of whom had some uterine difficulty, except one who just passed through parturition—a process very apt to irritate the rectum. Some of the gynecologists maintain that uterine affections are often the consequence of rectal disease; while the rectal specialists insist, on the other hand, that uterine displacements are a frequent cause of disorders of the rectum and anus. Probably both are right.

In treating anal fissures by iodoform, or by any other means, indeed, it is important to use just sufficient of the mildest laxatives to produce one soft stool daily. Anything approaching purgation will be likely to aggravate the congestion and prevent a cure.

In the prescription herein recommended, the iodoform is, no doubt, the most efficient agent, since it is found highly curative in ulcerations everywhere, of various kinds; but the balsam of Peru, probably, adds decidedly to the healing powers of the salve, besides lessening the pungency of its odor. The iodoform acts not only as an alterative and stimulant, but is also a powerful local anæsthetic. Prof. Lyman, in his *Artificial Anæsthesia and Anæsthetics*, mentions that, "introduced into the rectum, it may render the anus quite insensible to the process of defecation." A drug with such powers ought, *a priori*, to be useful in fissure, and experience proves that it is.

A CASE OF ACCUMULATION OF GALL-STONES IN THE GALL-BLADDER AND CYSTIC DUCT,

RESULTING IN CLOSURE OF THE DUCTS, AND DEATH BY ASTHENIA.

By C. D. HILL, M.D.,
OF BETHEL, MAINE.

A. B., age 62, clergyman, of full habit, somewhat corpulent, consulted me September 23d, complaining of vague dyspeptic symptoms, such as gaseous eructations from the stomach, with a sensation of burning, heaviness, and occasional slight pains, referred to this region. The general uneasiness increased by lying down. Coated tongue; bowels constipated; stools lighter in color than normal; good deal of gas passed per rectum. Appetite good; pulse and temperature normal. Had lost considerable flesh and strength. Gave history of "not feeling well" since an attack of colic some time the previous spring. Had had a number of such attacks, distributed over a period of years; called, by quite a number of the various physicians who had attended him, "bilious colic." None of them had, to his knowledge, expressed any opinion as to the cause. Feces never had been examined for gall-stones. Had led a somewhat sedentary life.

Physical examination disclosed considerable tenderness over gall-bladder, with an indefinite feeling of enlargement; but owing to the amount of adipose tissue I was not satisfied in regard to this. Pressure produced a feeling of "sickness," which he could not describe or locate, but which was much intensified later in the disease. The area of hepatic dulness was not increased, except over gall-bladder.

The symptoms, with history, led me to strongly suspect the presence of gall-stones, with gradual closure of the common duct from the resulting inflammatory thickening. With this in view, I applied several blisters over seat of enlargement. Following these, I prescribed nitro-muriatic acid internally, and the acid pack externally, sulphate of quinine as a tonic, excluding fatty articles of food from the diet, regulating the bowels by laxatives.

Under the above plan a considerable degree of improvement took place; but he soon began to complain of the "sickness," which became a distressing symptom, at times resisting everything but opiates for its relief. It seemed to be caused by the accumulation of gas in the stomach or bowels, as it would abate for a time after the passage of gas.

In the latter part of October, the patient's strength in the mean time having gradually failed, he ceased to attend to his pastoral duties, and was confined to the house. Feces had been growing lighter and lighter in color, until, about November 1st, he became suddenly intensely jaundiced, with entire absence of bile from the stools. Blisters were again applied. Phosphate of sodium and sulphate of manganese substituted for the acid for a time. Attacks of the "sickness" became more frequent, and he was soon obliged to keep his bed. His appetite, which up to this time had been very good, began to fail. Progressive emaciation so facilitated examination that when the lungs were fully inflated a hard prominence could be distinctly felt in the situation of the gall-bladder. I no longer felt much doubt in regard to the diagnosis or probable prognosis.

In the latter part of November the patient was seen in consultation by Dr. I. T. Dana, of Portland, who fully endorsed my opinion.

With a faint hope that suppuration might release the supposed accumulation, poultices were applied.

A few days before death much tenderness on pressure was developed over gall-bladder and adjacent parts.

For several days previous to death patient could not be induced to take anything but a small quantity of brandy, with the morphia which was given to relieve the distress or "sickness."

There was no nausea or vomiting developed throughout the whole course of the disease.

Patient died December 9th, life seemingly terminated by asthenia, as the bile had been freely eliminated by the kidneys and skin, and his mind was perfectly clear to the last.

The autopsy showed much thickening of parts adjacent to the gall-bladder, which was nearly covered in by a mass of chronic inflammatory exudate, binding it firmly to the liver, duodenum, etc. The bladder contained a small quantity of thin, purulent fluid, and upwards of three hundred gall-stones, very dense in structure, weighing in the aggregate two hundred and thirty-five grains, the largest eight and a half grains. The coats of the bladder were much thickened, and several of the larger stones had become partially sacculated. The cystic duct could be traced in the firm exudate in which it was involved only by the impaction of several small stones along its course; this exudation having the appearance of old scar-tissue. The common duct was obliterated for, perhaps, two-thirds of its extent, and the hepatic for a little way above the junction; appearances indicating that this occlusion was of much more recent date than that of the cystic—the gall-bladder having been doubtless out of use for an indefinite length of time, the bile in the mean time having passed from the liver directly into the duodenum through the hepatic and common ducts. It seems remarkable that the stones along the cystic duct should not have given rise to more disturbance, as he had experienced no pain of any consequence since the attack of colic in the spring, which, however, was of several days' duration I believe. There was some congestion, but no organic disease of the liver.

DISLOCATION OF THE HEAD OF THE FIBULA FORWARD AND OUTWARD.

By IRA B. READ, M.D.,
of New York.

The infrequency of this accident is, perhaps, sufficient excuse for desiring it put on record.

On Sunday, December 26th, I was called to see J. Q., who, the messenger said, had hurt his leg, and the bone was "sticking out." I found him with the left leg extended, and in great pain. He said, that while shoeing a horse the animal had suddenly swerved around, carrying him with him, in such a manner as to double his leg under him. He felt a severe pain and a snap, as if something had given way.

On examination I found the head of the fibula projecting forward and outward in an unmistakable manner. I endeavored to reduce the dislocation, without success, and then called in assistance, and gave the patient chloroform. During the inhalation he became very refractory, and it required several men, who were standing around, to hold him. He soon became perfectly quiet, and we were about to reduce the dislocation, when we discovered that his struggles, together with the firm, and by no means gentle, pressure of those holding him, had reduced it for us, and the contour of the knee was perfect. There was considerable soreness. The knee was bandaged, and a compress with a short splint bound over the affected part, and the patient kept quiet for about two weeks. He is now well.

I find that Hamilton mentions but three cases collected by Malgaigne, and one by J. E. Hawley, of Ithaca, N. Y. Holmes says: "Dislocations of the head of the fibula have been occasionally met with, both from relaxation of the ligaments which connect it with the tibia, and from rupture of the same by violence." He mentions an extraordinary case reported by Boyer. Erichsen says: "The head of the fibula has occasionally, though very rarely, been displaced by the application of direct violence to it." He mentions Boyer's case, also one by Sanson, and one of his own.

This gives seven cases which I have gathered from the authorities at hand, my own making the eighth. It is needless to enter into the pathological or anatomical relations here. The case I have related was unmistakable, and that the reduction was accomplished so easily was a matter of congratulation, rather than of regret or chagrin, that my own hands had not effected it.

HOSPITAL NOTES.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

(Service of John Ashhurst, Jr., M.D.)

FOUR CASES OF DOUBLE AMPUTATION.

(Reported by George Woodruff Johnson, M.D., Resident Surgeon).

Case I.—T. W., aged 48 years, a brakeman, fell from the top and was run over by the wheels of a freight car, on the 4th of November. When first seen, although hemorrhage had been profuse, the patient was sitting up in the cab of an engine in which he had been brought from the seat of the accident, in apparently a very comfortable condition. The right arm and left foot were terribly crushed and mangled, and the hemorrhage still continuing, an Esmarch tube was applied as low down as possible on both the upper and lower limb. He was immediately brought to the hospital, and, his general condition being most favorable, Prof. Ashhurst proceeded to amputate, scarcely one hour after the reception of the injuries. The patient being etherized, an amputation, after the method of Sédillot, was performed at the middle third of the leg, the arteries being tied with the ordinary silk ligature, and the stump dressed with pure laudanum. A circular amputation at the upper quarter of the forearm was next done, the wound being brought together in such a way as to allow of the most perfect drainage, and the stump dressed in the same way as that of the

leg. The patient had some vomiting while under the anæsthetic, but reacted rapidly and well. Five grains of carbonate of ammonium were directed to be given every two hours, and the diet to consist exclusively of milk. On the day after the operation, the patient complained of nothing so much as of not getting enough to eat. On the 6th, two days after the operation, the stumps were dressed with dilute alcohol, the carbonate of ammonium was stopped, and four ounces of whiskey (to be taken in the form of a punch), and eight grains of quinine daily, were prescribed. On the 8th, the patient's bowels were opened by an injection of warm water and soap-suds. Tongue somewhat coated; complains of no pain or inconvenience; sleeps well. On the 9th, quantity of whiskey increased to six ounces daily. On 13th, all ligatures, and all but two stitches away from leg; union very good, as is also general condition of patient; bowels opened regularly. On 15th, whiskey diminished to four ounces, food increased in variety. On 16th, remaining stitches in leg removed, and flaps supported by strips of adhesive plaster; stitches also removed in arm. 18th, all ligatures out of arm; leg stump dressed with zinc ointment, spread upon patent lint, and covered by the original alcohol dressing; arm dressed with zinc alone. 21st, leg dressed with zinc alone; union both in arm and leg excellent, a major part of each stump having united by adhesion. The general condition of the patient is now, as it has been all along, most excellent; in fact, if we leave aside the existence of a small bed-sore situated over the sacrum, the case has progressed without a single unfavorable symptom or complication.

CASE II.—Benjamin S., aged 28 years, a machinist, fell under the cars at Tacony on November 7th, and sustained severe crushes of left arm and left foot. He was admitted about noon, in a condition of profound shock. Hot-water cans were placed around him, he was warmly covered, and five grains of carbonate of ammonium were given twice within the hour, accompanied the last time by about ten drops of deodorized laudanum, the injured man being very restless, and complaining a great deal of pain, At one o'clock his condition appeared to be satisfactory enough to warrant operative interference. The leg was removed at its lower third, by the modified circular method, the oval skin flaps being approximated in an antero-posterior direction; while in the arm, at its upper third, the simple circular method was employed, an external slit, however, being made, to allow the ready reflexion of the skin-cuff. The patient's general condition during the operation, which was performed as speedily as was consistent with propriety, was very poor, and it was necessary to occasionally administer ether subcutaneously, as a stimulant. The stumps were dressed in the same way as has been already mentioned, and five grains of carbonate of ammonium every hour, with a half ounce of whiskey every two hours, were prescribed.

On the 8th, the day after the operation, the pulse was 140; respiration 28; skin cool and leaky; tongue coated with whitish fur; appetite ravenous (milk the only food allowed), and thirst annoying. The ammonia was given every two hours, with the whiskey at the same interval, and also two grains of quinine and ten drops of tincture of digitalis four times in the twenty-four hours.

9th.—Patient very drowsy, and complains of headache. Bowels freely opened. Stumps looking well; dressed with alcohol.

10th.—Pulse 120, and of good volume. Blue-mass, in one-quarter grain doses, given with quinine four times daily. Vomited twice last night. Two passages from bowels, perfectly white, inoffensive.

11th.—The ammonia stopped. Tongue dry. Whiskey increased to eight ounces. General condition improved.

13th.—Stumps look well; very little suppuration. Patient allowed beef-tea in addition to milk.

15th.—Blue-mass stopped. Zinc and alcohol both used in dressing arm.

16th.—All stitches out of arm and leg. Zinc alone used in arm. Flaps well united; supported by strips. Digitalis stopped. Food increased in quantity and variety. Pulse quiet; tongue clear, but still dry. In the evening the position of the patient's bed was changed, and there resulted some headache, with quick, irritable pulse, and some restlessness.

20th.—All ligatures away from arm.

22d.—All ligatures away from leg. Whiskey reduced to six ounces. General condition of patient excellent.

24th.—Whiskey reduced to four ounces.

CASE III.—John G., aged 45 years, a laborer, was struck and run over by a locomotive engine, sustaining a severe crush of the right forearm and left leg. He was admitted to the hospital a short time after the reception of the injury, on the 8th of December. The patient complained of great pain in the shattered limbs, but was so little overcome by shock that, amputation being necessary, it was resorted to at once. The forearm was removed at its lower fourth by the ordinary circular operation, with an external slit, and the leg at its lower-third by the modified circular with lateral flap. The patient stood the operation remarkably well. By the 16th all stitches had been removed from both leg and arm; the stumps were doing remarkably well. At the time of the present writing the patient is out of immediate danger, and, unless some unforeseen complication should arise, will undoubtedly get well. No stimulants, except carbonate of ammonium immediately after the operation, have been prescribed, and quinine, combined at first with a little blue-mass, is all that the patient has received in the way of medicinal treatment.

The three cases of double amputation just recorded were, as will be seen, admitted within a short time of each other, and were under treatment in this hospital at the same time.

CASE IV.—On the 4th of September a man, E. S., aged 21, was admitted to the surgical wards, a Chopart of the right foot and an anterior and posterior skin flap amputation of the left leg, having been that day performed by a surgeon in one of the neighboring Pennsylvania towns. From the notes taken by my predecessor, Dr. George E. de Schweinitz, under whose care the patient was until October 1st, I find that the case progressed most favorably, nothing unforeseen occurring to mar the rapidity of the cure. The patient was discharged on November 2d; the result being in all respects excellent.

MEDICAL PROGRESS.

THE VALUE OF KOCH'S RESEARCHES IN TUBERCULOSIS.—DR. HERON believes that through Koch's researches we have now a method of investigating lung diseases which, standing alone and unsupported by any other method of examination, throws a special light upon a patient's condition. Speaking from his own experience, bacilli of tubercle are not always present in the sputa of patients whose physical condition would lead any one who knows something of Dr. Koch's work to expect to find them there. It is also a matter within his own experience, and it has happened to him more than once, to search the sputa for bacilli of tubercle and to fail to find them early in the history of a case of consumption. In the same case, within

one or two months, he has found bacilli in the sputum, and in one instance in enormous numbers.

His experience also inclines him to expect to find it established very shortly, that in the prognosis of phthisis we must look to this method of investigating the sputum for valuable information. He thinks it will be established that, given persistence of a large number of bacilli of tubercle in the sputum early in the history of a case, and that case will run a short course and end in death. On the other hand, he thinks it will also be established that, given few bacilli of tubercle in the sputum of a consumptive, and given also, that that condition of fewness of bacilli in the sputum characterizes the case for some weeks, then that case will probably run a long course.—*Glasgow Medical Journal*, February, 1883.

Cholesterine in the Brain.—Prof. Beneke has recently published a work on the *rôle* of cholesterine in the brain. In the brain of a child, fifteen years of age, who died of phthisis, he found it present in the proportion of 2.34 per cent. of brain substance. It was also found in the brain of a young woman who died of puerperal fever, in the proportion of 2.13. According to the author, cholesterine plays an important part in the constitution of the protoplasmic matter from which the tissues are formed.—*Revue Scientifique*, February 10, 1883.

Trephining for Intra-cranial Abscess.—Dr. Kilgariff exhibited a patient before the Surgical Section of the Academy of Medicine, in Ireland, on whom he had performed the operation of trephining on account of an abscess resulting from a fall in the hunting field. The patient was unconscious for two hours after the accident. At the end of a fortnight he was removed to Dublin, suffering much from pain over the upper part of the occipital bone on the right side, and also much gastric irritability and general debility. Any motion, such as driving, intensified the pain, and caused nausea. On examination a shallow depression, the size of a florin, was found, bound by a well-defined margin, at the situation where he complained of the pain. The diagnosis of fracture, with the subsequent formation of an abscess within the cranium at the seat of the lesion, was made. An exploratory incision was made down to the bone, and a small purulent collection was opened into. Subsequently the operation of trephining was undertaken; and on exploring the bone a small circular opening through the skull, about two lines in diameter, was discovered. Through this opening, situated on the upper part of the occipital bone, some purulent matter oozed. A circular piece of bone was then removed with the trephine to provide free exit for the pus. An abscess cavity, from which almost half an ounce of pus welled up, was opened into. The inner surface of the piece of bone removed was deeply eroded. The cavity of the abscess was washed out with a weak solution of carbolic acid. Subsequently the patient experienced an attack of erysipelas of the head and neck, from which, however, he recovered, and nothing further occurred to interrupt the process of complete recovery of the patient.—*Dublin Journal of Medical Science*, January, 1883.

The Treatment of Hypertrophied Palatal Tonsils.—Dr. D. N. Rankin believes that after a general and local therapeutic treatment judiciously and unsuccessfully pursued, the following circumstances should be considered before excision be attempted.

1. Those in which an operation is contra-indicated: he has in his own experience observed cases (and they were not a few) where excision was contra-indicated. The operation should not be made when the glands are inflamed, especially if the patient is of a hemorrhagic diathesis, unless suffocation be threatened.

2. Those where an operation is justifiable and advisable: When from the great size of the glands the patient is in danger of immediate suffocation, in whatever condition they may be found; after all inflammation has been removed; when deafness, impaired speech, or frequent attacks of tonsillitis are produced, the operation should undoubtedly be made, and fully one-half of the tonsil be removed, as in his opinion the removal of less does not insure a good result. But one tonsil should be operated on at the same sitting.

3. The most suitable age at which the operation should be done: Experience has taught him that where there are no alarming symptoms present, demanding the operation earlier, between the fifth and eighth years is the time the operation can be done most satisfactorily.—*Archives of Laryngology*, January, 1883.

Gastro-enterostomy.—Dr. Fischer, of Strasburg, describes, in the *Deutsche Zeitschrift für Chirurgie*, a remarkable abdominal operation. In 1881 Freund removed a fibroid uterus from a woman, aged 30. Last May this unfortunate patient, who appears to have been predestined to be a victim to abdominal disease, was found, by Dr. Fischer, to be suffering, according to his diagnosis, from carcinoma of the pylorus. Lücke determined to attempt resection of that part of the alimentary canal. From May 13, 1882, to May 25th, the stomach was washed out, every day, and on the 25th, after an enema had also been administered, the operation was commenced, without spray. The parts were exposed by a free incision, but resection was found to be impracticable, owing to extensive adhesions between the pylorus and the neighboring structures, especially the pancreas. The pylorus was therefore laid open and the aperture united to the abdominal wound, as in a gastrostomy. The opening left in the wound was dressed with iodoform, and covered in with thymol-gauze. After the operation, the patient did well, the temperature rose but little above normal, and she was discharged in thirty-seven days. Since then she has enjoyed very fair health, being free from attacks of vomiting, and can easily digest light, nutritious food.—*British Medical Journal*, February 3, 1883.

The Parasite of Yellow Fever.—According to the *Gazette Medicale de Mexico* Dr. Carmona del Valla claims to have discovered the parasite to which yellow fever is due, and which he calls *peronospera lutea*. He has detected it in all the secretions, in the blood, and in the contents of blisters of persons suffering from yellow fever, and also in the vomited matter large amounts of black mycelium are to be met with, and he considers that the color of black vomit is due to the presence of this mycelium, and not to extravasated blood. He has observed the development of granules in the urine, which ultimately form the spores of this mycelium, and when this urine is injected under the skin of rabbits it causes intense fever, during which similar spores may be met with in the urine, and the animal is subsequently protected from yellow fever. Dr. Carmona made an injection of this parasite on himself to demonstrate its harmlessness.—*Rev. de Thérapeutique*, February 1, 1883.

Nephrectomy.—At the meeting of the Surgical Section of the Academy of Medicine, in Ireland, Mr. Stokes, on behalf of Mr. Francis J. O'Reilly, Surgeon to the Trim Union Infirmary, exhibited a right kidney which Mr. O'Reilly removed by lumbar section from a patient, aged twenty-six, in that institution, who suffered from right kidney symptoms and pus in her urine. He read Mr. O'Reilly's communication on the

subject, which disclosed that the girl was never free from a desire to pass water, so that her sufferings were of a truly agonizing character. The quantity of urine passed daily was fairly normal, and the specific gravity ranged from 1015 to 1020. A favorable opinion was thus entertained of the capabilities of the left organ to discharge the increased functions with which it was about to be taxed. The operation was by the vertical lumbar, or post-peritoneal method, and was performed antiseptically. The vessels and ureter were secured by a whipcord ligature. The external wound was closed with interrupted sutures, and antiseptic dressings were applied. The patient suffered from vomiting during the late stages of the operation. The gland weighed eight ounces; and an abscess cavity at its superior extremity contained about two ounces of pus. The vomiting and depression which manifested themselves during the operation continued, and the girl sank, and died forty hours after the operation. About an ounce of urine was drawn off with the catheter previous to death, and did not contain a trace of pus. The kidney was a specimen of primary tubercular disease. A *post-mortem* examination was not obtained, but the wound was investigated and found free from blood clot, and perfectly aseptic.—*Dublin Journal of Medical Science*, January, 1883.

A NEW METHOD OF RESECTION IN OLD CASES OF PES VARUS.—The method which DR. RYDYGIER, of Kulm, proposes in such cases is as follows: A curved incision is made through the skin two centimetres in front of the external malleolus, in order to avoid opening the joint, the convexity being downwards, and prolonged over the outer side of the dorsum pedis to the centre of the cuboid bone. Through this incision, which reaches to the bone, the necessary resection can be readily made with a chisel without injuring any important structure. In the first place the neck of the astragalus is chiselled through obliquely from the outside inwards, and in the same direction further downwards, the anterior process of the calcaneum, so that a perpendicular wedge, with the base outward and above, is resected. By this means a great part of the deformity is corrected. To remedy the obstruction to the adduction and supination of the foot caused by the anterior process of the calcaneum, he resects a horizontal wedge-shaped piece, with the base outwards, from the upper surface of the anterior process of the calcaneum. A drainage-tube is inserted, the wound closed, and Lister's dressing applied, and a plaster bandage to keep the foot immovable. When a pes equinus is present, the tendo Achillis should be first divided.—*Berliner klin. Wochenschrift*, Feb. 5, 1883.

NEW METHOD OF DETERMINING THE RELATION BETWEEN CONVERGENCE AND ACCOMMODATION.—DR. MADDOX has devised a new instrument for testing the relation between convergence and accommodation. It consists of a small wooden box forming a dark chamber, into which both eyes are directed; a small aperture in the far side of the box affords a binocular fixation point. A small shutter is moved so as to intervene between the fixation point and one eye. This eye being then in darkness, assumes its position of equilibrium. The novelty and ingenuity of the instrument lies in the mode by which the position of the occluded eye is ascertained. In the far side of the box is a sliding strip of brass (one for each eye), in which is a minute aperture giving a point of light; this is moved until the point of light falls upon the optic disk and thus becomes invisible; the direction of the optic axis can be read off from degrees marked upon the slide.—*Ophthal. Rev.*, February, 1883.

PORRO'S OPERATION IN ITALY.—DR. BIANCHI reports (*Gazzetta degli Ospitali*, January 24, 1883) a case in which Dr. Barsotti performed Porro's operation, at Lucca, on December 28, 1882. The patient was rickety, and suffered from pneumonia and mitral insufficiency. The deformity of the pelvis was so great as to render any process of embryotomy impossible. The operation for the removal of the uterus and ovaries presented no unusual difficulty, but the mother died from exhaustion the following day. The child (male) survived, and was in good health at the end of a fortnight. According to Dr. Negri, Porro's operation was performed in Italy thirty-eight times from May, 1876, to May, 1882; fourteen of the women recovered and twenty-four died. It would also be interesting to know how many of the children survived.—*Lancet*, February 3, 1883.

CALCIFICATION OF THE KIDNEYS IN SUBACUTE POISONING WITH CORROSIVE SUBLIMATE.—MM. PREVOST and FRUTIGER have determined, by a long series of experiments made on various species of animals, that the continued administration of corrosive sublimate leads to a deposit of calcareous salts in the cortical substance of the kidney, commencing in the narrow tubules of the cortex; implicating then the tubuli contorti, and occasionally the entire medullary substance, giving the kidney the appearance of petrifaction. The administration of doses sufficiently large to produce death in about four days, produces a more marked deposit than when small doses are repeatedly administered. Proportionately with the deposit of calcareous matter in the kidney, there occurs a decalcification of the bones, the loss often reaching ten per cent. of the normal amount of salts present in bone.—*Gazette Méd. de Paris*, February 10, 1883.

TYPHOID FEVER COMPLICATED BY BILIARY CALCULI.—MR. ROBERT S. ARCHER reports two fatal cases of enteric fever, complicated by biliary calculi, which show that a fatal result may be induced by the *direct* mechanical irritation of a calculus (even a very small one) causing hemorrhage; that death may arise from the direct action of a stone on the floor of an ulcer, causing perforation; that serious hemorrhage may result from *reflex* irritation set up by calculi confined in the gall-bladder; that this hemorrhage may kill directly by its large quantity; that it may kill indirectly, by causing exhaustion and inability to withstand a prolonged and weakening acute affection; that in the course of enteric fever no sign or symptom may present itself whereby it is possible to diagnose the presence of biliary calculi.—*Liverpool Med.-Chirurg. Journ.*, January, 1883.

THE PARASITES IN PORK.—From the examination of one thousand hogs in the slaughter-houses of Montreal, Dr. WM. OSLER draws the following conclusions:

1. The investigation shows that the hogs slaughtered for our markets present parasites in numbers sufficient to necessitate a more thorough inspection than is at present carried out.

2. As regards *Trichina spiralis*, which was found in the proportion of 1 to 250, we are of opinion that, considering the extreme rarity of cases of trichinosis, and the difficulties attendant upon a systematic inspection, a compulsory microscopic examination of the flesh of every hog killed is not at present called for.

3. In the case of "measles," the liver should be carefully examined, and if present in it, the flesh of the animal should receive the special attention of the inspector; if only in the liver, the entire carcass need not be confiscated.

4. Echinococcus cysts in the liver render that organ unfit for food, but in other parts, unless very numerous

and disorganizing, they may be cut out, and the carcass remain marketable.

5. The public should be made aware of the possible dangers of eating, in any form, raw or partially cooked meat. The best safeguard against parasitic affections is not so much inspection of the flesh, unless, indeed, this is minutely carried out, as careful attention to culinary details.

6. To reduce the number of infested hogs, greater attention should be paid to their hygienic surroundings, particularly in the matter of feeding. The danger is not during the period when the animals are penned and fed on grain, etc., but when they are allowed to roam at large and feed indiscriminately.

Paraldehyde: a New Hypnotic.—The actions of this drug were first studied by Dr. Cervello, of Palermo; and his experiments were made in the laboratory of Experimental Pharmacology at Strasburg, under the direction of Schmiedeberg. Professor Morselli, of the Royal Asylum of Turin, has, in conjunction with Dr. Bergesis, the assistant medical officer, made an extensive series of observations with it. Its chemical composition is $C_6H_{12}O_3$; and it is a polymeric form of aldehyde. In physiological action it strongly resembles chloral. A dose of three grammes procures quiet and refreshing sleep for from four to seven hours. It differs from chloral in its action on the circulatory system, strengthening the heart's action, while diminishing its frequency. It has also a well-marked action on the kidneys; greatly increasing the flow of urine. The skin is not at all affected. The drug does not give rise to digestive disturbances, to headache, or to any other unpleasant symptom. Up to the present, Professor Morselli has used paraldehyde about three hundred and fifty times. He has found it a valuable remedy in mania, melancholia, and other nervous affections, as well as in the sleeplessness that accompanies acute bronchial catarrh, lobar pneumonia, and heart diseases. He believes that it will to a large extent take the place of chloral.—*British Medical Journal*, February 3, 1883.

Treatment of Exophthalmic Goitre by Subcutaneous Injections of Duboisia.—M. Desnos reports three cases of exophthalmic goitre treated by a daily subcutaneous injection of from one-half to one milligramme of neutral sulphate of duboisia. In all three cases the improvement was marked: there was diminution in the projection of the eye, and in palpitation; improvement of the general health, and reduction in the pulsation and murmur in the thyroid gland. When the treatment was discontinued the improvement disappeared. Further observations are necessary to determine whether a permanent cure may be produced by means of this drug. In two cases there were slight symptoms of the physiological action of the drug.—*L'Abeille Méd.*, Feb. 5, 1883.

The Solar Plexus in Typhoid Fever.—Dr. Leven (*Gaz. des Hôp.*, January 30, 1883), of the Rothschild Hospital, draws attention to the fact that, among the numerous cases of typhoid which he saw during the late epidemic, there were very few unattended with abdominal symptoms, and he believes that these are frequently caused not so much by the disease itself as by the faulty practice of administering purgatives which excite the nervous system of the abdomen; and that the pain in the iliac fossa, which has been regarded as characteristic of the disease, is confounded with a hyperæsthetic condition of the abdominal parietes induced by the irritation of the right nervous ganglion produced by the same treatment. When diarrhœa is produced by purgatives given during the febrile condition, the nervous ganglion of the great sympathetic, placed at four centimetres distance from the umbilicus, becomes irritated, and tenderness is felt on pressure there. Whenever diarrhœa exists it should be arrested by means of bismuth, as its only effect is to aggravate the adynamia and exhaust the strength.—*Medical Times and Gazette*, February 10, 1883.

Peculiar Characters of the Serous Contents of an Inguino-abdominal Tumor.—MM. J. Regnauld and Villejean detected in the fluid contents of an abdominal tumor, drawn off by aspiration, an albuminoid principle closely analogous to fibrine, with the exception of not being spontaneously coagulable. It was precipitated by the addition of water, and closely resembled fibrine in its general character, and existed in about five or six times the proportion in which fibrine is generally present in blood plasma. The fluid contained also, metalbumen, serin, and peptones, while globulin and mucin were absent.—*Arch. Gén. de Méd.*, February, 1883.

Abdominal Section for Puerperal Peritonitis.—In a recent number of the *Wratsch*, Dr. Molodenkoff, of Moscow, describes the case of a woman, aged 28, who was admitted into hospital ten days after delivery, for diarrhœa, fever, and swelling of the hypogastrium. Ten days later, the abdomen was much distended, and on exploratory puncture purulent fluid was obtained. On the next day, an incision was made along the linea alba, and a great quantity of pus emptied out of a circumscribed cavity formed between the abdominal wall and adherent coils of intestine. To facilitate thorough drainage, a second opening was made immediately above the symphysis; and after tubes were inserted into the wounds, the whole was covered in with antiseptic dressings. On the next day symptoms of carbolic poisoning appeared. Much pus escaped, great prostration set in, and the patient rapidly lost strength, dying on the fourth day after operation. At the necropsy, ten smaller circumscribed collections of pus were found between coils of intestine, inaccessible to the drainage tubes, as they had been arranged, besides the large cavity that had been effectually drained. The mucous membrane and peritoneal covering of the uterus and the ovaries were acutely inflamed. Dr. Molodenkoff concludes, from his personal experience in this case, that abdominal section and washing out of the peritoneum, with subsequent drainage, is not justifiable in cases of purulent peritonitis. Last year, Dr. A. Schmidt described, in the same Russian paper, a successful case of what he considered to be laparotomy and clearing out of an intraperitoneal collection of pus; but Molodenkoff believes that an abscess in the abdominal walls only was emptied, and that the peritoneal cavity was never opened. In the *Deutsche Medicinische Zeitung*, this point is disputed. There appears, according to that journal, to have been no doubt that Dr. Schmidt opened the peritoneal cavity; but, it is pointed out, this was a case of very chronic purulent peritonitis of half a year's duration, whilst Molodenkoff's patient was suffering from an acute puerperal complication. There can be no doubt as to which proceeding was the most justifiable.—*Brit. Med. Journ.*, February 10, 1883.

Porro's Operation.—Dr. Leopold Dejace has recently performed the first case of Porro's operation in France. He followed Müller's modification, with the exception that he amputated the uterus before extracting the fœtus. The result was successful, as regards both mother and child.—*Journ. de Méd. de Paris*, February 10, 1883.

FUNNEL-DRAINAGE IN ANASARCA.—This is a method of removing large quantities of fluid devised by DR. STRAUB, of Tübingen. It is simpler than Southey's, and affords more relief in equal time. The apparatus consists of an ordinary glass filtering funnel, of about two inches diameter, with attached to the end of it an India-rubber tube, one-eighth inch in diameter, and long enough to reach to the floor. If the apparatus is filled with water, and the mouth of the funnel firmly applied to the skin of a patient lying in bed, while the end of the tube is immersed in a vessel on the floor containing a little water, it will be found to adhere quickly and act as a sucker: and when the funnel is applied over several small incisions or punctures in a case of œdema, the tube acting as a siphon will keep up a continuous drainage of serum into the vessel. The force of the suction, can, of course, be regulated by altering the level of the vessel, and the flow of fluid can be watched by a piece of glass tubing let into the India-rubber tube. The apparatus, if protected by a small cage or cradle, can be left on for any length of time, and is not displaced by movements of the patient if ordinary care is taken. Enormous quantities of serum have been drained off in this way. In one case of chronic Bright's disease there were drawn off in two and a quarter hours, over 78 ounces (2,270 ccm.); in seven hours, over 96 ounces; and in twenty-four hours, 278 ounces (8,050 ccm.); and in another case of extreme general dropsy from Bright's disease, nearly 43 pints (24,800 ccm.) were removed in seventy-nine hours.—*Glasgow Medical Journal*, February, 1883.

TRANSITORY AMAUROSIS FROM CARBOLIC ACID POISONING.—A. NIEDEN reports a case in which amaurosis, lasting for twenty hours and then gradually entirely disappearing, followed the washing out of a pleural sac for empyema with about 100 cc. of a three per cent. carbolic acid solution. Immediate collapse followed the injection, soon followed by a condition of great weakness, with dyspnœa, nausea, and absolute blindness. An ophthalmoscopic examination revealed nothing abnormal, though the pupils were widely dilated.—*Centralblatt f. Chirurg.*, February 10, 1883.

EXTIRPATION OF THE LARYNX.—At the meeting of the Calcutta Medical Society, held December 13th, DR. MCLEOD exhibited a larynx which he had recently extirpated. The patient, a middle-aged man, tall, sallow, and thin, had suffered from aphonia for a year, and about three months before admission a growth had made its appearance over the right side of the larynx. It presented the appearance of a raised excrescence, overhanging the surrounding skin at the circumference. The skin was infiltrated at its base, and the growth had evidently sprung from the interior of the larynx. It could be felt filling up the rima glottidis by the finger introduced through the mouth. Finding that it was still confined to the larynx, except so far as it had implicated the skin in front and to the right of it, and hoping that the whole mass could be extirpated without much serious risk to life, an operation was undertaken for that purpose. The thyroid body was carefully exposed, and found to be implicated on the right side. Its removal therefore became necessary. This added considerably to the difficulty and gravity of the operation, because division of the thyroid vessels was unavoidable. They were secured by ligature before division, and very little blood was lost. The larynx including the tumor was isolated as completely as possible before the trachea was divided, and its subsequent separation was accomplished by dissection with blunt-pointed scissors, from below upwards. Chloroform was given by mouth in the first instance, and then through the divided trachea. The patient had suffered a good deal from shock, but had made, on the whole, a satisfactory recovery. No irritation of the lungs of any consequence took place. Irritation of the lower bowel was caused by frequent injections, but that was overcome by the use of starch and laudanum. The patient could be made to whisper, by closing the external wound, and hopes were entertained that he could eventually be made to talk by means of an artificial larynx.—*Indian Medical Gazette*, Jan. 1, 1883.

THE THERAPEUTIC USES OF HOT WATER IN GYNECOLOGY.—In addition to the well known valuable properties possessed by hot-water injections in controlling uterine hemorrhage, RUNGE also recommends their use whenever a contracted condition of the uterus is indicated: thus he has obtained good results by this plan of treatment in acute retroflexion accompanied by hemorrhage. When, however, the bleeding is due to some pathological condition, such as fungoid endometritis, fibroma, etc., no permanent good result can be expected. He believes that the results obtained may be attributed with equal force to the mechanical, as to the thermal stimulation.—*Central. f. Gynäkol.*, February 10, 1883.

DIABETIC AND NEPHRITIC NEURALGIA.—BERGER has recently published notes of twenty-one cases of typical origin, of which twelve were of diabetic and nine of nephritic origin. The ischiatic nerve and its branches were affected in the majority of cases; the neuralgia tended to be symmetrical, was often associated with vaso-moter disturbances and resisted all plans of treatment not directed to the fundamental disease. The violence of the neuralgia was usually proportionate to the severity of the original disease; and is attributed by the author to an implication of the central nervous system.—*Centralblatt f. klin. Med.*, February 10, 1883.

CONVALLARIA MAIALIS.—DR. B. STILLER, in the *Wiener Med. Woch.*, adds his experience to the observations on convallaria maialis, which, it will be seen, is of different tenor from that of the Russians, who introduced it, and of M. Germain-Sée, who first made it prominent.

Seventeen persons were treated by Stiller, some for relapses, making a total of twenty-one cases, fifteen of whom were males; the ages varied from eleven to seventy years, and the diseases were four cases of mitral insufficiency with aortic regurgitation, one of pure mitral regurgitation, five of regurgitant and stenotic mitral disease, four of mitral stenosis, five of weak heart with dilated left ventricle, and, lastly, two cases of Graves' disease, altogether a motley group of cardiac diseases. Out of the twenty-one cases seventeen gave absolutely negative results with convallaria; there was not the least influence on the frequency or rhythm of the heart's action. Some of these cases proving intractable to convallaria were subsequently benefited by digitalis; two individuals experienced a certain degree of the diuretic effect of the new drug without any of the other vaunted phenomena, not even the dropsy being diminished; two patients underwent decided improvement in most of the cardiac symptoms during the use of the new medicine, but these cannot outweigh the large balance of negative results.

It will be remembered that the advocates of this drug claimed for it all the advantages of digitalis in regulating the frequency and rhythm of the heart beats, increasing the strength of the contractions, and raising the blood pressure, and without any of the dangers of the cumulative action of digitalis.—*Boston Med. and Surg. Journal*, February 22, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.

SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MARCH 3, 1883.

PHOSPHOROUS POISONING.

A CAREFULLY observed and well-narrated case of phosphorous poisoning is contained in a recent number of *The Practitioner* (London). There are several interesting points connected with this subject. Phosphorus is taking high rank as a material for self-destruction. Phosphorous paste, as a rat poison, and match heads, are procurable by all who choose to buy them. It is said that, at the present time, one hundred match heads, pulverized, is the favorite dose of those bent on suicide in Germany. Besides the use of these forms of phosphorus by the suicide, they are, now and then, taken by accident. One of the amusements of children is eating match heads. It is very desirable, therefore, to have some clear notions regarding the symptomatology and treatment of phosphorous poisoning.

In the case above referred to, the quantity of phosphorus which produced death was, according to Dr. Stevenson, the eminent toxicological expert of Guy's Hospital, about two grains. For three and a half days after the ingestion of this fatal dose, there were no symptoms except epigastric pain, and the initial symptoms of jaundice, consisting of some yellowness of the conjunctivæ. The breath had a sulphurous odor, afterwards garlickly, on the fifth day, and the body was distinctly jaundiced, the urine containing a quantity of bile pigment. At this time the urine had a specific gravity of 1030, was acid in reaction and contained some albumen; the pulse was 104, and the temperature 99.6°. Delirium and involuntary evacuations occurred on the eighth day after the poison was taken, and death ensued on the morning of the ninth day. Notwithstanding the pronounced stomach pain, there was no inflammation of the mucous membrane of the stomach discovered on *post-mortem* examination. There are several reasons for this departure from the usual condition. The phosphorus was taken in a form adapted to ready absorption, and there was no production of phosphoric acid, to the destructive action of which, the erosions of the mucous membrane and the perforations are properly attributable.

There was the usual fatty degeneration of the liver, the heart, and the vascular system. Hemorrhagic extravasations were, however, wanting. Notwithstanding this is a symptom of phosphorous poisoning much insisted on by the systematic writers, it was wanting in this case, as it has been absent in a large proportion of the recorded examples of this affection. Jaundice was a pronounced symptom, and this appeared when otherwise there were almost no symptoms of illness. There are many interesting questions connected with the jaundice of phosphorous poisoning. Is it hæmatogenetic or hæpatogenetic? By Dr. Legg, the author of an elaborate work on bilious diseases, recently issued, it is regarded as hepatogenetic jaundice—that is, jaundice of hepatic origin, and according to him, due to catarrh of the bile-ducts, a secondary result of the gastro-intestinal catarrh, set up by the phosphorus. This case does not lend support to this view. There was no apparent catarrhal process of the gastro-intestinal mucous membrane. The mode in which the jaundice developed affords strong presumptive proof of its hæmatogenetic origin—that is, due to the disorganization of the blood. The close correspondence between the blood pigment and the bile pigment, has long been recognized; when, therefore, any condition exists by reason of which the coloring matter of the blood is separated from its usual associations, the appearance known as *jaundice* becomes manifest. The destruction of the red-blood globules, caused by phosphorus, and the separation of its hæmatin, would, therefore, seem to be a sufficient explanation of the phosphorous jaundice. Such is the view taken by Harley in his recent work on the liver; but it would be wrong to omit mention of the fact, that the existence of hæmatogenetic jaundice is denied by some of the most eminent of our modern pathologists.

The treatment pursued in the case on which we have commented seems to us very inefficient. Turpentine was used, and alcoholic stimulants, to afford the necessary support of the vital powers, were freely administered. There are several points on which criticism is demanded. The form of turpentine which has proved effective in phosphorous poisoning is the acid French turpentine, or its congener, old turpentine long enough exposed to the

air to have absorbed oxygen as ozone. The author of the paper from which we have quoted *näively* says "turpentine has been given in many others [cases besides his own] but with no definite results." He apparently failed to realize the form of turpentine which has been proved to be effective. He administered "ten drops of the oil of turpentine three times a day, a milk diet with eggs." The medicine was begun four days after the poison had been taken —or after its absorption had fully occurred. The acid French turpentine or ozonized turpentine, is effective whilst the phosphorus is still present in the stomach, and by actual contact converts the poison into a spermaceti-like substance, which is harmless. To administer the antidote after the phosphorus has diffused into the blood and caused the dissolution of the red corpuscles is simply idle. The experience of Jürgensen has shown that transfusion is the proper remedy when this condition of the blood results from phosphorus. He reports several cases in which cures were effected by the timely use of transfusion. The mechanism is obvious. Fresh blood, in a condition to functionate, is supplied in place of the poisoned blood so far damaged as to be unable ever again to perform its proper office.

THE TREATMENT OF MANIA AND EPILEPSY BY BROMIDE OF ETHYL.

THE unfortunate experiences which have been encountered in the use of ethyl bromide as an anæsthetic agent, although ending its career as a general anæsthetic, have not prevented further experimental study. In the skilful hands of Prof. Chisolm, of Baltimore, it has been revived as a most useful anæsthetic for procuring very temporary insensibility. We have now, however, to call the attention of our readers to the successful employment of ethyl bromide as an agent for bromide medication in general—for the speedy and effective introduction of a bromide compound into the blood. It must be well known to our readers that ethyl iodide has been utilized, especially by Dr. Lawrence, of Boston, and Prof. G. See, as a remedy for diseases, especially of the respiratory organs, in which the iodides have been proved to be serviceable. With the same view, ethyl bromide has been employed to procure the curative results now obtained by the administration of the bromides by the usual channels. The first attempts to treat nervous affections by ethyl bromide were made by MM. Bourneville et d'Olier, in 1880 (*Bull. Gén. de Thérap.*, vol. 100, p. 435). These observations have been continued by Dr. ROUX, under the supervision of the physician to *Bicêtre*, and appear in a thesis for the doctorate, an abstract of which is to be found in the *Journal de Thérapeutique, de Gubler*, for January 25, 1883. Observations have been made on the effect of the ethyl bromide as used in the treatment of the access of the epileptic paroxysm, and of the subsequent state, or intermediate stage. The epileptics thus treated were mainly those for whom the bromide of potassium had been used ineffectively during several years.

The physiological effects obtained from the inhalation of ethyl bromide are thus described by Bourneville: Complete muscular resolution is exceptional, and the degree of insensibility varies in different subjects. The temperature, the secretions, and the general state are not modified; the pulse and the respiration are a little accelerated. It causes some trembling, variable in amount during the inhalation, but this does not persist afterward.

The therapeutical results, as given by Bourneville, and also confirmed in independent observations by Roux, are as follows: Attacks of hysteria are in general quickly arrested by inhalation of ethyl bromide. The epileptic paroxysm may sometimes be arrested by giving this remedy during the tetanic stage; usually the inhalation has no effect on the spasms. The regular, daily inhalation of ethyl bromide during a period of one or two months, notably diminishes the frequency of the epileptic attacks. Dr. Roux also reports that using this agent in two cases of mania, one was improved, and one cured.

It must not be overlooked that some untoward results have been caused by the inhalation of ethyl bromide, according to Dr. Roux. In two cases it seems to have caused paraplegia. To prevent this accident, the inhalation should be suspended for several days after every two weeks of its continuous administration.

Further observations are necessary. There seems to be much promise in this mode of administering the bromides, as well as the iodides. As the purpose of the stomachal administration of any drug is to procure its admission to the blood, the method of inhalation offers conspicuous advantages in respect to the readiness of diffusion.

THE TREATMENT OF EPILEPSY AS CONDUCTED AT SAINTE-ANNE.

THE asylum Sainte-Anne offers an enormous opportunity for the study of epilepsy. In a thesis for the doctorate, DR. G. BOVÉ, who had the privilege to act as *interne* for Prof. B. Ball, embodies the observations made under these advantageous circumstances. The basis of the treatment of epilepsy, in this institution, consists in the administration of the bromides of sodium and ammonium, with oxide of zinc and belladonna. The formula for the bromides is the following:

℞.—Ammonii Bromidi,
Sodii Bromidi, . . . āā 160 grains.
Aquæ, ... ℥j.—M.

This is administered by teaspoonfuls in a cup of valerian tea. At the beginning of the treatment, four teaspoonfuls of the solution are prescribed daily, and the quantity is gradually increased up to eight or ten teaspoonfuls, if the amount first given proves to be insufficient.

At the same time a pill of zinc oxide and extract of belladonna is given, containing about one-half a grain of each ingredient. Two of the pills are administered every day, but, in obstinate cases, four may be given.

In cases of epilepsy, characterized by hyperæmia of the intra-cranial circulation, Prof. Ball uses revulsives behind the ears and to the nape of the neck, and prescribes some purgative pills every ten days. When the stomach is feeble, bitter tonics and pepsin are administered.

Dr. Boyé compares this plan of treating epilepsy, with that in which bromide of potassium is the principal remedy. The large field for comparative observations under his management at Sainte-Anne, gives peculiar value to his results. His conclusions are, that the bromides of sodium and ammonium have an immediate effect on the epileptic seizures; that they are much better borne than the potassium bromide, and that no disorder of the digestive organs occurs, except the dose be very large.

MEDICAL MATTERS IN CONGRESS.

In the debate upon the Army Appropriation Bill in the Senate, the amendment proposed by Mr. Logan to reduce the usual appropriation of $10,000 for the Army Medical Museum and Library to $5,000 was stricken out, and on motion of Senator Conger $7,000 was allowed for the Library, and $3,000 for the Museum.

The debate showed that few of the Honorable Senators knew anything definite about the Library or Museum, although we were glad to see that there was a general impression that they were valuable and useful. A letter from Dr. Billings to the Surgeon-General was read, in which, among other things, it was stated that "the demands upon the Library for books and information are steadily increasing, and there is not a week during which some books are asked for which it does not possess. During the past year, under the regulations which permit of the loan of books to other responsible libraries, books have been loaned to Boston, New York, Philadelphia, Baltimore, Chicago, Cincinnati, St. Louis, and other places for use by physicians in those places."

Upon this Senator Logan commented as follows: "That is not the way for the Government money to be used, buying books to be distributed around over the country for the use of other people. If they want them, let them go to the Library and examine them."

We should like to know what Mr. Logan means by "other people." He seems to forget that the government in this country is the people. We hope that some of his medical constituents will enlighten him in the course of the summer. They might also remind him that it is only asked that the books be put in the Government Library. All the expenses attending their use in other places than Washington, are borne by the "other people."

The result of the Senate's action is satisfactory as far as the Library is concerned, but the Museum gets too little. The two institutions should have together $15,000 per annum to make and keep them what they ought to be.

The Sundry Civil Appropriation Bill has passed the House without the insertion of any provision for the National Board of Health. Mr. Ellis, of New Orleans, made an attack on the Board, ridiculing its investigations, claiming that it had tried to create a panic about yellow fever being in New Orleans when the city was free from that disease, and, in short, reiterating the charges of the Louisana Board of Health. In the course of the debate one fact was brought out which we are very sorry to see. Mr. Ellis produced a table showing the expenditures of the Board for investigations into the causes of disease, etc., which table he said was taken from the books of the Board. On being questioned he said the information had been furnished by a member of the Board, and a little later said that he gave it on the authority of the Surgeon-General of the Marine-Hospital Service.

The records of the Board are, of course, public property, and any one has the right to examine them, but that the member of the Board from the Marine-Hospital Service should set to work to furnish material for an attack on the Board on account of its scientific investigations, the results of which have received universal commendation—and that the Surgeon-General of the Marine-Hospital Service should join in this attempt to prevent further work in this direction, is a thing we can hardly credit even upon Mr. Ellis's testimony.

While refusing any appropriation for the Board, the House granted $100,000 to be used in case of epidemic, and to be expended, as was the case last year, under the direction of the Marine-Hospital Service.

We print elsewhere extracts from a letter written by the Mayor of Brownsville, Texas, in which very unpleasant charges are made as to the manner in which this epidemic fund was administered.

No doubt there is another side to this question, but that political considerations governed the ap-

pointments made by Custom House officials to carry out the law, we have no doubt, and the results cannot but be harmful to the cause of preventive medicine.

An attempt will probably be made to amend the bill in the Senate, but the prospect of success is not good. Congress has not yet learned its lesson, and probably it will require the sacrifice of many lives before this is accomplished.

THE ILLINOIS STATE BOARD OF HEALTH.

THAT the Illinois State Board of Health, through the energy of Dr. John H. Rauch, its Secretary, has been of service not only in purifying the State of a large number of incompetent practitioners of medicine, but also by keeping in line certain medical schools otherwise inclined to be lax in their rules of graduation, no one dare deny. It is much to be regretted, therefore, that so soon after having passed its resolution to the effect that hereafter no diploma would be recognized except from schools which require an admission examination in addition to attendance upon at least two annual courses of lectures, it should fail to take explicit action in the case of the Columbus Medical College, after its exposure in so flagrant an offence as the issuing of the Dent diploma. Yet such appears to have been the case.

It seems that the Illinois Board had before it the official statement of the facts by Dr. James E. Reeves, Secretary of the State Board of Health of West Virginia, and the action of his Board in relation to the conduct of this College. No allusion is made to this in the Illinois Board's published proceedings of January 11 and 12, 1883, while mention is made of a communication from Dr. Reeves, stating that a diploma issued by the Baltimore Medical College had been refused recognition by the West Virginia Board. This together with another circumstance is calculated to place the Illinois Board in an equivocal position. The election of Gov. Collum, of Illinois, to the U. S. Senate, caused the accession of Lieut.-Gov. Hamilton to the gubernatorial chair. Now, Gov. Hamilton is the nephew of Dr. J. W. Hamilton, the Dean of the Columbus College, and while this may have had nothing to do with the action of the Illinois State Board, it makes it the more incumbent upon that body to present a satisfactory explanation.

PYROGALLIC ACID IN THE TREATMENT OF PHAGEDENA.

IN a paper presented to the Academy of Medicine recently (*Bull. Gen. de Thérap.*, 30 Janvier, 1883), M. VIDAL urges the employment of pyrogallic acid as a means of arresting phagedenic ulceration—especially of phagedenic chancre. He narrates several cases in which this remedy was entirely successful, when iodoform and other antiseptic applications had failed. He advises it for soft chancre, and sloughing phagedena, and not for sloughing ulcers of tertiary syphils. For a simple soft chancre, Dr. Vidal advises the pomade, as follows: pyrogallic acid, 20 parts; axunge (or benzoinated lard?), 80 parts. Mix.

When the ulcerating surface has fissures, pockets, and sinuses, he prefers the following powder: pyrogallic acid, 20 parts; powder of starch, 80 parts. Mix. Such a powder may be blown by an insufflator into all the folds, and depressions, and sinuses, and thus all parts of the unequal surface be acted on. Whether the unguent or powder be used, the application should be made morning and evening until the character of the sore changes, when iodoform, or any simple dressing may be substituted.

Pyrogallic acid is a toxic substance. Husemann (*Die Pflanzenstoffe*, p. 1005) states that it is not absorbed when inserted into the subcutaneous connective tissue, but gives abundant evidence of its toxic activity when introduced elsewhere. Vidal holds that it may be absorbed by the skin in sufficient quantity to be dangerous, and hence he advises prudence in the applications. It is quite certain that no symptoms of poisoning will be produced when the applications are made as above advised.

THE NEW YORK CODE.

WE learn from an authentic source that a society is being organized in the State of New York, whose object is to maintain the Code of Ethics of the American Medical Association. A large number of the leading members of the profession have expressed their desire to join the society and become active co-workers. This movement is very timely, and will lead to the most important results.

AT the Commencement of the Rush Medical College, of Chicago, last week, Prof. Moses Gunn delivered the valedictory, which was chiefly an attack upon the National Code of Ethics, and upon the Illinois State Board of Health. The wide publication of the address in the daily papers is likely to prove unfortunate, since it is not calculated to further the interests of the College, or to benefit the professional prospects of the author.

It is the opinion of some shrewd observers that the New Code will seriously diminish both the consultation business of its supporters, and the number of students who will seek instruction in the schools with which they are connected. For honest, truth-loving students of scientific medicine can have no sympathy with those who are willing

to degrade their calling by affiliating professionally with medical quacks. On the other hand, the irregular practitioners have given formal notice that they have their own specialists, and that they have no wish to consult with those who are now seeking to obtain their patronage. Thus the advocates of the New Code are likely to find themselves in the position of the greedy dog in the fable, who, in snapping at the shadow in the water, dropped the bit he was carrying, and so lost all.

In the mean time, the ball keeps rolling, and the Rensselaer County (N. Y.) Society last week again did itself honor by repudiating the action of the State Society, at Albany, in reference to the New Code.

It is a significant fact, that the two or three medical journals which last year applauded the action of the majority at Albany, have quickly succumbed to the displeasure of their subscribers at their course, and have quietly abandoned their open advocacy of the New Code.

REVIEWS.

Medical Electricity. A Practical Treatise on the Applications of Electricity to Medicine and Surgery. By Roberts Bartholow, A.M., M.D., LL.D., Professor of Materia Medica and General Therapeutics in the Jefferson Medical College, of Philadelphia, etc. etc. Second edition, enlarged and improved. With 109 illustrations. 8vo. pp. 291. Philadelphia: H. C. Lea's Son & Co., 1882.

Works on electro-therapeutics are by no means few, and the fact that Dr. Bartholow's treatise has so rapidly passed to a second edition is practical evidence of its positive merits. It is free from the two objections which hold against most works on the same subject, namely, that they are either overloaded with the details of cases and procedures, or that they are incomplete. It is comprehensive, and at the same time compact. Valuable additions have been made in the present edition.

Among the features of the book worthy of special mention are, the brief but lucid accounts of apparatus; the exposition of the present medical status of Franklinic electricity, including the adaptation of the Toepler-Holtz machine for the production of nerve and muscle reactions; the presentation of the little known subjects of magneto therapy and thermo-electricity; and the description of Plante's cell, and Trouve's polyscope for storing electricity for medical and other purposes.

Dr. Bartholow's work will largely supplant, for the student and practitioner, the other treatises on electro-therapeutics now before the profession.

Speech and its Defects. Considered Physiologically, Pathologically, Historically, and Remedially. By Samuel O. L. Potter, M.A., M.D. Lea Prize Thesis of Jefferson Medical College. 12mo. pp. 117. Philadelphia: P. Blakiston, Son & Co., 1882.

The chief value of this book lies in a *résumé* of the bibliography of impediments of speech, and an *exposé* of the various tricks and appliances resorted to by itinerant and other professed curers of defects of speech. This historical portion is admirably done and will amply repay perusal by physicians and others interested in the subject. The physiological portion is unsatisfactory, and in part obscure and unreliable. The defects of speech are arranged under quite a formidable series of Greek appellations, and explained in detail. The pathological portion of the essay is not pathological at all, and is confined to a few sentences indicating spasm in some portion of the articulating apparatus as the source of the infirmity. Therapeutically the temporary benefit resulting from many of the well-known rhythmic and other devices for assisting enunciation, is admitted; and the institution of systematic respiratory, vocal, and articulatory gymnastic movements commended as a discipline far more valuable than any other method of treatment

SOCIETY PROCEEDINGS.

MEDICO-CHIRURGICAL SOCIETY OF MONTREAL.

Stated Meeting, February 16, 1883.

The Vice-President, T. G. Roddick, M.D., in the Chair.

The following pathological specimens were presented:

ANEURISM OF ANTERIOR COMMUNICATING ARTERY.

Dr. George Ross narrated the case. A lad aged 17, was admitted into the General Hospital, on the evening of December 18th, in an insensible state, with stertorous breathing. Eyes closed, pupils contracted, muscles of arm and forearm rigid. Legs rigid and straight. From his friends it was ascertained that he had been well up to a year ago, but within this period he has had several severe attacks of bleeding at the nose. Three months ago he is said to have had an epileptic fit, from which he recovered in ten minutes. For eight days has had severe headache, very bad in the forty-eight hours before present attack. Two hours previous to admission he went out into the yard, where he was found in an insensible condition. On the 19th, he remained in the same state. No albumen in the urine. Towards evening the rigidity of the muscles became less. Eyeballs prominent, and there is slight ecchymosis on right upper lid and under ocular conjunctiva. Left pupil is dilated. On the 20th, arms still rigid, legs relaxed. Has had several attacks of clonic spasms in arms and muscles of the back. Cheyne-Stokes' breathing well marked. Ecchymosis has deepened about right eyeball, and is commencing in the left. Temperature is rising. On the 21st, limbs relaxed, opens the eyes but does not appear conscious. Veins of the optic disks very full, no other intraocular changes. Temperature 102°; pulse 125. The following day he was much worse; sphincters relaxed, coma more profound. Temperature 103°. On the 23d, the temperature rose to 105°, and death took place in the afternoon.

The *autopsy* revealed extensive hemorrhage at the base of the brain, involving the meninges, anterior to the optic chiasm, and extending into the longitudinal fissure, and over the anterior part of the corpus callosum. On separating the orbital surfaces of the frontal lobes, an aneurismal sac, the size of a large pea, was seen springing from the anterior communicating artery and partially embedded in the contiguous brain substance, which was a little lacerated. When removed and washed, the sac was found to arise by a small orifice from the anterior communicating artery

close to the right anterior cerebral. It was full of dark blood, and had ruptured at the lower surface, the rent being about two millimetres in length. The hemorrhage had extended along the sheaths of the optic nerves to the eyeballs. The other cerebral vessels were healthy. There was no heart disease.

Dr. Ross remarked on the difficulty of diagnosing the case at first, and of the assistance rendered by the development of subconjunctival ecchymoses. In his experience this was a very rare occurrence in cerebral hemorrhage.

DR. OSLER called attention to the fact of the frequency of aneurism of the cerebral vessels, and to the fact that many cases of apoplexy in young persons were caused by them. This was the eighth instance which had come under his observation in the past few years, and all the specimens had been shown at the Society. Of these, four were of the middle cerebral artery, two of the basilar, and two of the anterior communicating. In seven of them, death was caused by rupture of the sac. He remarked that in cases of fracture of the sphenoidal bone, or in instances such as this, where the hemorrhage occurred in the neighborhood of the optic nerves, the subconjunctival hemorrhages would be more common; but when the fracture was in the middle or anterior part of the orbital plate of the frontal, the hemorrhage was into the more superficial parts of the orbit, and more likely to produce ecchymosis of the lid.

ULCERATIVE ENDOCARDITIS, SIMULATING TYPHOID.

DR. ROSS reported the case; that of a man aged 26, admitted to the general hospital on the 2d, in a state of delirium, with temperature 104°, pulse 100, and respiration 28. Though delirious, he would at times answer questions. Face was flushed, eyes bright, pupils small; expression nervous and anxious. Tongue dry, cracked, and brown; abdomen full; marked tenderness in right iliac fossa; no sore spots. Examination of heart and lungs revealed nothing abnormal. The following history was obtained: Had never been very sound in mind, but has been healthy; was at work on January 29th, when he was taken with a severe chill, followed by headache, vomiting, and nausea. Went to bed that evening; became delirious, and has been feverish, with severe headache, ever since. There have been several loose stools each day. On the night of the 2d he was very delirious, talking loudly, and getting out of bed. Passes feces and urine involuntarily. On the 3d, the temperature was 102°, pulse 125, and weak. On the 4th, after a very bad night, the patient was much quieter, dull, and stupid; face dusky; can get no reply to questions; temperature 103°, pulse very weak; passed stools in bed. Patient gradually sank, and died on the next day—the third after admission, and the eighth of his illness. The heart and kidneys were exhibited. The autopsy showed extensive ulcerative disease of the aortic valves, two of which had fused (congenital), and were sclerotic. The vegetations were soft and recent, and there was a small perforation of one segment. The mitral valve was unaffected. The spleen was about twice the normal size, but presented no infarctions. The kidneys were enlarged, and showed six or eight recent infarctions. In the small intestine there were half a dozen spots of hemorrhagic infiltration of the submucosa, the centre of each occupied by a small white necrotic patch (infarctions). In the left occipital lobe there was a spot of recent red softening, the size of a small apple. No other foci in the brain.

Dr. Ross stated that he had thought the case one of typhoid fever from the mode of onset and the pronounced abdominal symptoms. The only suspicious features had been the bright eye and injected conjunctiva, and if a murmur had been heard a correct diagnosis might have been reached. The experience of a considerable number of cases had now made both physicians and attendants at the General Hospital tolerably alive to the subtleties of this disease, but in none of the previous ones with typhoid symptoms had the course of the disease been so rapid.

In reply to a question by a member, Dr. Ross remarked that the state of the valves was certainly such that a murmur might have been expected, but none was heard when he examined the patient the day after admission. The condition of the vegetations would almost prevent a regurgitant murmur.

DR. OSLER exhibited the characteristic micrococci of the vegetations, stained with aniline blue. In this instance there were a few bead-like chains, such as had been noted by some writers. Their relation to the disease was still in dispute. They are found in the simple warty vegetations and in the outgrowths often met with in old sclerotic valves; indeed, they appear elements common to various endocardial processes which have very different symptoms and arise under different conditions. Valves which are malformed, as in this instance, appear specially prone to be attacked with this form of the disease.

CALCIFICATION OF THE TOOTH-PULP.

DR. OSLER showed, for DR. LOVEJOY, the section of a first molar with the pulp calcified. The tooth was large and not decayed, but was at times so painful that it was thought advisable to extract it. The cavity was filled with a mass of a stony hardness, darker than the dentine, but having much the same appearance. A narrow space separated it from the wall of the cavity. In some animals the pulps become converted into secondary dentine, and in old people progressive calcification is not uncommon. In this case the man was vigorous, middle-aged, with good teeth.

CHYLOUS ASCITES.

DR. ROSS showed a bottle full of milky looking fluid which had been removed from the peritoneum of a lad under his care, who had albuminuric anasarca. The abdomen was much distended, and several pints of fluid were removed. There were no formed elements in the fluid.

DISEASED PLACENTA.

DR. GARDNER exhibited a diseased placenta from a patient who last menstruated on the 12th of August, quickened two days before Christmas and was delivered of a dead macerated fœtus on the 7th of February. The specimen was much shrunken, measuring about eleven centimetres in diameter and one centimetre in thickness. In general the substance was much paler and firmer than that of the normal placenta. There were a number of firm nodules, evidently the result of placentitis or of extravasated, decolorized, and organized blood-clot, according to the views variously held by authorities on the subject. Interspersed between these nodules were a number of cavities varying in size, from a cherry to an almond, filled with recent blood-clot. The membranes were opaque and very friable, a large part remaining in the uterus and requiring introduction of the hand for its removal after the expulsion of the placenta. The patient is the mother of five children, all born at full term after normal pregnancies. During the pregnancy in question she had been œdematous to a slight extent, had suffered from a feeling of general weakness and craving appetite. When first seen by Dr. Gardner, four days before her delivery, she was suffering from violent headache of the frontal and vertical region, evidently of uræmic character, as there were distinct general anasarca and slightly albuminous scanty urine. For

nearly three weeks the fœtal movements had become gradually more feeble, and during the last three days had entirely ceased. At the same time that the movements ceased the uterine tumor sank towards the pelvis and had lost its normal elastic feel. Fœtal heart-sounds were inaudible. The headache appeared at the same time as the cessation of fœtal movements and collapse of the uterus, with renal insufficiency. The fact seems to bear out the pressure theory of uræmia in pregnancy.

Treatment before labor consisted in purgative doses of compound jalap powder, with full doses of bromide of potassium and chloral. As the latter gave no material relief to the headache, it was soon discontinued, and fifteen-minim doses of Battey's sedative solution of opium substituted with marked success. After the uterus was emptied the urine increased in quantity, the headache disappeared, and, with the exception of a slight attack of pleurisy, the patient made a good recovery.

APOPLEXY INTO THE VENTRICLES.

Dr. Armstrong mentioned the case; a man, aged 37, who had consulted him with severe headache, slight intolerance of light, and vomiting. Patient was under treatment for secondary syphilis. In a few days, he felt better and was able to go out. On Saturday, the third, he took supper in the evening, but vomited it, complained of great pain in the head, became comatose, and died at eleven o'clock. A post-mortem revealed extensive hemorrhage into the lateral ventricle, and the blood had also passed into the fourth. The walls of the lateral ventricle were unbroken, and the source of the hemorrhage undetected.

THE TREATMENT OF PUERPERAL SEPTICÆMIA BY IODOFORM SUPPOSITORIES.

Dr. Alloway presented the records of six cases of puerperal septicæmia, three of which had been treated by a new method, viz., the introduction into the uterine cavity of iodoform suppositories. He referred to the care and anxiety which these cases caused to the attendant, the frequent visits necessary if the ordinary method of repeated intrauterine injections is followed, as in general practice the assistance obtained is rarely skilled enough for this. The advantages of iodoform in general surgery were now fully recognized, and it occurred to him that they might be extended to the treatment of the raw placental surface and to the lacerations and bruises of the passages. The site of a separated placenta had been well compared to the stump of a limb after amputation. With this remedy we had the advantages not only of a topical action, but, applied in the manner directed, the effect was continuous, and the vapor, or whatever it was, given off, permeated to all parts. Too often with injections, the superficial parts were cleansed and in an hour or so, unless repeated, the discharges were again fetid. He believed that with the iodoform we could get a more effectual disinfection of the intrauterine cavity in these cases than with the ordinary solutions and the trouble of constant injections was completely obviated. The author referred to the current views on septicæmia, particularly to the formation of a virus by the bacteria in the decomposing discharges, and suggested that if, as Binz has shown, the iodoform controls the activity of the protoplasm of the colorless blood-corpuscles, it may do the same with the bacteria. In carrying out the treatment he used a Sims' speculum, washed out the uterus first with plain or carbolized water, and then, with a tent-inserter, passed the suppository far up into the fundus. He used them of the strength of ten, fifteen, or twenty grains, and usually introduced one night and morning. No poisonous effects had been noted.

The author first read the notes of three cases, two of diphtheria of the passages, which were treated successfully with injections of carbolic acid and Condy's fluid; the third, a very severe case of septicæmia, which he had not treated during the entire illness, but which had had no injections, and terminated fatally.

The cases in which he had used the iodoform were as follows: Mrs. B., aged 23, confined June 20, 1882; fœtus nearly at full term, but had been dead some time and was decomposed; fluids very dark and offensive. Uterus was washed out immediately with carbolic solution, and the nurse was ordered to syringe the vagina with the same every three hours. Up to the twenty-third the patient did well, but in the afternoon of this day she had a chill, and when seen in the evening the temperature was 104.5°, and the pulse 123. There was no pain, discharge slight, a little offensive. The cavity of the uterus was washed out with warm water, and a fifteen-grain iodoform suppository inserted. On the twenty-third the temperature was 101°, pulse 110. Uterus again washed out and another suppository inserted, and in the evening a third. No further chills; patient doing well. On the twenty-fifth the temperature was 99°; same treatment followed. She made a good recovery.

Mrs. E., aged 30, fourth pregnancy, confined September 24, 1882. Easy labor; did well until the 26th, when she had intense perimetric pain and a severe chill; temperature 103.5°, pulse 126; ordered poultices, and gave Battey's solution of opium. Followed same local treatment as in former case. In the evening the temperature was 104°; introduced another ten-grain suppository. 27th, pain gone, temperature 100°; same local treatment morning and evening. 28th, better, continued the suppositories. By the 30th, the temperature was normal and she made a good recovery.

Mrs. G., aged 25, third pregnancy, confined December 13, 1882. Dead twins at the sixth month. Afterbirth came away and seemed entire. Patient has had a series of chills in the past twenty-four hours, and after delivery the temperature was 105°, pulse 100, and she was in a very excited state. A portion of adherent placenta was removed, and grs. xx of quinine were given. On the 14th she was quieter, temperature 103°, pulse 140; uterus was washed out and two ten-grain suppositories inserted. No tenderness. 15th, temperature 100°, pulse 112; same local treatment. On the 16th, had diarrhœa; had no suppository last evening; discharge this morning a little fetid; temperature 103°, pulse 124; two of ten grains each inserted, and in the evening a third. To the 21st, she had one every morning and evening. On the 22d the treatment was stopped; temperature normal.

Dr. Trenholme thought the practice a reasonable one; he had had no experience with the remedy; indeed, he was one of those fortunate ones who have never had a case of puerperal septicæmia in private practice.

Dr. Gardner had used iodoform in lacerations of the vulva and perineum, and with advantage. The tenacity with which it adheres to raw surfaces, and even remains after injections, is a point in its favor. He had used it also in chronic endometritis, and, although it had diminished the pain, no permanent good resulted. He had been in the habit for some time of rendering sponge tents antiseptic with iodoform.

Dr. George Ross referred to diphtheria of the vagina after delivery, and remarked upon its insidious onset in a case which he had treated. He thought Dr. Alloway's suggestion very valuable, and could speak of the benefit he had seen follow in one extremely severe case of puerperal septicæmia. The fetor was removed and a decided improvement manifested within forty-eight hours. He did not think there was any danger of toxic effects in the doses mentioned.

DR. CAMERON spoke of the great influence of iodoform in subduing pain, but believed the special advantages in this form of treatment were the constant presence of the antiseptic in the uterine cavity and the certainty that all parts would be subjected to its action. In the cases reported, some of the benefit might reasonably be attributed to the washings, which should not be neglected in any case.

DR. ARMSTRONG thought that those cases in which the septic trouble was due to decomposition and sloughing within the uterine cavity could alone be appropriately treated in this way.

DR. F. W. CAMPBELL believed that the suppositories could prove of great service, particularly in cases of retention of portions of the placenta.

DR. ALLOWAY stated that he had been induced to lay his limited experience before the Society, in the hope that other members would test the practice. For his own part, he felt much more confidence now in the treatment of these cases. In illustration of the antiseptic powers of iodoform, he showed two bottles of meat infusion, which had been allowed to decompose; into one he had put a little iodoform and the decomposition had been checked, the putrid odor was removed, and the solution rendered, as was very apparent much clearer by the death and subsidence of the bacteria.

BRAINS OF TWO MURDERERS.

DR. OSLER presented the brains of Richards, who murdered a comrade at Sweetsburg, Que., and of O'Rourke, who killed an old man and his daughter, at Milton, Ont. Richards was a hardened criminal, had been in the army, and had been discharged as unfit morally. He cut his throat on the morning of the day fixed for his execution. His brain was large and well developed; the asymmetry between the convolutions and fissures of the hemispheres very slight; the organ was not of the confluent fissure type to any special degree; the secondary and cross sulci were not numerous, and the majority of the convolutions were arranged in a typical manner.

O'Rourke was a man of no education, had had illusions, had served in the penitentiary. The plea of insanity was raised in his defence. His brain was under-sized, the cerebral hemispheres scarcely covered the cerebellum, and there was marked asymmetry between the fissures and convolutions of the two sides. No special degree of confluence of the fissures, except in the right parietal lobe. In both frontal lobes there was a partial splitting of the second gyrus and an approach to the type of four frontal convolutions. The secondary sulci were unusually abundant. The brains were preserved by Giacomini's method.

PROVINCIAL HEALTH ACT.

DR. LAROCQUE, the Health Officer of the city, called the attention of the members to the Act now before the Legislature, and gave a sketch of the progress which had been made during the past few months. The Act provides for the establishment of a Board of Health for the Province, to be composed of three medical men, three commissioners, and one sanitary engineer. He urged the members to do all in their power to get the bill passed this session.

NEW YORK SURGICAL SOCIETY.

Stated Meeting January 23, 1883.

T. M. MARKOE, M.D., PRESIDENT, IN THE CHAIR.

JAMES L. LITTLE, M.D., read a paper on

COMPLICATIONS ARISING FROM UNDESCENDED TESTICLES.

There are three positions in which a testicle may be detained in its transition from the abdominal cavity to the scrotum.

1st. In the abdominal cavity near the internal ring.
2d. In the groin near the external ring.
3d. In the inguinal canal.

A number of such cases have come under my observation. The most common situation has been where the testicle was retained just outside the canal near the external ring. I have met with one case in a child in which both testicles were retained in the abdominal cavity, as no trace of them could be felt in the canal. In this situation a number of cases have been reported in which the testicle has become the seat of malignant disease—no instance of this kind, however, has come under my observation.

Cases where the testicle is arrested just outside of the external ring are not infrequent. In several that I have seen, the testicle could be pushed back into the inguinal canal, but as soon as pressure was removed it would assume its original situation. A few years ago I was called to see a patient in whom a testicle in this position was the seat of gonorrhœal epididymitis. It was a patient of about eighteen years of age, who had been suffering from gonorrhœa for some weeks. His symptoms were very severe; constant vomiting, with intense pain in the groin and lumbar regions. Upon examination, a hard swelling was found situated just outside of the right external ring, with the absence of the testicle from the scrotum. This swelling was about double the size of the testicle of the opposite side, and resembled a strangulated hernia, both in symptoms and appearance. The history, and the absence of the testicle from its normal situation were sufficient for diagnosis.

Second: on August 17, 1868, I was called to see a patient who had a strangulated hernia; his history was as follows: he had suffered from what he supposed was a femoral hernia for many years, for which difficulty he had been in the habit of wearing a truss. The morning on which I was called he had gone out for an early drink, and neglected to apply his truss. The rupture came down and became strangulated. Upon examination I found a tumor about the size of an orange on the right side just above Poupart's ligament resembling in many respects a femoral hernia which had rolled up and over the ligament. Failing to reduce it by taxis, I etherized the patient, and found upon examination that he had an undescended testicle situated just outside of the external abdominal ring, and that the tumor was formed by the distention of the inguinal canal. Failing to reduce it by taxis under the anæsthetic, I cut down through the walls of the canal, and found about ten inches of the gut in a strangulated condition. The seat of the stricture was at the internal abdominal ring. The testicle was lying behind the gut just outside of the external ring. The internal ring was enlarged and gut returned, when the patient made a good recovery. In this case the testicle was normal in size and appearance, and I have no doubt could be easily pushed up into the canal, so that his truss was worn without inconvenience.

The next case, sent to me by Dr. Wm. A. Hammond, is one in which the testicle was retained in the inguinal canal. The patient was twenty-six years of age, and had the following history: He had never noticed anything like a testicle on the right side until three years before he came under observation, when, while exercising on a trapeze, he received a blow on the right side of the abdomen, which gave rise to severe pain, similar to that produced by pressure upon the testicle of the other side. About a month afterward he noticed a small and soft tumor on the right side, just above the external ring. From that time, after any violent exercise, straining, or long walking, the tumor would increase in size and become very painful. After a few days the swelling would subside, but the

tumor would never become as small after an attack as it was before. Last winter the patient wore a truss for some time without any benefit. The tumor gradually increased in size. On examination only the left side of the scrotum was found to be developed, which contained a testicle of normal size. In the right inguinal region was a swelling extending up in the direction of, but some distance above, the inguinal canal. A moderately firm and perfectly movable tumor could be felt. This could be moved so as to lie almost at right angles to its normal situation. Firm pressure upon the upper part of the tumor gave rise to a sensation similar to pressure upon a testicle. The tumor was about four inches long by two broad. The external abdominal ring could be distinctly felt, but was so small that the little finger in invaginating the tissue could not be passed into it.

On November 24th the following operation was performed at St. Luke's Hospital, with all the antiseptic precautions. The coverings of the tumor were rendered as tense as possible by grasping it with my left hand, and an incision of about five inches in length was made over the most prominent part, nearly parallel to Poupart's ligament. The tissues were divided until the peritoneum was reached. This was opened upon a director, and the tumor was then forced out from its bed. Its attachments were composed of folds of peritoneum, extending along its entire inferior surface. A large number of tortuous vessels were seen beneath this peritoneal pedicle, more abundant at the upper extremity than at the other portions. A double catgut ligature was passed through the centre of the pedicle and tied on both sides. Another ligature was applied embracing both halves of the pedicle, and the tumor was then removed. No exploration of the wound, with a view to ascertaining whether it communicated with the abdominal cavity, was made. The deep parts of the wound were brought together with three Lister's leaden-plate sutures, and the superficial wound was united by the ordinary silk suture. The wound united by primary union without any untoward symptom.

On examination by the pathologist of the hospital, Dr. Satterthwaite, this tumor proved to be a round-cell sarcoma. In shape it was a flattened ovoid, while its dimensions were four inches in length by two broad, and one and one-half thick. On section its cut surface was of a pinkish color, simulating brain substance both in consistency and feel. It was enclosed in a coat of peritoneum, which formed its capsule, while in the folds that were given off posteriorly were portions of the vas deferens and spermatic vessels. At its anterior and external portion there was a trace of the normal tissue of the testis.

In conclusion, it seems to me that in all cases where a testicle is situated either in the canal or just outside the external ring, and becomes a source of annoyance to the patient, it would be judicious to advise its early removal.

In the case which I have related, complicated with hernia, I have since regretted that I did not remove the testicle at the time of the operation, for unless it could have been readily pushed back into the canal, a condition which would hardly obtain after the operation, a truss would have been worn with considerable difficulty. The after-condition of the case I have related I have never had the means of ascertaining.

DR. E. L. KEYES had had one case complicated by omental hernia, in which the undescended testicle could not be kept outside of the external ring by a truss, although it could be easily pushed through the opening. The patient had had a number of accidents in the way of pain, and at intervals, when he did not wear a truss, the hernial lump would get down and cause a swelling in the groin, which he had always been able to replace. Finally one of these swellings occurred during the absence of the truss, and the patient failed to replace the lump. He then suffered from symptoms arising from partial strangulation, continuing for a number of months. Dr. Keyes operated upon him, and found that he had a hard portion of omentum strangulated at the internal ring with a testicle just below it. He removed the atrophied testicle, and cut off the piece of strangulated omentum. He ligated the cord very high, and left the pedicle of the omentum in the internal ring, which was entirely filled by it. The operation was performed under antiseptic precautions about ten years ago, and the patient made a rapid recovery. He subsequently wore a truss for a considerable period, after which he experienced no trouble whatever. He had also since been the father of several children. The other testicle was normal in structure and position.

Whether it was justifiable to cut out the testicle in these cases before some emergency required the operation, he was uncertain; he was not prepared to say that he would advise it. He had frequently seen these undescended testicles in young children, and believed that if sufficient care and attention were given, that the testicle might be gradually pulled down, and finally be made to remain permanently outside of the external ring, in a certain proportion of cases, until it developed at puberty, and then no further trouble would follow. But it is exceedingly difficult to get a retentive pad that will functionate satisfactorily, even if the testicle can be drawn down and held outside the external ring with the fingers.

In answer to a question asked by the President, Dr. Keyes said that he had had one case in which he had succeeded in keeping the testicle outside of the external ring, but he was not able to replace it in the scrotum. To succeed in any of these cases required a long time, and great care and patient attention on the part of all concerned. He had failed in the effort several times.

DR. SANDS said that Dr. Little had made one remark which perhaps should be qualified. He having suggested that whenever a testicle, situated in the inguinal canal, became an annoyance, it should be removed. It was well known that the operation for the removal of a testicle situated in the inguinal canal was one of much greater danger than the ordinary operation of castration, which is attended with little risk if it is carefully performed. But when the testicle is situated in the inguinal canal, it is very liable to be surrounded by peritoneum, which may have to be divided in order to remove the tumor; and it seemed to him that such an operation should hardly be performed for the relief of a mere annoyance. He did not doubt, however, the propriety of removing a testicle so situated, when it became the seat of a morbid growth, although under these circumstances, the operation was attended not only with greater risk than the ordinary operation of castration, but with a greater improbability of a complete removal of the disease. He thought that in quite a large proportion of the cases in which it had been done, the malignant disease had already involved the lymphatic glands in the abdominal cavity. Here it might be said that valuable evidence could sometimes be obtained on this point, by manual exploration of the rectum. A man came under his observation, in Bellevue Hospital, some years ago, who entered the institution for the purpose of submitting to castration; the left testicle was very much enlarged, and the diagnosis of malignant growth of the testis was readily established; the tumor was so large, however, that it was suspected the disease had extended into the abdomen. Dr. Sands was unable to settle this point by external examination, on account of the thickness of the abdominal walls, but he found, upon making firm pressure

in the left lumber region, a tenderness and a feeling of resistance, not noticeable upon the opposite side. He removed the doubt by passing the hand into the rectum, when, with great ease, a swelling could be felt in the abdominal cavity, evidently due to infiltration of the lumbar glands: accordingly he abstained from operation.

He recalled another case in which he failed to appreciate the presence of an abdominal tumor in a young man whose testicle he had previously removed for sarcoma. The patient made a good recovery, but months afterward he showed signs of suppression of urine, and on this account he came under observation a second time. Examination of the abdomen failed to discover the cause of the trouble. Various medicines were given to cause the kidneys to act, but they failed. Death occurred, and inspection of the abdomen revealed a large mass of cancer, situated upon the posterior abdominal wall, probably originating in the lymphatic glands. The mass was so situated as to completely prevent the passage of urine through the ureters, and the so-called suppression of urine, was really retention of urine, both of the ureters being greatly distended above the point of obstruction.

He had met with one instance in which the testis had descended beyond its usual position, and was situated in the perineum. The person who was the subject of this malposition was a young man, who complained that he was unable to ride on horseback without suffering from pain, due to pressure upon the misplaced organ, which was of about half the size of the opposite testicle. Dr. Sands performed an operation with the intention of placing the testis in the scrotum, but he found the operation to be impracticable, and therefore removed the testicle, when all unpleasant symptoms disappeared.

DR. LITTLE stated that Mr. Curling gave the same advice in regard to the treatment of undescended testicle as that suggested by Dr. Keyes, and he related several cases in which a truss was used to prevent the testicle from slipping back through the external ring into the canal, and Mr. Curling also advises that in cases where the testicle is situated in the inguinal canal and can be readily pushed back into the abdominal cavity the patient should wear a truss with a pad over the inguinal canal, so as to keep the testicle back in the abdominal cavity, it being a much more comfortable place for the patient to wear his testicle than in the canal.

DR. YALE said that the latter point mentioned by Dr. Little was illustrated in a case which came under his observation in the Presbyterian Hospital. A young man had a partially descended testicle. He had been examined, and had been told that he had a hernia, for which a truss was applied, and it had the effect of crowding the testicle back into the abdominal cavity, but subsequently a strain brought the organ down into the inguinal canal, and he had considerable pain, together with symptoms not unlike those attending strangulated hernia. As the testicle could not be brought farther down, Dr. Yale with considerable difficulty succeeded in returning it within the cavity, when the symptoms were relieved, and no further inconvenience had been suffered from the presence of the testicle in the abdomen.

DR. KEYES said that Godard had directed attention to the fact that the cryptorchid is sterile while a monorchid is not sterile, and that the testicle is more or less damaged if it is retained in the inguinal canal; that those which are retained just within the inguinal canal are in a condition of partial atrophy, and that the other testicle is correspondingly hypertrophied. Whether this partially atrophied testicle is incapable of secreting sperm properly, Dr. Keyes was unable to say. Also whether, if the testicle is in good condition, it would be harmed by being pushed into the abdominal cavity and retained there, he was unable to say. He had met with one cryptorchid, and in that instance the man was potent, and had emissions, but was sterile. His seminal fluid contained no mature spermatozoa.

DR. POST asked if cryptorchids could beget children.

DR. KEYES said that such cases were upon record, but that the children did not generally resemble the father; that is, so far as he knew, all such cases of alleged paternity had been shrouded with considerable doubt.

DR. SANDS thought it would be unsafe to say that testicles were useless in persons who had power of copulation. There is no exception to the rule that where both testicles are removed, the power of copulation remains for only a time. Sir Astley Cooper had recorded one case in which a man had lost both testicles, but retained the power of copulation for perhaps a year, after which the desire and the power gradually ceased. He believed that usually the desire and ability to copulate implied the existence of some testicular elements; although the general fact is that those who have both testicles retained are usually sterile. He should think that if subjects who were sterile had normal desires, and were able to gratify them, the most rational supposition would be that normal tissue of the testicle existed in a greater or less amount, but that the spermatic fluid was not able to make its way into the seminal vesicles. He had met with a singular instance of undescended testicle in the case of a young man upon whom he once operated for strangulated hernia. The case was interesting, as showing that a concealed testicle might give rise to a peculiar form of hernia. The man was twenty-five years of age, and was said to have been addicted to sexual dissipation. His scrotum was empty, and he had a hernia upon the left side which became strangulated. Dr. Sands found, upon proceeding to the operation, that only a very slight protrusion existed at the external abdominal ring, in consequence of its small size. Having divided a stricture at the external abdominal ring, and, as he supposed, pushed the intestine back into the abdomen, he introduced his finger, and discovered that he had not relieved a strangulation which existed at the internal abdominal ring, and that, while only a small portion of the intestine had escaped through the opening in the external ring, a large mass remained in the inguinal canal. The stricture was divided at the internal ring, and he was then able to push the intestine into the abdominal cavity, for which he had first mistaken the hernial sac. A small testis was found in the inguinal canal. The person had a well-developed penis, and had an abundance of hair upon the pubes. He also had a beard. Dr. Sands thought that in most cases in which the testicles were retained and the individual was impotent, there are but few evidences of puberty.

DR. G. A. PETERS asked if a testis retained in the cavity of the abdomen was not quite frequently the seat of malignant disease, or more frequently thus affected in that position than when within the canal, or just external to it.

DR. KEYES remarked that there was an impression to that effect, but he did not believe that the statistics had been sufficient to substantiate it.

DR. LITTLE remarked that cases had been reported in the *Medico-Chirurgical Transactions*, *British Medical Journal*, *Medical Times and Gazette*, and other journals, where undescended testicles have become the seat of malignant disease, and authors, for instance, Gross, in his work on Surgery, state that the danger of the detention of the testicle in the inguinal canal, or abdominal cavity, is that it is prone to become the seat of malignant disease, but no statistics are given to sustain this statement.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting, February 7, 1883.

The President, Alfred Stillé, M.D., in the Chair.

Dr. Charles K. Mills read a paper on

ARSENICAL PARALYSIS,

based on a series of cases of arsenical poisoning which occurred on Nov. 2, 1882, at Norristown, Pennsylvania. The poisoning was brought about chiefly through eating pumpkin-pie, which it was subsequently proved contained a large amount of arsenious acid.

On Dec. 24th Dr. Mills saw one of these cases at Norristown with Dr. E. M. Corson, the physician in attendance. On the third of January, 1883, the case was brought to the Philadelphia Orthopædic Hospital and Infirmary for Nervous Diseases, to be under the care of Dr. S. Weir Mitchell, with the following history.

H. G., æt. 24, single, a lawyer, prior to Thursday, Nov. 2, 1882, was in good health. He was taken sick immediately after having eaten freely of pie which was subsequently found to contain poison. He had an attack of vomiting which lasted a few minutes only. He had several similar spells of vomiting during the afternoon, and from that night until Saturday morning the vomiting was almost continuous. It then began to subside, ceasing entirely Monday afternoon, except that early Tuesday morning he vomited a dark grumous mass. Just before vomiting this mass he had a sensation of constriction or contraction in the muscles of the chest and throat, and the facial muscles were much contorted. He was not purged at any time, in fact, his bowels were not opened from Thursday, November 2d, until Wednesday, November 8th. During the whole time that the vomiting persisted he had but little more pain than would be accounted for by the retching and vomiting. Prostration was very great from the first. Nov. 7th he attempted to get out of bed, but fainted, and remained for some time in a semi-conscious state. About this period he began to have marked fever.

Six days after taking the poison, the patient noticed for the first time a sensation of aching and numbness, chiefly about the knees, which, in a few days, extended towards his feet. Three days later the same sensation began in the fingers of both hands, and soon extended to the wrists, beyond which it never passed. His brain remained unaffected. His legs below the knees were now almost completely paralyzed, and there was some loss of power below the elbows. His face was considerably puffed and swollen. His general condition and symptoms remained without change until four weeks after the ingestion of the arsenic, when he began to suffer great pain. The pains began in the knees, and speedily extended downwards. Aching was always present, but frequently the pains were boring, tearing, or lancinating. They were accompanied by a sensation like that produced by a strong faradic current. Two days after the coming on of the pain in the legs, the fingers and hands also became the seat of aching. In one week the pains began slowly to abate; but, up to the present time, he has had more or less pain, varying very much in character. By the middle of December, the numbness and aching, which had previously been below the knees, had extended above them a distance of several inches. His lower extremities felt as if encased in a cylinder as high as the limits of the numbness. The symptoms in his upper extremities did not change noticeably. The loss of power in the thighs increased with the spreading upwards of the sensory perversion.

The patient was seen by Dr. Mills Dec. 24th, but the notes are from examinations made between January 10th and 17th, nearly two months and a half after the poisoning.

He presented no brain symptoms, and no disturbances of the special senses of sight, hearing, taste, or smell. He was much emaciated. Wasting of the limbs was extreme.

Paralysis below the elbows was marked, but not complete. The extensors and supinators were most decidedly affected. The fingers could only be flexed about one-half. Movements of the thumbs and the small movements of the fingers were impaired. The loss of power was slightly greater in the right limb than the left. At both elbows were marked contractures at about right angles. The angles could be reduced to about 160°, but any attempt to carry the straightening further caused pain in the flexor tendons. Both legs were paralyzed completely below the knees. All movements of the toes and feet were abolished absolutely. The legs in their entirety showed a tendency to rotate outwards, the feet, however, assuming the equino-varus position. Contractures were not present at the knees, but at times the limbs would assume a semiflexed position, these acts of flexure being accompanied by cramp pains in the flexor muscles of the thighs. He had jerking both in the legs and arms not infrequently.

The bowels were very torpid. The urine showed an excess of phosphates; but neither albumen nor sugar was present.

Farado-contractility was abolished in all muscles below both knees. Above the knees, the extensor and flexor groups and the sartorius were examined, and the faradic reaction was found to be greatly diminished, but not wholly absent. The response was better to nerve than to direct muscular applications. The muscles below the knees would not respond to weak galvanic currents. To currents of medium strength they responded, but not normally.

The reactions were those of degeneration. Anodal closing gave the strongest reaction; cathodal closure came next. Slight contractions followed both anodal and cathodal opening. The contractions were at first sluggish, though vigorous, increasing after a few trials, and then quickly exhausting.

In both upper extremities farado-contractility was decreased, but not lost; the diminution was much greater below than above the elbows. Below the elbows the faradic excitability was rapidly exhausted. To the galvanic current the reactions of degeneration were present, but not so decidedly as in the legs. Anodal closing gave stronger reaction than cathodal. With moderately strong currents tetany was produced at the anode.

Both patellar reflexes were abolished. The retraction of the testicle, known as the cremaster-reflex, can usually be awakened by irritation of a certain definite region of the thigh extending from the groin nearly to the knee. Gentle irritation of the skin of the inner aspect of the right thigh and leg of the patient, as far down as the malleolus, caused very vigorous retraction of the right testicle. Sometimes, but not usually, both testicles were retracted. Similar irritation of the left thigh and leg led to movement of the left testicle, which was marked, but not as vigorous as that exhibited by the right from irritation of the right limb. Now and then, in making this test, the unilateral movement of the left testicle, from irritation of the left thigh and leg, was followed a moment later by an imperfect retraction of the testicle of the opposite side. A similar effect was not produced in any of my examinations by irritation applied to the right limb; neither did excitation of one side cause motion in the other side only.

On admission the surface temperature of each calf

was 95° F. He usually complained of his legs feeling to him unduly warm.

Late in November transverse white bands were observed across the finger-nails about two lines from their posterior limits. The nails were not furrowed, but simply showed white markings. As the nails have slowly grown these lines have remained.

The fingers and forearms were hyperæsthetic, but at the same time the patient could not determine with any accuracy as to one or two points on testing him with the æsthesiometer. A similar condition, but more marked, was present in the feet, legs, and as high as the middle of the thighs. The muscles were very sensitive. Applications of hot and cold water were discriminated readily.

The pulse, during the time of these observations, ranged between 107 and 148, and was nearly always more rapid in the morning than in the evening. The respirations ranged between 20 and 24, standing usually at about 24. The temperature ranged between 97.8° F. and 99.8° F., but commonly was not much either way from the normal.

On admission to the hospital the following treatment was instituted by Dr. Weir Mitchell; Applications of ice and hot water, alternately, were made three times daily for ten minutes at a time to his arms and legs from the elbows and knees downward. Surface massage with cocoa-nut oil was used once daily. Ice-bags were applied to the spine for one or two hours twice daily. One grain of the extract of ergot of the new U. S. P. was given every two hours, and this was rapidly increased until thirty grains daily were administered. After continuing the use of the ergot for a week, the patient's stomach became disordered, and tincture of belladonna in doses of five drops every three hours was substituted. Fifteen grains of chloral were administered occasionally, and sulphate of morphia, at first $\frac{1}{25}$th grain, and eventually increased to $\frac{1}{16}$th grain, was ordered, to relieve pain when necessary. He was placed on the ordinary full diet of the hospital, with the addition of milk three times daily and beef-tea twice daily.

Dr. Mills made an examination of the patient to note the effects of treatment on Feb. 7th. He has improved steadily day by day; his general strength has increased; he has regained almost entirely the use of the muscles above the knees; he has also much better use of his forearms and hands, particularly the latter, being now able to pick up small objects. The "wrist-drop" has improved greatly. He has much less pain, aching, and numbness below the knees; the legs below the knees, however, still remain paralyzed, but are not so completely helpless. He has every appearance of progressing steadily to recovery.

Dr. Mills then gave, in a few words, all the information he has been able to obtain as to the symptoms shown by the other victims of the poisoning.

Six others, besides the foregoing patient, were poisoned. One of these was a little boy, four years old, I. S., to whom a piece of the fatal pie was given as a reward for going on an errand. He died within ten hours, and there is no knowledge of observations as to paralysis or other manifestations of involvement of the nervous system.

M. S., a sister of the little boy, ate a very little of the pie, and suffered to some extent, but not seriously.

C. H. G., the father of the patient, died six days after the ingestion of the arsenic. Besides severe gastro-intestinal symptoms, he suffered with pain in his head, back, and limbs, was delirious for some hours, and was almost completely paralyzed.

Mrs. G., mother of the patient, ate a little of the pie and had an attack of vomiting. Two days later she ate a piece of custard, which was also found to contain arsenic, and was attacked with vomiting. A few days later, weakness of the legs, with aching and numbness, came on, and the right foot and leg became swollen and inflamed. She gradually recovered.

Mrs. V. ate a mouthful or two of the pie and custard containing the arsenic, and suffered with vomiting, etc., for three days. She has since had paresis and paræsthesia of the legs.

Mrs. F., who ate freely of the poisoned food, suffered severely from gastro-intestinal symptoms. She has been paralyzed from the elbows to the ends of her fingers and from the knees to the toes. She complained of numbness and coldness in the limbs, and a feeling as if a cord was tied tightly around the waist. She had extreme pain in the paralyzed extremities. She has greatly improved, is riding out daily, can stand without aid, and can even walk a little with assistance. She still has some pain in the hands and in the soles of the feet, but they are not tender to the touch. She has some anæsthesia of the hands and feet, especially of the latter.

A careful analysis of the history and symptomatology of the case detailed, compels Dr. Mills to conclude that in well-marked arsenical paralysis we have to deal with a diffused myelitis, decided motor, trophic and sensory bilateral phenomena being present.

Christison describes two classes of cases of arsenical poisoning in which the victims die early without paralysis, and a third class of what he terms subacute cases, with moderate gastro-intestinal inflammation. "In the later stage these cases are apt to show marked nervous symptoms: coma, epileptoid attacks, mania, tetanus, hysterical seizures, partial paralysis resembling lead paralysis when affecting the extremities; contractures may exist."

In 1881, Popow, of St. Petersburg, published an essay upon the pathological anatomy of arsenical paralysis as produced artificially in animals. The work of Popow was carried on under the guidance of the distinguished neurologist and microscopist, Prof. Mierzeyewski, and Seguin considers his essay as in many respects the most important contribution yet made to the subject. Popow concludes that arsenic, even in a few hours after its ingestion, may cause acute central myelitis or acute poliomyelitis; that in chronic cases pathological changes are found in the white as well as in the gray substance, constituting a diffused myelitis; and that the peripheral nerves remain normal, even three months after intoxication. Seguin gives condensed accounts of a few of the cases reported in the literature of the subject, and also reports three cases of his own, all would be suicides with Paris green. His conclusions are practically the same as those of Popow. According to Seguin, whether the myelitis is strictly arsenical, *i. e.*, caused by the direct effect of the arsenic on the tissue of the spinal chord, or whether it is produced (as are many forms of myelitis) by the irritation of peripheral neves (cutaneous, intestinal, and gastric nerve-endings), is a question which cannot at present be definitely solved, but which presents an interesting field for future research and speculation.

Dr. Mills' attention has been called by Dr. J. H. Lloyd to a case of suicide with arsenic, not before reported, which happened some years ago in Bucks County, and was under the care of the late Dr. Hendrie. Anæsthesia and paralysis were so marked that the man declared that his legs were cut of, and died in that belief.

DR. S. WEIR MITCHELL asked if the urine had been examined with care in the early stages of the case? Of late there had been no evidence of trouble, and if at a former period there was albumen, it was no longer present. Perhaps it was not generally known that

atmospheric changes, in absence of any other assignable cause.

CHICAGO.

(From our Special Correspondent.)

Rush Medical College held its fortieth annual commencement, in Central Music Hall, on the 20th of February. There were 179 candidates graduated as *Doctor of Medicine*. The faculty appeared for the first time in the scholars' robes of the University of London.

Prof. Moses Gunn gave the doctorate address, which was devoted to a discussion of medical ethics.

In the evening of the same day the faculty entertained the Alumni of the College at a banquet at the Grand Pacific Hotel.

LONDON.

(From our Special Correspondent.)

The Meeting of the Clinical Society of London of February 9, under the presidency of Dr. Andrew Clark, was an unusually good one. The two papers read were on surgical cases, and excited a good discussion, and then at the end of the meeting two handy ways of testing urine for albumen were demonstrated.

Subperiosteal Amputation at the Hip-joint.—Mr. Shuter read a paper on this subject, illustrated by cases. On October 16, 1881, he held a consultation with Dr. Samuel West and Mr. Rose, on a patient aged 18, in whom he diagnosed acute necrosis without suppuration in the lower end of the left femur. This had led to septicæmia and secondary inflammation of the left hip-joint. Although my diagnosis was not supported, we were agreed that nothing but amputation at the hip-joint would save the boy's life. The next day the following operation was performed. A circular amputation through the junction of the middle and upper thirds was done, followed by a longitudinal incision on the outer side of the femur down to the bone, the periosteum stripped off and left in the flaps and the whole of the bone enucleated. The patient made a good and rapid recovery. A little more than two months after the operation he had a movable stump, and within six months of the operation he was wearing an artificial limb, on which he could get about very satisfactorily, and continued to do so until a few weeks ago, when I made him discontinue the use of it, in order to get a sinus to heal.

In 1859, Prof. Ollier, of Lyons, after performing many experiments on the lower animals, devised subperiosteal operations on the human subject with the view of getting bony supports to flaps cut for disarticulations. Among his suggestions was an operation similar to the one I performed on the hip-joint.

His case, however, was the first successful subperiosteal amputation at the hip-joint, which had been attended with the formation of bone in the stump, and in which the patient had been able to wear an artificial limb satisfactorily.

Mr. Bryant said the stump obtained by Mr. Shuter was the very best he had ever seen after amputation at the hip-joint; he was, however, of opinion that there had been no reproduction of bone in it, and that the good result was due to the firm attachment of the muscles to the periosteum. The operation would not be possible in all cases, but was evidently a good one where practicable. It appeared to him to be very closely allied to that just described by Mr. Furneaux Jordan.

Mr. Croft said that such a case showed the possibility of complete subperiosted *excision* of the hip, which had been denied by some authorities. He asked Mr. Shuter how he succeeded in cleaning the periosteum from the great trochanter.

Mr. Barker referred to a case in which, after flap-amputation through the thigh, he removed the upper end of the femur, which he found to be diseased, subperiosteally. The stump was a very excellent one, and had a rigid axis of new bone in the centre.

Mr. Cripps agreed with Mr. Bryant, that there was no reproduction of bone in the stump. He thought that the prolongation of the operation entailed by this method, and also by F. Jordan's, were distinct disadvantages in an operation where rapidity was of importance, although the use of Davey's lever had reduced the danger of hemorrhage.

Mr. Pick said that this was the only instance in which he had known a patient after this amputation able to use an artificial limb. The man walked into the room, and walked well on the artificial limb, but evidently moved it very largely, if not entirely, by swinging the pelvis.

Mr. R. Davey related the case of perforation of the rectum from the use of his lever, which has already been reported in The Medical News. He had records of the use of this lever forty times, twenty on each side, and in the cases of amputation the recoveries had been sixty-five per cent.

Mr. Morrant Baker attributed the excellent result obtained by Mr. Shuter rather to the very long skin flaps he had made than to the stripping off of the periosteum.

Mr. Morris referred to the readiness with which periosteum peeled off inflamed bone, and doubted whether this method added to the difficulty of the operation.

Mr. Shuter said that since his own case he had assisted a friend in doing one like it; that case died after three months, and then a mass of newly formed bone was found in the stump. In his case he had not bared the great trochanter of periosteum.

Dr. Clark appointed a committee to examine the case, and report upon (1) the structure of the stump—whether it really contained bone; (2) the mobility of the stump—the power of moving the artificial limb from the hip-joint; (3) the relative value of this and other methods of amputation at the hip-joint.

A Successful Case of Nephro-lithotomy was communicated by Mr. Bennett May, of Birmingham. The patient and calculus were shown.

This case closely resembled that of Mr. Henry Morris, which was the first of the kind, and was communicated to the Society in November, 1880.

It showed an advance in point of size and weight of stone removed, this being three inches long and an ounce in weight.

The patient, a coal miner, thirty-four years of age, had his first symptoms of the disease when sixteen, in the form of severe and characteristic pain in the left loin, which after recurring several times during the next few years, completely left him till twelve months ago. During the interval, blood constantly appeared in the urine after exertion, and this, together with a permanent soapy sediment, leaves no doubt that the stone was present in the kidney all the time, and slowly growing there.

In November, 1881, pain returned with great severity after a hard day's work, and since then he could only live in comfort by avoiding over-exertion. A fast walk, rough work, or drive in a conveyance, brought on an attack of renal colic, which, beginning with rigor and sickness, was attended with severe pain in left loin, radiating down course of ureter in testis and thigh, and after lasting six or seven hours, was followed by copious hæmaturia and frequent micturi-

MEDICAL NEWS of August 19, 1882, caused me to refer to my case-book, wherein I find the following case recorded.

On the sixth day of March, 1876, a boy, about thirteen years of age, well developed, was sitting on a wagon driving a pair of mules along the side of a steep hill; the mules became frightened, ran away, and upset the wagon, landing him on the stony ground. The position of his arm while falling is unknown.

About four hours after the accident I saw the boy and found the left forearm at nearly a right angle with the arm, and a very broad elbow-joint. Examining more closely it was ascertained that the olecranon was not between the condyles, the inner condyle of the humerus very prominent, and by slightly moving the forearm motion was produced on the outer side of the joint.

In reducing the dislocation, an assistant steadied the arm, while I grasped the forearm near the elbow-joint with both hands and made traction, keeping the forearm at a right angle with the arm. During the time I made traction I placed the fingers of my right hand on the inner side of the humerus near the inner condyle, and pressed the ulna and radius inward, when a soft snap was produced, and the patient felt relieved. I could now flex the forearm nearly as much as the opposite healthy arm, but I could not extend it near as much. The joint was still very broad and the inner condyle very prominent. It now occurred to me that the sigmoid cavity of the ulna slipped upon the radial head of the humerus; I therefore again made traction and applied pressure as above stated, when another soft snap was produced like the first, but greater; both of them were audible to the bystanders. I could now extend, flex, supinate, and pronate the left forearm like its fellow on the opposite side, the olecranon process of the ulna and the head of the radius being in their proper position.

The arm was placed in an ordinary sling made out of a handkerchief. In a few weeks the patient could make full use of his arm, and about one year after the accident I saw the patient with full use of the arm.

I think the sigmoid cavity of the ulna rested on or above the outer condyle of the humerus. The first soft snap was undoubtedly produced as above explained, and the second snap by the sigmoid cavity of the ulna slipping into the trochlear surface of the humerus.

I am sorry that I cannot report the case more in detail, as I ought to have done at the time of the accident, but I did not search the literature of the subject and therefore did not know the rarity of such cases.

Very truly yours,

WESLEY C. STICK, M.D.

GLENVILLE, YORK CO., PA.

DEATH FROM CHLOROFORM.

To the Editor of THE MEDICAL NEWS.

SIR: The well known views of "THE NEWS" in regard to the comparative merits of ether and chloroform, left no room for surprise at the generally unfavorable editorial notice you were pleased to give my case of "Death from Chloroform," published in your journal of February 17th. There are, however, two points in regard to which justice to myself demands that I should make reply. First, That two ounces of whiskey administered at an interval of twenty minutes should be considered *large doses* of alcohol, and sufficient to depress the heart of an old toper, is a statement as surprising to me as it will be to thousands of practitioners who constantly use the drug with a view to producing the opposite effect. Second, Your strictures on the open towel cone are based on the assumption that it is held down over the patient's nose after the drug has been poured in, and they are perfectly justifiable from that point of view. The fact is, however, that it is with us always held at some distance from the face and waved back and forth, thus ensuring a diluted atmosphere. It is a suggestive fact also, that in the only other death from chloroform which has ever occurred in the University Hospital, where the drug has been used since its introduction into practice, and which took place only a few weeks prior to my unfortunate case, no stimulant was given previous to the inhalation, and the drug was administered by means of an apparatus (Junker's) whose chief merit is that it dilutes the atmosphere thoroughly before the patient inhales it.

I may be allowed to add, that to my ear, the suggested regulation by law of the anæsthetic agent to be used by surgeons smacks more of the fourteenth than of the nineteenth century.

Very Respectfully,

J. EDWIN MICHAEL, M.D.

245 MADISON AVENUE, BALTIMORE,

CLIMATE IN THE TREATMENT OF ALBUMINURIA.

To the Editor of THE MEDICAL NEWS.

SIR: Since reading the admirable editorial on "The Hygienic Treatment of Albuminuria," which appeared in THE MEDICAL NEWS of February 10, 1883, I have felt a keen desire to know something further of your views in relation to the curative effects of climate in this disease. I would like to know especially whether "a Southern dry climate" is best adapted to all forms of chronic Bright's disease; whether in some forms the warm, *moist* climates of Florida or Madeira might not be more beneficial. Finally, in the absence of reliable, published statistics on the subject, whether you can tell me what special, exact locality, in our own country, either in the Southern Atlantic, Gulf States, or Southern California, will furnish the equable, warm and dry climate so much to be desired. By answering these queries, you will no doubt afford much satisfaction to many of your readers and oblige,

Yours Respectfully,

S. Q. LAPIUS, M. D.

NEWS ITEMS.

WATERBURY, CONNECTICUT.

(*From our Special Correspondent.*)

WINTER CHOLERA.—Many cases of the "winter cholera" have occurred here. Fully two hundred and fifty cases were reported as occurring in one week. Cases are continually appearing, but not so many now as there were at first. At the time of its first appearance it was extremely cold, but since then we have had all kinds of weather, which, however, does not seem to make any difference. At first it seemed plausible to lay it all to the snow water in our city reservoirs, but on second thought it was hard to believe that snow water had anything to do with it, inasmuch as there were nearly two feet of ice on the surface of the reservoirs. Cases are reported where tea has been used exclusively, all the water that was used having been boiled. No cases have been reported as occurring in children; all have been adults, both sexes alike affected. Symptoms resemble those of ordinary "summer complaint," and are readily controlled by anodynes. No serious cases have been reported, in fact, the city is freer from sickness, other than this, than it has been in several years. We are inclined here to lay it to

atmospheric changes, in absence of any other assignable cause.

CHICAGO.

(*From our Special Correspondent.*)

Rush Medical College held its fortieth annual commencement, in Central Music Hall, on the 20th of February. There were 179 candidates graduated as *Doctor of Medicine*. The faculty appeared for the first time in the scholars' robes of the University of London.

Prof. Moses Gunn gave the doctorate address, which was devoted to a discussion of medical ethics.

In the evening of the same day the faculty entertained the Alumni of the College at a banquet at the Grand Pacific Hotel.

LONDON.

(*From our Special Correspondent.*)

The Meeting of the Clinical Society of London of February 9, under the presidency of Dr. Andrew Clark, was an unusually good one. The two papers read were on surgical cases, and excited a good discussion, and then at the end of the meeting two handy ways of testing urine for albumen were demonstrated.

Subperiosteal Amputation at the Hip-joint.—Mr. Shuter read a paper on this subject, illustrated by cases. On October 16, 1881, he held a consultation with Dr. Samuel West and Mr. Rose, on a patient aged 18, in whom he diagnosed acute necrosis without suppuration in the lower end of the left femur. This had led to septicæmia and secondary inflammation of the left hip-joint. Although my diagnosis was not supported, we were agreed that nothing but amputation at the hip-joint would save the boy's life. The next day the following operation was performed. A circular amputation through the junction of the middle and upper thirds was done, followed by a longitudinal incision on the outer side of the femur down to the bone, the periosteum stripped off and left in the flaps and the whole of the bone enucleated. The patient made a good and rapid recovery. A little more than two months after the operation he had a movable stump, and within six months of the operation he was wearing an artificial limb, on which he could get about very satisfactorily, and continued to do so until a few weeks ago, when I made him discontinue the use of it, in order to get a sinus to heal.

In 1859, Prof. Ollier, of Lyons, after performing many experiments on the lower animals, devised subperiosteal operations on the human subject with the view of getting bony supports to flaps cut for disarticulations. Among his suggestions was an operation similar to the one I performed on the hip-joint.

His case, however, was the first successful subperiosteal amputation at the hip-joint, which had been attended with the formation of bone in the stump, and in which the patient had been able to wear an artificial limb satisfactorily.

Mr. Bryant said the stump obtained by Mr. Shuter was the very best he had ever seen after amputation at the hip-joint; he was, however, of opinion that there had been no reproduction of bone in it, and that the good result was due to the firm attachment of the muscles to the periosteum. The operation would not be possible in all cases, but was evidently a good one where practicable. It appeared to him to be very closely allied to that just described by Mr. Furneaux Jordan.

Mr. Croft said that such a case showed the possibility of complete subperiosted *excision* of the hip, which had been denied by some authorities. He asked Mr. Shuter how he succeeded in cleaning the periosteum from the great trochanter.

Mr. Barker referred to a case in which, after flap-amputation through the thigh, he removed the upper end of the femur, which he found to be diseased, subperiosteally. The stump was a very excellent one, and had a rigid axis of new bone in the centre.

Mr. Cripps agreed with Mr. Bryant, that there was no reproduction of bone in the stump. He thought that the prolongation of the operation entailed by this method, and also by F. Jordan's, were distinct disadvantages in an operation where rapidity was of importance, although the use of Davey's lever had reduced the danger of hemorrhage.

Mr. Pick said that this was the only instance in which he had known a patient after this amputation able to use an artificial limb. The man walked into the room, and walked well on the artificial limb, but evidently moved it very largely, if not entirely, by swinging the pelvis.

Mr. R. Davey related the case of perforation of the rectum from the use of his lever, which has already been reported in The Medical News. He had records of the use of this lever forty times, twenty on each side, and in the cases of amputation the recoveries had been sixty-five per cent.

Mr. Morrant Baker attributed the excellent result obtained by Mr. Shuter rather to the very long skin flaps he had made than to the stripping off of the periosteum.

Mr. Morris referred to the readiness with which periosteum peeled off inflamed bone, and doubted whether this method added to the difficulty of the operation.

Mr. Shuter said that since his own case he had assisted a friend in doing one like it; that case died after three months, and then a mass of newly formed bone was found in the stump. In his case he had not bared the great trochanter of periosteum.

Dr. Clark appointed a committee to examine the case, and report upon (1) the structure of the stump—whether it really contained bone; (2) the mobility of the stump—the power of moving the artificial limb from the hip-joint; (3) the relative value of this and other methods of amputation at the hip-joint.

A Successful Case of Nephro-lithotomy was communicated by Mr. Bennett May, of Birmingham. The patient and calculus were shown.

This case closely resembled that of Mr. Henry Morris, which was the first of the kind, and was communicated to the Society in November, 1880.

It showed an advance in point of size and weight of stone removed, this being three inches long and an ounce in weight.

The patient, a coal miner, thirty-four years of age, had his first symptoms of the disease when sixteen, in the form of severe and characteristic pain in the left loin, which after recurring several times during the next few years, completely left him till twelve months ago. During the interval, blood constantly appeared in the urine after exertion, and this, together with a permanent soapy sediment, leaves no doubt that the stone was present in the kidney all the time, and slowly growing there.

In November, 1881, pain returned with great severity after a hard day's work, and since then he could only live in comfort by avoiding over-exertion. A fast walk, rough work, or drive in a conveyance, brought on an attack of renal colic, which, beginning with rigor and sickness, was attended with severe pain in left loin, radiating down course of ureter in testis and thigh, and after lasting six or seven hours, was followed by copious hæmaturia and frequent micturi-

tion for the next day or two. There was permanent turbidity of the urine from pus and phosphates, but the amount was subject to frequent aggravation.

Operation was done October 20, 1882. The incision differing from the ordinary colotomy one, in being higher up so as to skirt the last ribs as well as more internal.

Manipulation failed to make out a stone, but acupuncture detected it at once. The kidney substance was incised in a vertical direction until the wound appeared large enough to permit the extraction of the stone, which was accomplished by a scooping action of the forefingers and gentle traction on its smaller end. Bleeding of a serious character was profuse, but controlled by pressure. The parenchyma of the kidney appeared healthy; there was no appearance of pus or a thickened sac, and the cavity after removal was felt to be free from fragments. For the first twenty-four hours there was intense pain and some shock, and the contents of bladder, drawn off by catheter, were nearly half blood. On the following day urine began to flow through lumbar wound, and its becoming strongly ammoniacal caused the abandonment of the Listerian dressing which was originally used. For the first week alone one-third of the entire secretion must have come in this way, but it ceased entirely on the twenty-first day. The wound, which had been well drained from the outset, healed rapidly, and was quite sound at the end of the fifth week, never showing any tendency to the formation of a urinary fistula. At the beginning of the second week there was a slight attack of pleurisy with effusion on the same side.

The urine has slowly returned to a nearly normal standard; blood-staining disappeared after four or five days, but it remained very turbid with pus, phosphates and débris, and strongly ammoniacal for some time after operation. Five weeks afterwards it was neutral when in a fresh state, and in another fortnight the turbidity was nearly gone. Ten weeks after operation it was quite acid and very faintly opalescent. It has varied a good deal since then. Up to the present time the latest report (January 31st) is that it is still opalescent and turbid, with a small quantity of pus and phosphates.

Jan. 31.—He has tested his recovery by active exercise and numerous rides by rail. He feels perfectly restored to health and free from pain, and fit for active work, but has not yet ventured into the coal-pit.

Remarks.—Diagnosis was not very difficult to establish, the symptoms being sufficiently distinct from those of stone in the bladder. The only embarrassment resulting from his voiding a stone two days prior to operation, but the patient himself experienced no relief in consequence.

Operation.—It was found convenient to divide the edges of both erector and quadratus muscles. The kidney fell forwards, and by its recession, when touched, increased the depth of the wound to something considerable, and it was perhaps owing to this cause that the stone could not be palpated. The fingers, retained in the wound whilst being made and during extraction of stone, acted as a plug and arrested bleeding, which would otherwise have been very profuse. The principal feature of interest is the question of completeness of ultimate recovery and of restoration of the kidney as a healthy working organ, after the infliction of such severe injury, by the presence of so large a stone and by the operation. From the state of the urine for a long time, there must have been some degree of pyelitis, but there was no visible destructive change at the time of operation, and to that fact, which has been pointed out in the discussions of this Society, his recovery is no doubt due. Had the condition been otherwise, excision of the kidney would have been indicated. He is quite well now, but the further history of his kidney and the state of its pelvis will be an object of interest. Benzoate of ammonium had been given in large quantities, with the object of neutralizing the alkalinity of the urine, and thus lessening the risk of phosphatic incrustation.

The stone appeared to consist largely of a crystalline phospate of lime, but it probably contained one or more nuclei of oxalate.

Mr. Howse had recently performed the operation, and removed a small oxalate stone weighing twenty-six grains. He could only detect this stone when he pressed his finger on the anterior surface of the kidney, and he urged that in all exploratory operations the kidney should be thus examined.

Mr. Clement Lucas said that it was necessary to distinguish between cases of stone in practically healthy kidneys, and stone in disintegrated kidneys. The latter cases were best treated by nephrectomy.

Mr. Morris thought the exploration of the kidney from the front added to the danger of the operation, and should not be undertaken till other means had failed.

Mr. Bennet May said that it would have been hardly possible in his case to explore the front of the kidney, owing to the depth of the viscus. But he found that pressure upon the abdomen from the front did not fix the organ, a plan which Mr. Morris had advocated.

A Handy Way of Testing Urine.—Dr. Parry showed some small pellets made of sodic ferrocyanide and citric acid, for testing urine. For use, one was taken and crushed in a fold of clean paper, and the powder dropped into a test-tube. Urine to the height of an inch was then poured in and gently shaken, when at once a white precipitate is obtained if albumen is present. Neither the reaction of the urine, nor the presence of phosphates in excess interferes with the test. Like nitric acid, these pellets cause a precipitate of any oleo-resinous matter present in the urine.

Dr. Oliver showed his urinary test-papers. They are small slips of paper which have been soaked in solutions of one or other of the following reagents, and allowed to dry. The reagents are, potassio-mercuric iodide, potassium ferrocyanide, picric acid, potassio-mercuric, iodocyanide, and sodium tungstate. Similar papers saturated with citric acid are supplied with them. For use, the urine to be examined is first acidulated by one of the citric acid papers, and then one of the others is dropped in, and albumen, if present, at once appears as a white opalescent cloud, or as a flocculent precipitate about the paper. Both methods were evidently very simple and handy.

North-eastern Ohio Medical Association.—At the annual meeting of this Society held at Akron, on February 6th, the following officers were elected for the ensuing year:

President.—Dr. J. W. Underwood, of Akron.

First Vice-President.—Dr. R. A. Vance, of Cleveland.

Second Vice-President.—Dr. B. P. Longhead, of Vonidham.

Recording Secretary.—Dr. L. S. Ebright, of Akron.

Corresponding Secretary.—Dr. A. K. Fouser, of Akron.

Treasurer.—Dr. E. W. Howard, of Akron.

Smallpox at Berlin, Wis.—The disease appeared about the middle of January, and since then, thirty-three cases have occurred. The contagion spread to the schools through the attendance of the children of a Pole, who is reputed to have dug up infected clothes after they had been disposed of by burial, and carried

them to his house. One of his children took the disease and died without medical attendance, the others continuing to go to school as usual. The health authorities are using every means to prevent its further spread, but its prevalence among citizens of Polish extraction, who are generally averse to vaccination, operates greatly against their efforts to suppress the contagion.

Porro's Operation.—Prof. Novi, on December 2, 1882, performed Porro's operation in the Maternity Hospital, in Naples: both mother and child were saved.—*Gazzetta Med. di Torino*, February 5, 1883.

Quarantine Against Baltimore, Md.—On January 31, the Colonial Government of Jamaica, gave public notice that the Governor, with the advice of the Privy Council, had declared the port of Baltimore, Md., to be an infected port within the meaning of the quarantine law of 1869.

The Death of a Well-known Dwarf.—Mrs. Burnell, a remarkable dwarf, who has been on exhibition in nearly all the leading museums in the United States, died in New York last Saturday, in the twenty-seventh year of her age. She was born on October 18, 1856, in Richmond, Vt. Her father was a dwarf, but her mother was a woman of ordinary size. In January, 1880, she was married. In September, Dr. Elliott Richardson, of the University of Pennsylvania, successfully performed the Porro-Müller Cæsarean operation upon her, and reported the case in the *American Journal of the Medical Sciences* for January, 1881. Her child, through careful nursing, developed into a strong boy, and he has been her constant attendant at the museum at which she has been exhibiting. He is now two and a half years of age, and is nearly as large as his mother, who at the time of her death was thirty-nine inches in height, and weighed forty pounds.

Mrs. Burnell's death resulted from a complication of diseases—mainly Bright's disease.

The Brownsville Quarantine.—Hon. Thomas Carson, the Mayor of Brownsville, Texas, has written a letter to the Mayor of Pensacola, in reply to some queries of the latter officer as to the workings of the *cordon sanitaire* established around Brownsville last fall, from which it appears that he is by no means favorably impressed with the workings of the new system.

He objects to "the arbitrary assumption of control of quarantine matters by Dr. Murray [of the Marine-Hospital Service], and his attempt to override the local health authorities, the inconvenience of the useless *cordon*, and the injury caused by that institution when, as our election-day approached, it drifted into a mere political machine, and was used for the purpose of facilitating the election interests of candidates supported by the Custom House of this district. Two days after the election it was disbanded. On election-day sixteen of its members were interested as candidates or occupied as supervisors of election and deputy marshals, and the remainder as runners or supporters."

He claims that the nurses brought by Dr. Murray from Galveston "were chiefly a lot of drunken rowdies, picked up apparently at haphazard, and their treatment of the sick was such that the people became alarmed, and would no longer permit their sick to be sent to the hospital."

"From small beginnings, which were overlooked because of the attention of the officials being engrossed in caring for the sick and destitute, Dr. Murray gradually assumed supreme and exclusive control in quarantine matters. . . . . No provision was made by him for keeping persons in quarantine or isolation; he simply declared non-intercourse, and when the local authorities sought to mend the situation, he scouted their authority, and threatened to bring United States troops to sustain his pretensions. Driven from this position, he practically retired from the town, but continued to exercise despotic authority on the line of his *cordon*."

"There were no refuges within the lines of *cordon*. Two points were designated about thirty miles apart, where those wishing to pass out were ordered to go and remain for ten days. At each of these two points a house was provided, but no provisions or anything but mere shelter. So far as I can learn, about six persons availed themselves of these to get through the *cordon* during the entire period of its existence."

"The line of the *cordon* was about seventy miles long, and there were twenty-eight guards on it. Most of them knew nothing of the topography of the country." "The guards were named by the deputy collector of customs, the leader of the 'Ochiltree movement,' and they supported Ochiltree to a man. . . . . Republican canvassers could pass the *cordon* guards with little or no detention. Democratic ones could not."

Endorsement of the National Board of Health by the New York County Medical Society.—The Medical Society of the County of New York appointed a committee, with power, to prepare and forward resolutions concerning the National Board of Health, its work, its continuation, and the annual appropriation for its support. The committee submitted the following report, which was adopted, and ordered sent to the Secretary of each County Medical Society in the State, with the request that the several Societies take similar action without delay:

Whereas, The several Acts of Congress constituting and organizing a National Board of Health, with power to investigate the sources of disease among the people; to prevent the introduction of contagious and infectious diseases into the United States from foreign ports, and their spread from one State to another; to coöperate and aid State and municipal boards of health in the control and suppression of epidemic diseases; and to publish a weekly bulletin of the public health of the cities of the United States, and of the foreign ports of the world which have commercial relations with this country, were regarded by the medical profession as admirably adapted to secure the aid of the general government in the prevention of the importation and spread of those foreign pestilences which have so often devastated large portions of the country in spite of the efforts of local boards of health; and

Whereas, The National Board of Health has discharged the important trusts committed to its care with such fidelity and efficiency as to have won the commendations of the financial officer of the government, and the favor and support of sanitary authorities in this country and Europe; and

Whereas, This Society deems it of the greatest importance that the General Government maintain the National Board of Health in all its integrity and efficiency, as the great central power of the government, ready to coöperate and aid State and municipal boards of health in the prevention of the introduction of contagious and infectious diseases into this country, and their spread from one State into another, and to perform such other duties as the several Acts of Congress impose; therefore

Resolved, That this Society earnestly requests the members of Congress from this State of New York, to use their effort to secure the repeal of the tenth section of the law, of June 2, 1879, entitled an Act to prevent the introduction of contagious and infectious diseases

into the United States, whereby the act is made to expire on the 2d of June, 1883.

Resolved, That this Society also urge the members of Congress from the State of New York, to use their efforts to have adequate appropriations made by Congress for the continuance of its work of investigating the causes of disease, of coöperating with State and local boards of health, of carrying out the immigration inspection service, and of publishing the bulletin.

GUARDING AGAINST THE SPREAD OF EPIDEMICS.—The Swiss Confederation has passed a law entitled "Swiss Federal law relating to the measures to be taken against epidemic diseases threatening general danger," the general principles of which are as follows: 1. The law applies for the present only to smallpox, Asiatic cholera, spotted typhus, and pest. 2. The law is to be executed by the Cantons (corresponding to our States), and the Federal Council is to supervise the methods employed, for which purpose the Cantonal laws and regulations on this subject are to be submitted for approval by the Council. 3. Whenever a physician observes a case of one of the diseases mentioned above he must at once inform the local authority and also the sanitary authority. In those places where any one may practice medicine this obligation falls upon all persons caring for cases of these diseases, and in case a person is not under medical treatment the head of the family or the householder must report the facts as above.

4. Every person affected with one of these diseases must be isolated as soon, and as completely, as possible. The same is to be done with the persons having charge of such a case. If he desires it, the patient may be authorized to remain in his own house on condition that the directions concerning isolation can be properly carried out. This isolation must continue until the case is certified to by a physician, or until the patient, living or dead, has been carried elsewhere, and the prescribed disinfection has been carried out. Persons diseased, but who, without being to blame, must be submitted to isolation and are thus deprived of their wages, have the right of claiming an indemnity. The transportation of persons affected with these diseases shall, in no case, be made by public vehicles. The purchase of soiled or stale linen, or of second-hand clothing, or rags, is forbidden in every locality where these diseases prevail.

5. Every child born in Switzerland shall be vaccinated in the first, or at the latest, the second year of its age. This vaccination shall only be delayed for special reasons certified to by a physician. Children who have not been vaccinated, born abroad and brought into Switzerland, shall be vaccinated as soon as possible, and the fact of vaccination shall be certified to by a legally authorized physician. No child shall without this certificate be admitted to any school, public or private.

6. If scarlet fever, diphtheria, typhoid, typhus fever, dysentery, or puerperal fever prevail in an epidemic form, the Cantonal authorities may apply the above-mentioned regulations concerning preventive measures—an obligation to report cases, isolation, and disinfection—to these diseases also.

7. The Confederation should bear one-third of the expenses caused by the erection of hospitals as places for isolation, or for the costs demanded for the establishment of buildings to receive persons not affected, but for observation.

8. The provisions of this law are to be enforced under penalty of a fine of not more than a thousand francs in grave cases, and imprisonment for six months may be added to this. In case of a second default the maximum penalty may be doubled.—*Sanitary Engineer*, Nov. 30, 1882.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending February 17th, indicate that cholera morbus and typho-malarial fever have increased, and that scarlet fever, consumption, intermittent fever, measles, and tonsillitis have decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during the week ending February 17th, and since, at 14 places, scarlet fever at 9 places, and measles at 9 places.

A correspondent reports what he thought was a case of arsenical poisoning. Face, eyes, hands, and feet swollen, skin pale and cool, great fulness of the head, uneasiness of the stomach, gaseous eructations, and loss of appetite, soon regained. Analysis of substances supposed to contain the poison demonstrated absence of any, and it was suggested that acute Bright's disease caused the symptoms. Other cases, presenting similar symptoms have been reported, some of them supposed to be epidemic influenza. Perhaps if physicians make careful examination of the excretion from the kidney in such cases, it may lead to useful knowledge respecting the disease now prevalent. One physician reports that such examination, made because of unusual prevalence of partial suppression, showed absence of albumen.

OBITUARY.—On February 1st, in the 74th year of his age, PROF. VON SIGMUND. Prof. Sigmund was born in Schässburg, in 1810, received his medical education in Pesth and Vienna, and was appointed Extraordinary Professor of Syphilis in 1845, but did not obtain the full professorship until 1869. His name is well known as one of the most distinguished German syphilographers.

—— Died, in the 56th year of his age, PROF. CARL VON HECKER. Prof. von Hecker was born in Berlin on May 8, 1827, received his medical education in Berlin and Heidelberg: after serving in the army during the Schleswig-Holstein war, he removed to Vienna in 1850, where he studied gynecology and obstetrics, and on his return to Berlin was made assistant to Von Busch, at the obstetrical clinic. In 1858 he was called to Marburg to the chair of obstetrics, as successor to Hüter, though he was soon afterwards called to Munich, to the professorship of obstetrics, a position which he occupied up to his death. His communications to the literature of gynecology and midwifery are numerous and valuable.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 19 TO FEBRUARY 26, 1883.

HEIZMAN, CHARLES L., *Captain and Assistant Surgeon.*—To be relieved from duty in the Department of the Columbia.—*S. O. 12, Department of Columbia, February* 8, 1883.

TESSON, L. S., *Captain and Assistant Surgeon.*—To be relieved from duty at Fort Clark, Texas, and assigned to duty at Fort Ringgold, Texas, as Post Surgeon.—*Par. 5, S. O. 20, Department of Texas, February* 21, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

THE DIFFERENTIAL DIAGNOSIS OF DEMENTIA PARALYTICA, OR GENERAL PARALYSIS OF THE INSANE.

A Clinical Lecture, delivered at the Hospital of the University of Pennsylvania, December 1, 1882,

BY H. C. WOOD, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, AND CLINICAL PROFESSOR OF NERVOUS DISEASES IN THE UNIVERSITY OF PENNSYLVANIA.

GENTLEMEN: I shall bring before you to-day an interesting case. The history is that until June last he was perfectly well, and as far as we can make out —which is a very important proviso—never suffered from specific disease. At that time he began to have occasional headaches; these gradually became worse, but finally they disappeared entirely, and he began to worry about his business, and to be in some respects a changed man, and gradually developed the symptoms from which he is at present suffering, and which I shall detail later in the lecture.

Let me begin by stating that this is a case in which the great interest centres on the diagnosis; and that the point which I shall discuss at some length is, whether this man is suffering from the disease known as general paralysis of the insane—dementia paralytica, or, as it is sometimes called, paresis—or from some other affection.

As many of you perhaps know, there are in fully developed cases of dementia paralytica three sets of symptoms which are especially marked, and which when present are certainly very characteristic. These symptoms are, first, those referable to the mental condition; second, those referable to the moral condition; and, third, those referable to the motor condition, including under this head those symptoms connected with speech, and which are partially due to motor defects, and partially the result of mental depreciation.

If you examine a typical case of this general paralysis of the insane, the first thing that will attract your attention is the peculiar delirium of grandeur, as it is called. The man imagines that he is some great being; sometimes he believes that he is the czar, or the emperor of France, or the president of the republic; and sometimes the Almighty himself. This delirium is not necessarily connected with the idea that the person is somebody else than he is, but may be shown in a belief in the greatness of his own personality. He believes that he is very rich, owns millions; or he may think that he has great power; he will hold out his right arm and tell you that by the power of that mighty arm he is able to overcome multitudes of armies. In some way, in those cases where the disease is typical, there is this delirium of grandeur. It is, however, a mistake to say that the delirium of grandeur is proof that the patient has dementia paralytica, for undoubtedly it may be associated with other diseases, as with a form of ordinary insanity; and I am sure that I have seen it in syphilis of the brain; it is also said occasionally to be seen imperfectly in chronic alcoholism. Then, again, there are cases of general paralysis in which this delirium is not present; there is a class of cases in which the symptoms are those of depression, of hypochondriasis, rather than those of delirium of grandeur. The patient is worried, is apt to grow apathetic, and to be depressed continually.

The second set of symptoms connected with dementia paralytica are those referable to the emotions. These are of great importance, because they may manifest themselves before any other symptoms. The patient's temper changes; the least opposition throws him into a violent rage; he is excessively irritable, and sometimes exhibits an erotic tendency. Emotional excitability, remember, is not an evidence of power, but of weakness. A man has the power of self-control just in proportion as his upper cerebrum is in a condition of integrity, and is habitually able to dominate and control the lower nervous apparatus. Therefore, when we find a man changing his nature, becoming irritable and easily excited, we know that he is in a condition in which there is depression of the upper nerve-centres. This depression or weakness may be simply from exhaustion, or it may be from commencing organic disease.

To complete this outline picture of the disease, it is necessary to say a few words in regard to the motor symptoms. These consist in a progressive weakness, associated with changes in the power of speech. It is frequently stated that patients with this disease first lose power in the legs, and then in the arms, but this is not true. This is simply because the weakness in the legs is first noticed. If the man is engaged in some employment requiring delicate movements of the fingers, he will first complain of loss of power in the hands, and later in the legs. In the early stages of the disorder there is not so much a loss of power as a loss of control, or of coördination; the man who can walk miles, or lift heavy weights, can not perform delicate movements with his fingers.

The changes which occur in speech are twofold: first, simple slowness of speech, due to mental depreciation; second, a peculiar form of expression known as scanning speech, which is very characteristic, and which is due more to loss of motor power than to mental depreciation. When a man in advanced general paresis is suffering from mental depreciation, you will find that he answers very slowly. You ask, "Where were you this morning?" He says, "I—was—down—town." This is because he does not think quickly, because he has lost the power of active intellectual movement, so to speak, and his words come slowly. Another man suffering from this same disease will, in answer to your question, say, "I walked down town to-day." His words may come fast enough, but he answers with a regular, rhythmical, up-and-down movement; separating his syllables, and having an enunciation in which certain sounds, especially the A sounds, are thrown out with great force and length, while certain other sounds, as the labials, are dropped. During the effort of speech in such a case you will notice a peculiar trembling, almost choreic, in the muscles about the mouth.

I shall ask this man a few questions, to see if there is any loss of the power of speech. As you hear, he answers slowly, prolongs his syllables, and has a little scanning speech. You also observe a tremulousness of the lips. He speaks slowly, because he thinks slowly. He states that he never stammered before, but has noticed lately that he does. Giving him a newspaper to read, he succeeds very well. This shows that the slowness of speech is due more to loss of

mental power than to loss of power over the organs of speech. When he has the words before him, so that he does not have to think them, he speaks much more freely than when he has to think the words. This is then a case in which there are undoubtedly some symptoms of the disease of which I have given you some account. The question which I want especially to bring before you, relates to the diagnosis. The diagnosis of a fully formed case of general paresis is very simple and easy, but to diagnose the disease early, at the only time when you can possibly hope to do good by treatment, and at the time when you are especially pressed for an opinion as to the future, is sometimes extremely difficult and very uncertain. Where there is delirium of grandeur, with failure of mental power, especially loss of memory, with some failure of motor power, with disorder of the speech, of course the man who runs can make the diagnosis.

There are three affections which are liable to be confounded: general paralysis, cerebral syphilis, and chronic alcoholism. In addition to these you will sometimes, particularly in the early stages, be asked to decide whether or not there is anything at all the matter. This is especially true in cases in law. Let me cite an illustrative case. A man whom I believe had been a banker, and who was in good circumstances, came to a large city and took rooms at a hotel. Soon afterwards he brought home with him one day, three women of the town and wanted to take them to his room, but was prevented by the landlord. A few days later numerous wagons began to come to the hotel, bringing pianos which the man had bought. The landlord, suspecting that something was wrong, telegraphed to his people, and in a short time marked symptoms of the disease developed. Whenever a man suddenly changes in disposition, suddenly becomes extravagant, or exceedingly irritable, or very lewd, or any other emotional symptoms develop suddenly, without obvious cause, you should be on your guard, and remember that the patient may have commencing general paralysis.

In our present patient it is somewhat embarrassing to decide whether he has this or some other affection. The delirium of grandeur is usually stated to be characteristic. But, as I have already said, it is not characteristic. It may occur in certain forms of chronic mania, and I know that it may appear in syphilis of the brain. There is, however, very little difficulty in diagnosing between the delirium of grandeur occurring in mania and that occurring in general paralysis. In the delirium of mania, the man, if he asserts a thing, acts it. Thus he declares that he has a strong right arm, and, acting upon that belief, knocks you down; the patient with general paralysis, will hold out his soft, flabby arm, and tell you that it wields the power of the universe, but he does not attempt to use it. The latter patient probably believes what he says; but he does not believe it in the same way that the former does; his acts and his belief do not correlate.

The delirium of grandeur of syphilis exactly simulates the delirium of grandeur of ordinary general paresis. Last spring, we had in this house a man who presented very closely the symptoms of general paresis. As the case is of interest in this connection, I shall briefly relate his history. R. G., age about thirty, came into the hospital suffering from partial dementia with distinct delirium of grandeur. He had, at the same time, headache which was worse at night; he had a clear history of specific disease. The delirium of grandeur took the form of belief in the possession of great wealth. He said that his relatives were immensely rich, that his uncle was worth millions, and would pay all his bills; he would give a million to the hospital and a million to the doctors for getting him well and out of it. There was distinct failure of memory and loss of power of fixing the attention. There was, however, no affection of speech and the power of locomotion was good. He was put upon the use of iodide of potassium in large doses for a time, then ptyalized, and then again iodized. Under this treatment, the symptoms gradually ameliorated, and he left the hospital in about two months apparently perfectly well, with the mind clear, the memory restored; he seemed capable of performing, as well as ever, his habitual duties of life.

This was a case in which delirium of grandeur existed in a man with a specific history, and in which a cure was effected seemingly by specific remedies. The fact that a man has had syphilis, is no proof that the disease from which he may be suffering is a result of the specific disease; but when a patient has a specific history and his symptoms disappear under the use of specific remedies, the evidence is pretty clear that the affection has been specific.

When delirium of grandeur is the only symptom the diagnosis can only be made out by attention to the history and by watching the case; oftentimes, an opinion must for a time be withheld. My own experience leads me to say that you should look unfavorably on a case in which, in addition to the delirium, there is loss of the power of speech. I do not remember to have ever seen alteration of speech associated early with mental failure or delirium of grandeur, in a case which I knew to be specific. A year or two ago, there was such a case in the hospital in which there was reason to suspect syphilis, but as the man remained under observation a short time only, we were unable to satisfy ourselves on this point. When you have the mental symptoms associated with disorder of speech, you may look upon the case as probably of the more serious disorder.

In regard to chronic alcoholism. In this condition the delirium of grandeur is very rarely present, but frequently there is some failure of speech and slight loss of power. I have never seen a case offering any difficulty, but it is possible that a diagnosis could only be made by learning the history and by watching. If you have a case simulating general paralysis directly due to chronic alcoholism, and you take that man off of his alcohol for one, two, or three months, he will certainly improve.

In some cases, and perhaps in the present, the diagnosis lies not so much between general paralysis and alcoholism or syphilis, as between general paralysis and disease at the base of the brain, affecting the organs of speech. I refer to glosso-labial paralysis. This is nothing more nor less than a chronic poliomyelitis, affecting the upper portion of the spinal cord, which we call the medulla. Glosso-labial paralysis is, in other words, a chronic muscular atrophy, affecting the tongue, muscles of deglutition, and the lips; those parts whose centres are in the medulla. In this disease there is no mental deterioration, because the upper brain is not affected. We must therefore decide, in the present case, whether there is any mental failure. He denies loss of memory or mental power, and shows some wit in answering my questions, but his wife states that there is a decided failure of memory and also that his emotional nature is changed, in so far that he worries a great deal (this was especially marked in the beginning of the case), although he has not become irritable or cross. She denies any change in his sexual relations. As I question him, you notice that there is a tendency to echo my words. Every now and then he repeats a sentence after me. This is a very curious mental tendency which we all have to some extent. When the mental power is weakened from any cause, this proneness to echo words is markedly increased, because, as the upper nerve-centres are enfeebled,

automatic action becomes less and less controlled. It is sometimes stated that this repeating is characteristic of the disease under consideration, but this is not so; it simply indicates that there is loss of mental power: that the upper centres are in a condition of exhaustion or depression from some cause, but it does not indicate any particular cause. There is, as you observe, a distinct loss of memory. He is unable to tell me what he read about a few minutes ago, without stopping to think; and there is a slowness of mental action which is almost characteristic.

There is a mental condition which sometimes exists in general paralysis, and which I think is present in this case. You will find in some cases of the disease that while there is no true delirium of grandeur, or even while the patient seems to be depressed, he is really very well contented. This man is in circumstances which would depress an ordinary man. He has always been industrious; has a wife and family dependent upon him; he is broken in business, and has had to quit work and come into a hospital; yet he appears not to be depressed, but very well satisfied with himself and his surroundings. His wife left him weeping, and unable to see how the family would get along. He was, if not triumphant in expectation or belief in his millions, placidly content.

I shall now test his sensation with the æsthesiometer. Loss of sensation is not always present in general paralysis of the insane, yet it has a certain value from a diagnostic point of view. If I find marked loss of sensibility, I shall add that to the heap of facts tending towards the diagnosis of general paralysis. Observe the tremulousness of the eyelids when he closes them. I can make out no distinct anæsthesia.

In advanced general paralysis the gait is distinct. This man can, however, walk pretty well. Frequently, the first thing noticed in reference to the gait is that the patient walks with difficulty where it is rough.

Q. Have you noticed that you cannot walk as well as you used to on cobble-stones?

Ans. Yes; but there is a reason for that.

Q. Well, what is the reason?

Ans. I have got corns.

This man tells us that he has had some increased difficulty, which he attributes to the presence of corns, but on close questioning I find that he has always had corns and that his difficulty of walking in rough places is recent.

Let me sum up the points that we have made out; from the statement of his wife and from our own observation, we learn that there is a distinct loss of memory, there is a marked slowing of mental action, the man thinks very slowly and talks slowly and uncertainly; there is no headache, we also find disturbances in the emotional sphere; the man, especially early in the attack, was disposed to worry a great deal, and now he does not worry as he ought to do if himself; in the motor sphere, we find that the speech is markedly affected, there is reason to believe that walking is affected, in so far as rough places are concerned. Taking these things into consideration, it seems probable to me that this man has either a specific brain trouble, or the first stage of general paralysis. I do not think that it is due to specific disease, because as I have already stated, in my experience, disorder of speech connected with failure of mental power is exceedingly rare in syphilis. In the hundreds of cases of cerebral syphilis which I have seen in this and other hospitals, I have never early in a case seen the speech affected when the upper brain was attacked. Syphilis attacks either the upper brain by itself or the lower brain by itself, rarely affecting both at the same time. In general palsy, all portions of the brain are affected.

The diagnosis, that this man has not syphilis, is confirmed by the result of a therapeutic trial. We have found that iodide of potassium, in ten grain doses, rapidly produces symptoms of iodism.

I shall devote the few remaining minutes of the hour to a brief consideration of the pathology of this disease. The pathology of general paralysis is a chronic inflammation of the whole material of the brain. As you know, the vessels of the brain run through what are called perivascular spaces. These are lymph spaces and are filled with a transparent fluid. This disease probably begins in these lymph channels, and perhaps at the same time in the surrounding neuroglia. Under the microscope it is found that a rapid formation of cells occurs in these channels and they soon become filled with lymphatic elements. At the same time nuclei appear in the cells of the neuroglia outside of the lymph spaces, and there is a rapid multiplication of cells; changes which are allied to those of sclerosis. This same series of changes takes place in certain forms of cerebral syphilis. I have very carefully studied these changes in syphilis with the microscope, but I can discover no difference between the changes in syphilis and those in general paralysis. The only pathological difference that is diagnostic is that in syphilis the disease is localized; it affects either the gray matter or the white matter alone; in general paralysis both are affected. In general syphilis involving the cortex of the brain there will be mental failure without headache (if there is headache, there is meningitis added to the cortical disease), without failure of motor power, without anything else except progressive mental failure; the man becomes apathetic, sometimes more or less excitable, but his mind, as it were, gradually oozes away. If a slice were made of such a brain, the gray matter would be found to be entirely sclerosed. The appearances in syphilis and general paralysis are similar, but the results of treatment are very different; the diagnosis is therefore of the greatest importance. Where in any case, you are in doubt, you should of course give the patient the benefit of the doubt and try the effect of specific remedies. The treatment of general paralysis is without avail.

ACTION OF PULSATILLA IN THE TREATMENT OF GONORRHŒAL EPIDIDYMITIS.

BY F. R. STURGIS, M.D.,

PROFESSOR OF DISEASES OF THE GENITO-URINARY SYSTEM AND OF VENEREAL DISEASES IN THE N. Y. POST-GRADUATE MEDICAL SCHOOL; ONE OF THE VISITING SURGEONS TO CHARITY HOSPITAL.

(*Read before the Materia Medica Society of New York City, December 28, 1882.*)

A FEW years since I published in the *Medical Brief* a short paper with the report of four cases on the action of *Pulsatilla nigricans* in the treatment of gonorrhœal epididymitis, where the drug seemed to me of benefit. Others of my colleagues had used the drug with varying success, but I believe the majority rather coincided with the opinion of Dr. E. L. Keyes, to wit, "It" (pulsatilla) "has failed in my hands, employed in both ways" (*i. e.*, "from one-tenth minim, often repeated, up to one drop three times a day") "either to check the pain or modify the course of the malady." Coming from the source it did, this statement led me to reflect that perhaps my desire to relieve pain had interfered with a calm judgment of facts. I therefore determined to extend my experience of pulsa-

tilla in this class of cases, and the result of this experience is what I shall now present.

The preparation of the drug used in all my cases was the homœopathic tincture, the so-called mother tincture, and my object in so doing was to obtain a preparation of uniform strength. It is made in the proportion of one part of the fresh plant to six parts of alcohol. Although the species used by me was the P. nigricans, other varieties of the pulsatilla (the P. pratensis and the P. nutalliana) are, according to Hughes, of equal value, as they all contain the active principle, anemonin. Introduced to professional notice by Baron Stoerck for a variety of diseases—cataract, amaurosis, secondary syphilis, etc., it speedily fell into disrepute, or rather disuse, perhaps because the preparations used were of variable strength. I was led to employ the drug in the hope of finding it useful in allaying the exquisite pain attendant upon this variety of gonorrhœal complication, and certainly, in the result shown in the cases reported, I believe my expectation has been realized.

CASE I.—G. J., æt. 27, was admitted to the Charity Hospital November 17, 1880, with a gonorrhœa of somewhat over a week's duration. His previous venereal accidents were gonorrhœa, dating back seven years, without complications, and syphilis contracted six years before.

One week after the commencement of his present attack, the left testicle became swollen and exceedingly painful. This was shortly before his entrance into the hospital. Two leeches were applied on the 18th inst. to the external abdominal ring, and the testicle was wrapped up in a tobacco poultice. This treatment was continued for several days without benefit, the testicle still continuing swollen and painful. On December 1st he was ordered to get out of bed and take two minims tinct. pulsatillæ every hour. Three days later, December 4th, the record showed that there was very little pain, except at the globus major, and the testicle had diminished very much in size. The pulsatilla was continued until the 6th inst., when it was discontinued, as there was no further pain. The urethral discharge was treated by injections, and on December 29th he was discharged well, no pain having returned meanwhile in the testicle.

CASE II.—P. K., æt. 42, entered the hospital December 6, 1880, with a clap of twelve days' duration. His previous venereal history was two attacks of gonorrhœa, one dating back twelve years, the other two. The first attack was complicated with a suppurating bubo in the right groin, the second with two swelled testicles. Ever since this last attack he has had a gleet. On November 24, 1880, the right testicle began to swell, accompanied by a dragging sensation in the scrotum, which was relieved by an elevated position. Has had (and now has) a slight urethral discharge, but no acute clap.

On entrance into hospital, December 6, 1880, inspection showed a swollen and inflamed scrotum. The right testicle was enlarged, and tender upon handling, the pain extending up the cord. Usually the pain is of a dragging nature, except when the testicle is squeezed, when it becomes acute and produces nausea, extending up into the inguinal canal and into the abdomen. Nothing was done for him until the 10th, when, as the symptoms remained as acute as at first, two minims of tinctura pulsatillæ were administered every hour, and he was not allowed to remain in bed.

December 12.—Pain in testis is decidedly less.

14th.—Can bear quite rough handling. Epididymis still large and hard, but less so than on December 10th.

16th.—Pulsatilla stopped, as the pain has gone. To use injections for the urethral discharge.

21st.—Discharge disappeared. Reports some return of pain in the testis. As this organ shows no signs of inflammation and admits of free handling, nothing was done.

28th.—Pain has entirely gone.

Jan. 18, 1881.—No return of pain in testis, which has resumed its normal size. Slight induration left at globus minor. Discharged well.

CASE III.—D. S., aged 24, entered hospital December 10, 1880. No previous venereal accidents. On December 1, 1880, he first noticed an abundant muco-purulent discharge from the urethra, with dysuria. December 8, his left testicle swelled and was very painful. This pain extended to the small of the back. The discharge diminished as the pain came on.

Examination revealed the following condition of things. Slight urethritis. Left epididymis swollen and very painful on handling. Scrotum inflamed. Spermatic cord thickened and painful. Tobacco poultice applied to the testicle, which on the 12th inst. was changed to one of flaxseed.

Dec. 15.—On the 13th inst., as the condition of the testicle had not improved, he was told to use two minims of the tincture of pulsatilla every four hours. No local application was made, and patient was directed to keep out of bed. To-day the pain in the testicle much relieved.

29th.—Pulsatilla stopped on the 18th, as the pain had entirely ceased. The testis is as large as before, but painless. Discharged improved.

CASE IV.—T. D., aged 25, entered hospital January 18, 1881. No previous venereal accidents. On December 28, 1880, four days after coitus, his clap began. On January 5, 1881, his right testicle became very much swollen and painful. On January 14, the urethritis ceased.

Jan. 18.—No discharge from the urethra. The right testicle is swollen, red, and moderately painful on pressure. The swelling extends up the cord. Was directed to take pulsatilla tincture, one minim every hour, and to remain out of bed.

25th.—Pain was not relieved for four days after commencing medicine. Now all the symptoms recorded at entrance have disappeared. The epididymis is slightly enlarged, otherwise the testicle is normal. Discharged well.

CASE V.—N. M., entered the hospital January 18, 1881. Previous venereal accidents were gonorrhœa in 1873, and chancres in 1875. No syphilitic history. On December 31, 1880, three days after coitus, he discovered a muco-purulent discharge from the urethra without chordee or dysuria. On

January 13, 1881, his left testicle became swollen and painful.

Jan. 18.—Examination showed the left epididymis swollen and extremely tender. Body of testis normal. Scrotum slightly inflamed; cord not implicated. Muco-purulent discharge still present, but without dysuria or chordee. To take tinctura pulsatillæ, one minim every hour, and to remain out of bed.

25th.—Twenty-four hours after treatment was commenced the pain in the testicle was relieved. To-day no pain is manifested in handling the testis. The inflammation of the scrotum has subsided, and the enlargement of the epididymis is materially less. Urethritis unchanged. Discharged at his request.

Case VI.—H. S., æt. 26, entered the hospital February 28, 1881. Previous venereal history is three attacks of gonorrhœa without complications. Nothing else until present attack, which was first seen January 30, 1881, five days after coitus, in the shape of a slight urethral discharge, accompanied by ardor urinæ. The discharge was at no time very abundant. On February 24, 1881, patient felt pain in the testis and cord on the right side, and discovered that the organ was swollen. The pain and swelling have increased up to the present (28th). The scrotum became inflamed on the 26th instant. On the 24th the discharge diminished in quantity, and at the present is confined to two or three drops in the morning.

Feb. 28.—Examination shows the whole epididymis of the right testicle acutely inflamed, accompanied with effusion into the tunica vaginalis. It is very painful and swollen to three times its normal size. The scrotum is reddened and the temperature of the part is elevated. He was ordered to take tinctura pulsatillæ, one minim every hour, and to remain out of bed.

March 1.—Complains of increased pain in testicle. Ordered to bed: pulsatilla continued.

4th.—Pain still worse, and as it was evident that the pulsatilla was not doing good, its use was abandoned and the patient was put upon other treatment.

These cases include all the gonorrhœal affections of the testis treated by pulsatilla during the four months of November and December, 1880, and January and February, 1881, in the wards of the Third Venereal Division of Charity Hospital, and the histories are to me instructive. Here are six cases, all acute, in three of which one minim of the tincture is given every hour; in two cases two minims are given every hour, and in one two minims are administered every four hours. In one case relief is obtained in twenty-four hours; in two cases in two days; in one case in three days; in one case in four days, and in one case there is a total failure. In one case, No. 3, where two minims were given every four hours, relief was as speedy as in No. 2, where the same dose of the medicine was given every hour, and more speedy than in No. 1. In No. 6 there was no success, and I regret that, before changing the treatment, I did not try smaller doses of the medicine, which are said to be effective when larger doses fail. The length of treatment varied from four to seven days, an average of about six days, but relief began long before that time in all the cases which were benefited.

The date of the disease at which treatment was begun, varies from thirteen to twenty-nine days from the first appearance of the clap, and from the result it would not appear that the element of time exercised much influence upon the cure.

In the five cases in which the symptoms were relieved, no relapse took place, although during and after the treatment the patients were not allowed to remain in bed.

Two points are worthy of special mention in giving this drug for the relief of gonorrhœal epididymitis: One is that its action is confined to the relief of the pain, and seems to have no influence in reducing the size of the inflamed testicle; the second, is that the relief, if any is to be afforded, will take place within forty-eight hours after the administration of the drug. I certainly should not continue its use beyond three days if no benefit ensued within that time.

I offer this fragmentary contribution, with many apologies for its imperfections, with the less hesitancy, because I think in this drug we have another and a fairly good means of combating a painful and distressing affection.

16 West Thirty-second Street, New York City.

A CASE OF HÆMOPHILIA: VARIOUS HEMORRHAGES CONTINUING FOR FIFTEEN DAYS.

By E. F. TIEDEMANN, M.D.,
of O'Fallon, Ill.

On September 3d, at 8 A. M., I was called to see Eva T., a domestic, aged 18, on account of very profuse epistaxis. She told me that on the day previous she had noticed, by means of a mirror, blood trickling down her throat; she had also bled from the mouth, but the bleeding was not severe till 6 A. M. that morning, when it commenced very profusely from the anterior nares. She thought she had lost a wash-basin full of blood, and her blanched and feeble appearance confirmed her statement. Examining her mouth, I found slight oozing from five decaying teeth; the last molar and the second bicuspid on the right side of the lower jaw; the first molar on the left side; and the first and second molars of the left upper maxilla. There was no hemorrhage from the posterior nares. On the back of her left hand was a large ecchymosis, about two inches in diameter, and of a blue color; on her right forearm were two smaller spots, of a reddish hue. On her arms I found numerous spots of purpura hemorrhagica, especially around the elbows. She told me that there were many large and small spots on her lower extremities, and she was very certain she had received no injuries which might have caused the ecchymoses.

After the introduction of some pledgets of cotton soaked in a solution of iron perchloride into the anterior nares, the bleeding apparently ceased, and the oozing from the decayed teeth stopped of itself.

I was told that the girl had always had frequently recurring hemorrhages from the nose; on one occasion, about two years ago, the bleeding was so severe that a physician was called in. Whenever she bled profusely from the nose, numerous blue and red spots appeared on her body. She had also suffered much from menorrhagia, her courses sometimes lasting two or three weeks. Still, it was not known that she had the hemorrhagic diathesis.

I was again called at 11.30. The hemorrhage had returned from the posterior nares and the decayed teeth. I injected both nasal cavities with a dilute solution of perchloride of iron, and touched the bleeding spots in the mouth with pure liquor ferri perchloridi, and administered gallic acid, ergot, and opium in full doses. Bleeding from the posterior nares stopped, but continued anteriorly; I now plugged the anterior nares with cotton moistened with the iron solution, but the blood continued to ooze through and by the side of the plugs like water. Finally it stopped when I used a powder of tannic acid, alum, and gum arabic on strips of lint, pushing them in very tightly. The blood looked thin, and was evidently lacking the factors of coagulation, clotting but very feebly.

Saw the girl again at 5 P. M.; the teeth mentioned and their gums were bleeding afresh.

At 8 P. M. she was again bleeding from the posterior nares, blood trickling down the pharynx continually. I now determined to plug the posterior nares, and called on Dr. H. T. Bechtold for aid. We plugged both posterior nares with pieces of sponge moistened with the iron solution. During the procedure hemorrhage was very severe, and vomiting of black blood occurred several times. We also plugged the anterior nares, but blood continued to ooze, and the plugging had to be repeated several times. The bleeding finally ceased when we used pieces of sponge and smeared their free sides with the powder mentioned, which produced sticky clots. The bleeding had changed from one nostril to the other, sometimes coming from both at once.

When the hemorrhage from the nose had ceased, bleeding from the right last molar of the lower jaw and the gum surrounding the second molar commenced, and continued steadily. Failing to check it, we called to our assistance Dr. Mace, a dental surgeon, who finally controlled it by means of a large pledget of cotton and iron, placed so as to exert pressure. It was now 12 o'clock at night. I remained at the patient's house.

4th.—During the night patient bled from anterior nares, necessitating renewed plugging; oozing from the posterior nares and the last molar set in at 3 A. M., and continued all day. I administered a brisk purgative of epsom salts, which was followed by large, black evacuations of a tarry consistency. Œdema of uvula and soft palate, due to the pressure and irritation of the plugs, occurred and obstructed respiration considerably. As the plugs did not prevent bleeding, I removed them at 6 P. M. Profuse hemorrhage followed. Gave 15 grains quinine in solution; it was vomited at once; administered 5 grains hypodermically, with no result. In consultation with Dr. Bechtold, we injected the nose with vinegar, iron, ice water, introduced pieces of ice far up into the nose; applied ice to back of neck and to nose externally, had her hands elevated, etc., without the least effect. Dr. Bechtold insufflated powdered Monsel's salts by means of a Politzer bag and a glass tube into the nose; this was effectual for a while by producing firm clots both behind and in front. Unfortunately vomiting set in and the clots were dislodged. We insufflated again, but hemorrhage continued. We now determined to cease all efforts at controlling hemorrhage, as nothing was accomplished thereby. I remained at the house during the night. Some clots had formed, and by smearing Monsel's salts over the anterior nares bleeding was checked in front. Slight oozing from behind and from the teeth during the night. Vomiting was checked by morphia hypodermically; beef-tea and milk were given freely. Patient very weak; pulse 120, skin cool.

5th.—Slight oozing from posterior nares continues. *Hæmaturia* has set in; color of urine varies between blood-red and brownish-black.

6th.—Oozing from anterior and posterior nares; hæmaturia continues unabated. Gave fl. extr. ergot ♏xx every hour; vomiting of clotted blood after third dose; dilute sulphuric acid is not borne. Three black, tarry evacuations.

7th.—Hæmaturia and oozing from anterior and posterior nares continue. New ecchymoses are forming; blood is pale-red, watery; patient very weak; pulse 96 in the morning, rises to 108–120 in the evening. Milk is given every hour. We resumed the administration of ergot. Patient is very deaf and complains of pain in the ears, especially the left, caused probably by extension of inflammation of pharynx. Suffers much from headache. Drinks several quarts of milk during the day. Very fetid smell from mouth.

8th.—Removed clots from nose and washed it out with tepid water. Hemorrhage ceased from nose entirely, but hæmaturia still continues.

At 6 P. M., patient had a chill followed by fever and severe headache; vomiting occurred; pulse 120, and very feeble. The nose was again syringed with water, and quinine administered during the night. Patient was very restless and slept but little.

9th.—*Bleeding from the genitals* appeared this morning; no examination made, but I suppose the blood came from the uterus; ascertained that she had stopped menstruating only three days before the first hemorrhage occurred, the flow having lasted seven days. Hæmaturia has ceased; headache and deafness continue; temperature 101°; pulse 108; tongue dry at tip; very bad odor from mouth and nose. Frequent washings, and ten grains of quinia sulphate every four hours. Patient is exceedingly weak; appetite gone; bilious vomiting in afternoon.

10th and 11th.—Patient is improving; no fever; pulse, 92, 100; bleeding from genitals continues moderately. Tr. ferri chloridi given in large doses.

12th.—Hemorrhage from genitals has ceased, but *hæmaturia* has returned; urine almost black.

13th.—Pulse, 82; appetite very good; hæmaturia

continues. Pain in ears is less, and hearing improved.

Steady improvement followed, but the urine did not become clear till September 17th.

Counting September 2d, when she first noticed blood in her throat, as the beginning of the attack, it is seen that she bled more or less every day for fifteen days. Bleeding continued till it seemed that she was almost drained of blood. She had evidently possessed more than the average amount of blood, and her organism must have made blood very rapidly. She was up and about ten days after bleeding ceased, and in a month she was nearly as plethoric and strong as before. It must be added that she has a very large appetite and digestive capacity, eating as much as two other persons.

Eva T. is of very stout, heavy build, with a strong bony and muscular development; has light-brown hair and blue eyes, and a fair skin. Her mother was of Irish birth; her father is a German. Her family history is very bad; her mother died of consumption; the father is given to excessive drinking. She has two sisters and a brother; the oldest girl has epilepsy in a very severe form; both other children seem to be of the hemorrhagic diathesis, for they, too, bleed frequently and violently from the nose. I have, unfortunately, not been able to ascertain whether the mother was a bleeder or not, but it seems probable, as the father is certainly free from the disease.

Eva T. states that she has had attacks of bleeding from the nose as long as she can remember, and sometimes even slight cuts bled for an hour or two. She can always tell when an attack is impending by a feeling of fulness or distention, and throbbing, especially in her head. Her face is then flushed, she is excited, and yet appears to be in a dull, bewildered condition. This same appearance is noticed during her menstrual periods. She suffers much from toothache, but there is no history of rheumatism.

A remarkable fact is that when bleeding was arrested at one point it broke forth at another; thus, epistaxis was followed by bleeding from the mouth,; when this stopped, epistaxis returned, to be followed by hæmaturia; when this ceased, metrorrhagia appeared, and this was followed by a recurrence of hæmaturia.

I am not certain whether there was bleeding from the intestinal tract or not; but I thought the amount of blood vomited and passed at stool was more than could be accounted for by the quantity of blood that was swallowed.

The treatment adopted was without the least avail; gallic acid and ergot in full doses was fruitless; free purgation, advised by Wachsmuth, did not end the attack; neither did the small and often repeated doses of ergot given by him influence the disease. Quinine in large doses, recommended by Verneuil, had no effect; plugging the nares and the use of styptics was not only ineffectual and productive of much pain and discomfort, but I think did harm.

I have advised the girl to be moderate in her diet, and to take epsom salts freely when she feels hemorrhage is impending. Should this be useless, I would limit myself to the use of continued purgation by means of salines; the administration of gallic acid and ergot, and sulphuric acid; and the withholding of fluids as much as possible. Paradoxical as it may seem, I think free venesection might be useful, by rapidly lowering blood pressure.

Since the patient has passed through this formidable attack, she has twice bled from the nose; but the loss of blood was not great. The case is, I think, interesting not only owing to the rarity of the disease, but on account of the length of the attack, and the many various forms of hemorrhage which occurred.

HOSPITAL NOTES.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

Service of JOHN ASHHURST, JR., M.D.

SYPHILIS OF THE HAND.

(Reported by GEORGE WOODRUFF JOHNSTON, M.D., Resident Surgeon).

MICHAEL T., aged twenty-five years, a miner, was admitted to the surgical wards of the University Hospital on November 7, 1882, with the following history: About thirteen weeks before admission he was bitten upon the hand by a young man, a fellow workman, who was said to be afflicted with the "bad disease." Two sores resulted from this injury, one of which, at the time of the patient's admission into the hospital, presented the peculiarities of a typical Hunterian or hard chancre, while the other, having been scratched and otherwise tampered with, had taken upon itself a phagedenic form, and threatened to destroy the entire finger. Under the influence of appropriate treatment, the sores quickly lost their characteristic appearance, and two weeks later presented the following aspect: Upon the distal phalanx of the ring finger of the right hand was seen an ulcer, nearly circular in shape, and about one-half an inch in its greatest diameter. The edges of this sore, which were rather lower than its centre, were sharply defined, and to the touch seemed hard and infiltrated, while a thin blue line of new skin marked the boundary of the central healthy granulations. The middle finger, the only other part of the hand bitten, suffered more severely, and even at the time spoken of, although the healing process had gone on with remarkable rapidity, it was much distorted, and showed the marks of grave inflammatory action. The distal end seemed as though it had suffered a downward and backward dislocation upon the middle phalanx, and though doubts had been entertained as to the possibility of saving it, the joint in all probability having been opened, yet now it seemed as if nothing but the nail would be lost. Already the palmar surface of the finger was healed, and the dorsal presented a most healthy aspect.

The only other lesions noted upon the patient were a chain of enlarged lymphatic glands, buboes, extending from the wrist of the affected hand well into the axilla, first noticed four weeks after the infliction of the bite and persisting up to the present time, and an eruption which presented on the anterior aspect of the arm, just within the bend of the elbow, the characteristics of the papulo-squamous syphiloderm. One other lesion, an erythematous condition of the mucous membrane of the throat, must not, however, be forgotten.

The treatment pursued in this case consisted in the internal administration of mercury, and the external

use of the ointment of iodoform. The mercury was given in the form of the protiodide, in one-quarter grain doses, guarded by opium to prevent its purging. Iodoform ointment in the strength of fifteen grains to the ounce of vaseline, spread upon lint, was applied once daily to the fingers after their having been thoroughly cleansed, not because it has any specific action upon syphilitic lesions, but since it makes at once a clean and disinfectant dressing when applied to any ulcerating surface.

MEDICAL PROGRESS.

ANEURISM ABOUT THE GALL-BLADDER.—Instances of death due to hemorrhage from aneurisms on the smaller branches of the cœliac axis are certainly not very common, but PROF. HALLA recently showed an example of such a condition before the German Medical Society in Prague (*Wiener Med. Wochenschrift*, No. 5). The patient from whom the specimen was taken had suffered during life from melæna. In the œsophagus, stomach, and intestines, blood was found, which came from the duodenum, in which, at a distance of two fingers' breadth from the pylorus, an ulcer leading into the gall-bladder was to be seen blocked up with a blood-clot. The gall-bladder contained about twelve stones, and in its wall there was a small aneurism of the right hepatic artery, which had burst, and apparently led to death. A second small aneurism was also found projecting into the gall-bladder, and depending from a branch of the gastro-duodenal artery. The explanation given by Halla was that gall-stones had set up ulceration and arteritis, and so led to the formation of aneurisms, analogous to those occurring in the walls of pulmonary cavities. The binding together of the gall-bladder and the duodenum was regarded in a similar light.—*Medical Times and Gazette*, February 17, 1883.

CHOLECYSTOTOMY.—At the meeting of the Birmingham and Midland Counties Branch, held January 26, 1883, MR. LAWSON TAIT showed a patient upon whom he had performed cholecystotomy in October last, and exhibited the sixteen gall-stones which he had removed. The patient had been suffering from the usual symptoms of distention of the gall-bladder, these being, as usual, intermittent. During their existence a movable tumor over the right kidney could be felt. There seemed to be, as far as Mr. Tait could determine, a good deal of misunderstanding about the symptoms of gall-stone and its cause. As long as the stones were loose in the bladder they gave rise to little or no uneasiness, and this explained the frequent discovery of numerous gall-stones in the gall-bladder, on post-mortem examination, although they had caused no suffering during life. But if a calculus gets into the neck of the bladder and then becomes impacted, the mucous secretion of the inner coat of the bladder collecting behind the stone, distends the cyst, and its spasmodic efforts to expel its contents become the cause of agonizing pain. Till the calculus passes as far as the common duct there is no jaundice. Cholecystotomy is a very easy operation, and considering that it was originally proposed, in 1743, by Jean Louis Petat (*Mémoirés de l'Académie de Chirurgie*, tome i. p. 155), it is marvellous that no one ever attempted it until three years ago.—*British Medical Journal*, February 17, 1883.

THE POISONOUS PRINCIPLE OF EDIBLE MUSHROOMS.—M. DUPETIT recently read a note before the Académie des Sciences, in which he stated that the poisonous principle of mushrooms was insoluble in ether, chloroform, sulphide of carbon, ethylic and methylic alcohol. When in solution in water it is precipitated almost completely by alcohol, tannin, acetate or hydrate of lead, and can be separated with a precipitate of phosphate of lime. These are the general characteristics of soluble ferments rather than of alkaloids. In addition the temperature of 100° C. completely destroys its virulence; so when mushrooms are well cooked they lose their poisonous properties.

Further experiments have shown him that many of the phanerogamia contain an analogous principle.—*Journ. de Méd. de Paris*, February 10, 1883.

NEPHRO-LITHOTOMY IN A CASE OF ISCHURIA.—This case is reported by DR. THELEN in the *Centralbl. für Chir.*, No. 12, 1882. The patient, aged 27, who had been suffering from spasmodic stricture, became the subject, during an attempt at dilatation of the urethra, of an accidental fracture of an elastic catheter, a portion of which passed into the bladder. Violent inflammation was excited in the bladder, and an abscess formed in the left iliac fossa. The abscess, opened with antiseptic precautions, was behind the peritoneum and connected with the pelvis of the kidney. It was almost entirely healed within five weeks, when suddenly rigors and suppression of urine occurred. The catheter brought away only mucus and a small calculus. Destruction of the left kidney and closure of the right ureter by a calculus were diagnosed. Dr. Bardenheuer, as the only means of saving the patient's life, determined to remove the calculus, for which purpose an incision was made, extending from the eleventh rib to the crest of the ilium. In order to reach the pelvis of the kidney and the ureter, it was necessary to detach the anterior border of the kidney from its cushion of fat, by the hand. The instant that the stone was felt in the hilus it slipped back into the pelvis of the kidney, and the flow of urine through the ureter showed that the passage between the bladder and the kidney was free. In order to maintain this favorable position of the organ as long as possible, the kidney was drawn backwards and outwards, so that the pelvis was visible at the bottom of the wound. An incision was made into the commencement of the ureter; a calculus about the size of a bean and four smaller pieces were removed, and the operation was concluded by sutures in the edges of the incision in the ureter. The urine, however, passed not through the ureter, but by the wound. Four days later, Dr. Bardenheuer determined (as the urine continued to trickle out) to divide the ureter, and to fix the upper end in the wound. One month after the operation, the urine passed through this artificial ureter; the wound was uniting at parts where the urine did not come into contact; the patient, though feeble, was recovering.—*London Medical Record*, February 15, 1883.

PORRO'S OPERATION.—PROF. VON WEBER reports a case of Porro's operation in the *Allgemeine Wiener Med. Zeit.*, 1883, Nos. 2 and 3, in which he performed Porro's operation. The mother died three days after the operation; two male infants were extracted alive: of these one died two weeks later from general atrophy, while the other is still alive and vigorous.

PILOCARPINE IN PUERPERAL ECLAMPSIA.—P. CANTILENA reports a case in which severe eclampsia set in immediately after delivery in a woman, in whom albuminuria had been present during pregnancy. Pilocarpine was regularly administered in doses of two decigrammes two or three times daily, together with drastics, and in twenty-four hours the woman was out of danger, and a perfect cure resulted.—*Centralb. f. klin. Med.*, February 3, 1883.

The Symptoms of Cancer of the Pancreas.—Dr. Alois Biach gives the following tabulation of the symptoms generally met with in pancreatic cancer, based upon a study of seventy-three cases: 1. Pain; 2, various dyspeptic disturbances; 3, pancreatic salivation; 4, pancreatic diarrhœa; 5, fatty diarrhœa; 6, the so-called "lipuria"; 7, the presence of a tumor in the epigastrium, which occasionally pulsates; 8, bronze coloration of the skin in occasional cases.

No one of these symptoms, however, can be regarded as sufficient for making a positive diagnosis.—*Wiener Med. Presse*, February 11, 1883.

Syphilitic Lesions of the Intestines.—At the meeting of the Medical Society of Vienna on January 19, Prof. Kundrat related the results of investigations made by Mrazek and himself on the alimentary tract of individuals affected with syphilis. It has been said that syphilitic disease of the intestines is very rare in the adult, but more frequent in the hereditary form of the affection. The proportion of five in forty, which was the average ascertained by Birch-Hirschfeld, is regarded by Kundrat as too high. When still-born children, already in a state of decomposition, were taken into account, Kundrat found only nine cases of intestinal disease out of a total of two hundred specimens of syphilitic children. The disease of the alimentary tract was never found alone. There were always morbid changes in other organs. The small bowel was affected eight times, the large bowel twice. Generally, the whole of the small intestine was diseased, though the stress of the mischief fell on the jejunum. Two types of disease were recognized, one more or less limited to the lymphoid structures, the other irregularly disseminated along the intestines. In addition to signs of catarrhal inflammation, there was hyperplasia leading to the formation of nodules, some as large as a hempseed. The microscopical characters were like those found in other early syphilitic growths. It was noted also that the contents of the bowels were thickened, the meconium being tenacious and sticking to the wall of the intestine. The peritoneum showed alterations in the form of inflammatory products of various sorts and a small-celled infiltration around the vessels. In two instances there were perforations of the gut and purulent peritonitis. It would, therefore, seem that such perforations can occur during intra-uterine life.—*Med. Times and Gazette*, Feb. 17, 1883.

The Contagion of Measles.—Dr. A. Beclère has made a careful study of the conditions attending the contagion of measles, of which we select his more important conclusions.

Rubeola is contagious from the commencement of the period of invasion to the end of the stage of eruption, a period extending through from eight to ten days. The contagious principle is contained in the secretion of the respiratory mucous membrane, and it still remains to be proved, that it has anything to do with the cutaneous desquamation. Although this contagion is diffusible, it is so only to a slight extent, and soon loses its active properties, and does not remain in the rooms occupied by the sick. The period of incubation lasts from thirteen to fifteen days; no immunity is conferred by the presence of any other eruptive disease. —*Gaz. Méd. de Paris*, February 17, 1883.

Resection of the Pylorus.—This operation (*Gazz. Med. Ital.*, Nov. 11, 1882) was performed by Prof. Bigi, in the Civil Hospital of Perugia, on a woman, aged 38. Cancer of the pylorus was diagnosed by Prof. Riva. The patient was much exhausted, and for some days had taken food only by the rectum. The operation was performed with antiseptic precautions, but the spray was not used. The abdominal parietes were incised to the right of the middle line; the tumor was exposed and drawn forward, with a good part of the stomach and duodenum, and was removed. Thirteen ligatures were applied, and, by a special suture, the stomach was reunited to the duodenum. Before commencing the operation, a hypodermic injection of morphia was given; the administration of chloroform was begun, but had to be suspended from the increasing debility of the heart's action. The operation lasted two and a half hours, and the patient bore it well. The temperature for a few hours in the evening reached 38.3° C. (nearly 101° F.). For the next three days (when the case was reported) it was normal, and all went well, giving every hope of a speedy cure.—*London Medical Record*, February 15, 1883.

Purulent Inoculation in the Treatment of Granulations of the Conjunctiva.—M. T. Terrier contributes a paper on this subject, in which he states that purulent inoculation is a valuable method for treating old conjunctival granulations with pannus. This method is indicated when the pannus is complete or thick, while it is contraindicated when the pannus is thin or incomplete. The pus derived from the purulent conjunctivitis of the new-born is most suitable for inoculation, though it is not inadmissable to employ gonorrhœal pus. The ophthalmia, so produced, should not be aborted, but treated methodically so as to avoid accidents to the cornea.

In order to complete the cure it is frequently necessary to cauterize the conjunctiva with sulphate of copper, nitrate of silver, or insufflations of calomel.—*Rev. de Chirurgie*, February 10, 1883.

The Diagnostic Value of the Bacillus Tuberculosis.—Prof. J. Dreschfeld thinks that from his own observations he is justified in saying that, though the bacilli in the sputum are of the greatest diagnostic importance in pulmonary phthisis, and though they occur in cases where there are as yet no physical symptoms whatever, we are not as yet justified in making the prognosis dependent either on their quantity or their fully developed state as found in the sputa.—*Brit. Med. Journ.*, February 17, 1883.

A New Galactagogue.—According to Dr. Anderson, nursing women in Jamaica are accustomed to drink an infusion of the leaves of *Gossyphium barbadensis*. Six or eight leaves are sufficient to make a cupful of this infusion which, when sweetened with sugar, has a very pleasant taste, may be taken to the extent of four or five teacupfuls in the day without inconvenience, and invariably stimulates the flow of milk.—*Gaz. Méd. de Paris*, February 17, 1883.

Milk Diet in Graves' Disease.—Dr. Schnaubert, in Botkin's *Ejenedeln. Klin. Gaz.*, 1882, No. 13, speaks very favorably of the value of exclusive milk diet in cases of exophthalmic goitre. In one of his patients, three weeks' treatment by milk restored digestion and general health, and so greatly improved all symptoms that some weeks later the patient left the hospital relatively sound, and remained so nearly two years. At this time, she returned with highly developed signs of the disease, and though the milk treatment again greatly relieved the patient's condition, she soon died. The necropsy showed hyperplasia in the cervical sympathetic ganglia, pigmentation of roots of the cervical nerves, and cerebro-spinal hyperæmia.—*London Medical Record*, February 15, 1883.

Thyroidectomy.—M. Delens read before the Société de Chirurgie a report of a case by Dr. Beaure-

GARD, of Havre, of a man aged 28 years, who suffered from a cyst of the thyroid, of the size of a large orange, which interfered with both respiration and voice. Aspiration was practised and some blood only removed. The tumor was surrounded by an elastic ligature, and on the third day was partially separated: on the fourth day hemorrhage necessitated the application of an écraseur and the removal of the tumor. In fifteen days the wound was completely cicatrized.—*Revue de Thérapeutique*, February 15, 1883.

INTESTINAL OBSTRUCTION CURED BY ENTERO-PUNCTURE.—DR. GIULIO DOZZI (*Gazz. Med. Ital. Prov. Venete*, Sept. 23, 1882) relates the case of an old woman, aged 70, who, after eating a large quantity of watermelon, and swallowing the seeds, suffered from obstruction of the bowels. Purgatives and injections had been tried with no relief. The meteorism was enormous. He determined to try entero-puncture, using trocar No. 2 of Dieulafoy's aspirator. Four punctures were made, two in the right iliac region, the third in the left upper fourth, and the fourth in the left lower fourth. From three punctures issued an immense quantity of gas; from the fourth no gas, the trocar being plugged with fecal matter. A dose of oil given the same evening procured four copious evacuations, and the patient made a good recovery. One of the punctures gave rise to a small abscess. In this case peristaltic action was evidently prevented by the enormous quantity of gas arising from the decomposition of the retained feces.—*London Medical Record*, February 15, 1883.

THE LOCAL TREATMENT OF LUNG CAVITIES.—A. SOKOLOWSKI reports two cases of phthisical lung cavities, into which he made six injections of from six to twenty drops of a ten per cent. tincture of iodine, with a view of obtaining adhesive inflammation of the walls of the cavity. The cough became more violent, but there was no increase in temperature: after two months the destructive process had considerably extended; the result was therefore negative. In the second case, in which severe fever and colliquative sweats were present, five injections of ten drops of a twenty per cent. carbolic acid solution were made. The result was also negative.—*Centralb. f. klin. Med.*, February 3, 1883.

EXCISION OF THE PRIMARY SORE IN SYPHILIS.—PROF. TARNOVSKY (*Monat. f. Prakt. Dermatol.*) comes to the following conclusions:

1. That the primary syphilitic sore is from the moment of its appearance an evidence of constitutional infection.

2. Usually the wound heals easily after excision, and there is no return of the induration in the place; but there is no change in the course of the constitutional state; and

3. That there is no shortening by this means of the time required in treating the primary sore.

On the other hand, under the care of Prof. Grube, five cases were thus treated, and in two no secondary symptoms appeared after a lapse of seventeen and eighteen months respectively.—*Canadian Practitioner*, March, 1883.

THE VALUE OF KOCH'S RESEARCHES.—Koch has met with another opponent, this time in Germany, in the person of DR. SPINA, of Vienna, an assistant of PROF. STRICKER, who claims that many of Koch's experiments are incomplete and erroneous, and his conclusions unwarranted. He shows that the bacilli of Koch possess no characteristics which can separate them from the bacteria of putrefaction; that it is not proved that all of "Koch's bacilli" are of the same character; that they are not constant in tubercular masses, and that their extent does not correspond to the extent of the disease. He further finds fault with the characters of Koch's inoculation experiments, and denies Koch's assertion that the tubercle bacilli only multiply at a temperature corresponding to that of mammals.—*All. Wiener Med. Zeit.*, February 13, 1883.

SURGICAL DILATATION OF THE PYLORUS.—In an individual suffering from pyloric stenosis from a cicatrix, PROF. LORETA, of Bologna, after having made an incision in the epigastrium, and opening the stomach, mechanically dilated the pylorus. The result was most successful, since, on the seventh day, the phenomena caused by the stenosis had disappeared, and the patient was going on well in every way.—*London Medical Record*, February 15, 1883.

TREATMENT OF FURUNCLE.—M. E. LABBÉ thinks that the classical treatment of furuncle by incision and poultices should be abandoned, as an incision never permits all the pus to escape and poulticing simply softens the epidermis and allows of renewed inoculation. His plan is to surround the base of the furuncle with a ring of collodion, and then use the unguentum fuscum (*onguent de la mère*) as a topical application.—*Journ. de Méd. de Paris*, February 17, 1883.

A NEW FUNCTION OF THE RED-BLOOD CORPUSCLE.—From an elaborate experimental study, DR. G. FANO believes that he has succeeded in demonstrating that peptones, whether transfused or absorbed from the digestive tract, are directly transformed into blood by a process of disintegration by which coagulable albuminoids and globulin are produced. The red-blood corpuscle is the active element in producing this change, which results in a direct increase of specific gravity; probably its potassium salts are derived from the peptone.—*Lo Sperimentale*, 1882, pp. 256, 370.

TREATMENT OF OVARIAN CYSTS BY INCISION AND PERMANENT DRAINAGE.—DR. GEO. F. FRENCH believes that the operation of incision and permanent drainage of ovarian cysts should supersede all incomplete operations, and should generally be resorted to in all cases of extensive adhesions to the large intestine, bladder, uterus, liver, stomach, spleen, or brim of the pelvis. The alternative of incision and permanent drainage is either abandonment of the case, an incomplete operation, or enucleation. An operative procedure which provides for any portion of a pyogenic membrane being left in the peritoneal cavity without drainage needs only to be referred to to be condemned. The formidable nature of the operation of enucleation is indicated by the rarity of its performance. He can find no reference to the operation by Spencer Wells in his one thousand ovariotomies, and Schroeder resorted to enucleation but once in two hundred and seventy-six operations. Enucleation in suitable cases is no doubt a feasible operation, but always a very hazardous one.—*American Journal of Obstetrics*, March, 1883.

FOR MASKING THE ODOR OF IODOFORM, DR. C. SCHERK (*Pharm. Zeit.*, 1882, p. 740) recommends carbolic acid. On rubbing together 10 grms. of iodoform with .05 grm. carbolic acid and 2 drops of oil of peppermint, the disagreeable odor of iodoform is completely masked and will not appear again even on heating. The addition is somewhat less effectual if vaseline be used for the ointment; but is still more agreeable than tonka, balsam of Peru, oil of caraway, or oil of peppermint alone.—*Amer. Journ. of Pharm.*, March, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.

SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MARCH 10, 1883.

POISONING BY CHLORATE OF POTASSIUM.

WE have already, in these columns, set forth, with some particularity, the dangers to be apprehended from the free and rather indiscriminate use of chlorate of potassium since its introduction into domestic practice. Further observations on these dangers seem to be demanded in the interests of the public, and fresh warnings may be needed by the medical profession. Indeed, we have reason to believe that many physicians of large experience are sceptical in regard to the supposed toxic activity of this drug. The evidence is, however, conclusive.

In a recent issue of the *Berliner klinische Wochenschrift*, Dr. Riess gives the details of a case of poisoning by chlorate of potassium. About one ounce of the salt, which had been prepared for gargling the throat, was swallowed in the course of two hours. Not to weary our readers with needless details, it will suffice to say that gastro-enteric inflammation was produced, jaundice and suppression of urine followed. A microscopic examination of a drop of blood, obtained from the finger, disclosed important alterations. The red corpuscles were changed in shape, in diameter, and in structure. They were somewhat shrunken, ovoid, and, in part, the coloring matter in granules floated free in the serum. On spectroscopic examination, no deviation from the normal was discovered, because, indeed, none of the constituents were wanting. The autopsy disclosed wide-spread changes. The muscles, including the cardiac, were brownish-red; there were ecchymoses under the endocardium and the mucous membranes at various points; the kidneys were stained with bile pigment, the epithelium fatty and pigmented, and the capillaries choked with broken-down blood corpuscles and pigment cells; the liver relatively small, jaundiced, and the cells, especially about the central vein and along the ramifications of the portal vein, filled with pigment granules.

These observations, thus briefly outlined, confirm the previously made clinical and experimental studies of Marchand, referred to by Riess ("Ueber Intoxication durch Chlorsäure Salze," *Virchow's Archiv*, Band 77, s. 456). The confirmatory evidence is, indeed, much stronger than Riess' references would indicate. He mentions Hofmeister and Friedlander, but besides these, Buccheim, Köhler, and Ludwig, in Germany, Isambert and Richet in France, Dreschfeld, Stock and others, in England, Jacobi in this country, have published cases showing the toxic activity of chlorate of potassium, or have indicated the source and character of the dangers to be feared from its reckless administration. We can readily refer any of our readers, desirous of making further investigation, to the papers above indicated.

All familiar with the history of this agent will recall the sad fate of Dr. Fountain, of Iowa, who, entertaining some extravagant notion of the curative effects of chlorate of potassium in phthisis, and firmly convinced of its innocuousness, swallowed an ounce of the salt to demonstrate its harmlessness. The results observed in all the cases above referred to happened to Dr. Fountain. Gastro-enteric inflammation, disorganization of the blood, jaundice, and suppression of urine followed the ingestion of the fatal dose, and death ensued on the seventh day.

It is not alone the lethal or toxic dose which is capable of doing mischief. Dr. Jacobi, than whom no one is better entitled to speak authoritatively, warns the profession against the indiscriminate employment of chlorate of potash in throat affections. If an attack of tonsillitis, stomatitis, pharyngitis, or what not occurs, chlorate is prescribed. In the form of troches, powders, solutions, etc., almost every household contains it for free use in these affections. It is this indiscriminate employment of the chlorate that Dr. Jacobi condemns, for his abundant experience has furnished him with many cases of renal disease induced by it. That such an opinion is amply justified in the results of the toxic action of the remedy, is only too evident from the facts which we have submitted to our readers.

By way of supplementing these observations, we submit the conclusions of Wegscheider, arrived at after a study of thirty cases of poisoning by chlorate of potassium.

The general phenomena of fever, agitation, dysp-

nœa, etc., present nothing of a characteristic nature, and hence are not dwelt on by the reporter. He presents the symptomatic expression of the cases in an order which we may advantageously follow: On the part of the skin, icterus and ecchymotic patches; on the side of the kidneys, diminished or suppressed urination, the urine containing albumen, Hoppe-Seyler's methæmoglobin, and a brownish pigment deposit. From the point of view of the anatomical changes, he notes, in the kidneys, the blocking of the canaliculi with masses of blood pigment, and parallel changes in the spleen and spinal cord. All the organs present an extremely characteristic chocolate discoloration.

Thus, from a large number of cases, there is a confirmation of the opinions we have expressed. Our readers should not, however, draw the conclusion that chlorate of potassium is too dangerous a substance to be employed in the treatment of disease. Rightly used, in proper doses, there can be no objection to its administration. Its indiscriminate and protracted use; its lavish application, topically and by the stomach; and its reign in the household as a remedy of universal utility, are to be deprecated and opposed by the medical profession, and by the organs of professional opinion. In suitable doses, and in affections to which it is properly applicable, there can be no well-founded objection to its administration.

COLORED HEARING.

A curious, and but little known fact, is that with certain individuals the hearing of sound is always accompanied by sensations of color. The first published observations upon this subject seem to have been made by Nussbaumer (*Wiener med. Wochenschrift*, 1873). Both this writer and his brother habitually experienced such double sensations, and even found that with each note of the musical scale a special color always appeared. Bleuler and Lehman afterward confirmed these observations, and reported that they had examined five hundred and ninety-six individuals who had this peculiarity. These cases all occurred in Germany. An article on "Color Hearing" appeared in the *London Medical Record* in December, 1881. In the November number of the *Annales d' Oculistique*, Pedrono reports in detail a case of this kind. The individual who is the subject of these double sensations discovered quite accidentally that his condition was peculiar. He had always been conscious that sound, especially that of the human voice, invariably awakened a sense of color, and that the same voice always called up the same color. On one occasion, however, a person speaking to him of a friend said, "Have you remarked his voice? It is as pretty as a yellow dog." Pedrono's patient replied very seriously, "Not at all, his voice is red, not yellow." Whereupon the bystanders roared with laughter.

Pedrono found in this case that each note of the musical scale produced a sensation of color; but, although his subject was an excellent musician, he was not able to define a special color for each note. High notes were accompanied by brilliant, low by sombre colors. But if two consecutive notes of the scale were compared, the colors appeared nearly identical. In a perfect chord a single color was produced. For instance, the chord in F major produced yellow, while that in A minor produced violet. But in an imperfect chord some of the notes detached themselves with their proper colors, although very near the general hue.

There was no appreciable difference between the colors corresponding to major and minor tones, between scales in sharps and flats. The same piece of music played upon different instruments produced different colors, showing the effect of timbre. For instance, the Bretonne melody, *Appel des Pâtres*, played on a tenor saxophone was yellow, on a clarionet red, on the piano blue. Intensity of sound produced distinctness of color. With feeble sounds the color seemed to show vibrating movements.

Noises of all sorts provoked chromatic sensations, but the colors were always sombre, generally gray or brown. When the voice was used in a conversational tone the vowel sounds only were colored, *i* and *e* being the most brilliant, *u* the most sombre and *a* and *o* intermediate. The general hue depended upon the timbre of the voice. If the voice was very strongly emitted, the consonants became barely perceptible, the sibilants being brightest. Singing simply intensified these results, each voice retaining its characteristic color. Blue voices were much the most numerous; green the most rare; yellow the most agreeable; red voices were not unfrequent. Of course, different voices represented all shades of these colors.

As to the localization of the colors, all observers seem to agree that they are projected mentally to a point just above the supposed position of the instrument which is sounding or the person who is speaking, and without reference to whether the object is seen or not. A vibrating guitar string appears to be surrounded with color, and a layer of chromatic air rests upon the keys of a sounding piano.

If anything additional to the phenomena of monocular color blindness were needed to demonstrate the existence of cerebral centres for the perception of colors, independently of all other ocular sensations, the facts adduced, in connection with the phenomena of colored hearing, would seem to be sufficient. If this be admitted it would seem unnecessary to imagine an anatomical arrangement of the nervous elements of the retina capable of analyz-

ing luminous rays. Such analysis would be more fittingly performed in the great central cerebral laboratory, and the ingenious, but artificial and gratuitous, theories of Young, Helmholtz, Hering, etc., would be no longer required. The part played by the retina then is possibly merely to furnish the necessary sensory apparatus capable of being excited by light and color in their varying phases. But the resultant molecular vibrations of the optic nerve fibres affect, according to their nature, the appropriate cerebral centres of light, form, or color.

Whether the auditory and color centres are contiguous or are distant and connected by abnormal nerve fibers, in color hearers, it is perhaps useless to discuss here. But as sounds and colors do not correspond in all cases the latter supposition may possibly be correct. With Nussbaumer each musical note produced constantly a special sensation of color, but in Pedrono's case the color was determined by the timbre of the voice or instrument.

It seems to us that the appellation "Colored Hearing" is more applicable to this class of cases than the title "Color Hearing" which has heretofore been used. As the color perceived is manifestly a subjective excitation of the cerebral color centre, and only accompanies the sound, it is evident that the person cannot be said to hear colors which do not exist, but only that the sensation of hearing is attended by color.

SIR JAMES PAGET'S BRADSHAWE LECTURE.

THE Bradshawe Lecture is a new foundation established under the auspices of the Royal College of Surgeons of England, by the widow of Mr. William Wood Bradshawe, as a memorial of her husband.

The initial lecture on the foundation was delivered last year by Sir James Paget, and has been republished in pamphlet form. It deals with "some rare and new diseases," *i. e.*, diseases which probably are new within the present century, and while at first rare are now more common: and with the reason for this fact, due, as Paget believes, mainly to morbid conditions changing and continuing in transmission from parents to offspring. Three very excellent, chief illustrations are chosen, the arthritis of ataxics, first described by Charcot; osteitis deformans, first described by Paget himself; and phlegmasia dolens in males. All of these diseases involve such gross, macroscopic changes that the shrewd early observers who depended upon their unassisted eyes alone, and, therefore, it may be were even more on the alert to observe such changes, than we in these days of microscopic research, must have seen and described them had they met with such cases. Moreover, if only as curiosities, they would have certainly preserved bones with such changes as Charcot and Paget have described. But, in fact, no early specimens of such bones exist in our museums, and hence we must believe the diseases to be new. Brodie and Stanley, with their wide experience, never saw any case of osteitis deformans save the one Paget showed them twenty-five years ago, yet of the thirteen cases, the latter has seen in this period, seven have been noted in the last six years.

The study of "sports," or variations in botany, of hybrids and mongrels in vegetables and animals, has given Darwin many strong points in his investigations on the origin of species. Similarly, Sir James Paget advises the study of such variations of types of disease in pathology, and their relation to the standard as affected by the ever-increasing and variously combined factors in hereditary descent. Their existence may be attributed to several causes. Thus the exact counterpart of the parent is never produced. The offspring always varies this way or that, towards more perfect health or towards more marked disease; and this tendency to variation is increased by the commingling and modifying influences of the double parentage. Reversion to the types of earlier generations plays a not unimportant *rôle* in some cases; while benevolence towards the weak, a constant element in educated humanity, tends to preserve these variations from the standard of health, and to allow them to propagate, it may be, still more divergent forms.

Much of our imperfect and faulty therapeutics lies embedded in our ignorance of such types of disease. Cases deemed alike, and therefore treated alike, are often really different. Not only the good seed is needed for the abundant crop, suitable soil is also quite as necessary. Every one has peculiarities of blood, plasma, bone, muscle, nerve, which we as yet fail to recognize save by ultimate knowledge of the "constitution," *i. e.*, all the factors of health and disease of the patient and his progenitors.

Perhaps no one of our profession now living so well illustrates the aphorism *nihil tetigit quod non ornavit*, as does Sir James Paget. Eminent both as a surgeon and a pathologist, as an orator and a medical essayist, a master of flowing English, and a painstaking and shrewd observer of facts and their correlations, he writes nothing which is not worth reading, he says nothing which is not worth remembering.

To all this he adds a kindness of heart and of manner that win our affection as his learning claims our respect. No one who heard his excellent addresses at the London Congress of 1881, could fail to long for equally happy resources as a public

speaker, and every one who reads the Bradshawe lecture, will alike envy him his wide reading, his accurate observation of disease, his powers of illustration, and his charming style. The inauguration of such a course of lectures by such a man, is a happy coincidence not often seen.

WAS THERE EVER SUCH A SPECTACLE!

IN the discussion of an appropriation for the National Board of Health, in the House of Representatives, Mr. Ellis, of Louisiana, held up to ridicule the investigation of Prof. Mallet into the pollution of water, a work, undertaken by direction of the Board, which has yielded most important results. Prof. Frankland, of the National School of Science, South Kensington Museum, London, says of this investigation of Prof. Mallet: "I consider it to be one of the most important contributions ever made to our knowledge of the propagation of epidemic diseases." In order to fully appreciate the wit of the honorable member from Louisana, which convulsed his learned fellow-members, it is necessary to say that the biological investigations were conducted in the laboratory of Prof. Martin, of Johns Hopkins University, and consisted in testing the effects of the water pollution upon rabbits by subcutaneous injections. In the following language, redolent with Congressional eloquence, the member from Louisiana paints an imaginary scene:

"'Now listen, all ye gods!' What a spectacle! In the heavy slumbrous air of the tropics the Angel of Pestilence is hovering with lungs breathing poison and outstretched wings from which death drops, preparing to swoop with the death instinct of the vulture and the fierceness of the condor upon the Southern coast. Cities grow pale and the land cowers with dread and men cry for help from the threatened death. Where, then, is the National Board of Health! Gathered about a table, that distinguished body is engaged in injecting a certain kind of water under the skin of a rabbit, just to see how the rabbit would like it, and how the health of the rabbit will be affected by it. [Great laughter and applause.] Was there ever such a spectacle!"

We answer, truly, there never was such a spectacle as this Congressional scene presented! There is probably not a deliberative body in Europe which would not have hissed with scorn at such allusions to a scientific investigation by a department of government. When we contrast such puerilities of our statesmen with the action of the British Parliament, which not only listened with profound respect to the long series of observations and experiments by which Jenner established the value of cowpox as the great and unerring preventive measure against smallpox, but voted him a half million of dollars as a reward for his services, we can appreciate the immense superiority as regards intelligence of foreign as compared with American statesmanship.

If by such stuff Congress can be led to destroy a branch of the public service of its own creation, which has won the gratitude of half the people of the United States, and the respect of the scientific world, there is little hope of soon having a permanent and useful health organization connected with the general government. That the public money will hereafter be freely expended in case of epidemic outbreaks there is no doubt. Nor is it less doubtful that it will ultimately be demanded that the medium selected for that purpose shall be some compliant political agency.

M. ONIMUS, who is known to be one of the highest authorities on the physiological effects of electricity, has lately been studying the effects of different electrical currents on uterine action. He maintains that the unimpregnated uterus contracts but feebly under the stimulation of electrical currents, as, indeed, of other agents. In the gravid state, on the other hand, its excitability is far greater. He finds that galvanism has more effect than faradism, and that both currents act more vigorously when the uterus is spontaneously in action, a fact in entire accordance with professional opinion.

MASSINI has lately compared the effects of bromhydric acid with bromide of potassium, and with monobromated camphor. He finds that its taste is not disagreeable, and that it is better borne by the stomach than are the other agents. He administered it in the various maladies for which the bromides are prescribed, and finds it to be an excellent substitute. He advises that it be given fifteen minutes after meals, and in doses of twenty drops of the ten per cent. solution, which corresponds in strength with the formula of the Pharmacopœia of 1880. He has not observed any ulterior bad effects from its persistent use.

THE oldest two training schools for nurses, in this country, are that of the Philadelphia Lying-in Charity, organized in 1836, and that of the Woman's Hospital, in 1861. The latter has heretofore graduated nurses as they terminated their courses of study at various periods in the year. They have decided, however, hereafter to hold annual public commencements. The first one will be held in the new Clinic Hall of the Woman's Hospital, on Wednesday, March 14th, at 4 P.M., when several addresses will be delivered by friends of the school.

Members of the medical profession are especially invited to attend.

On page 287 our readers will find the record of the yea and nay vote at Albany, on the motion to repeal the new Code. For this interesting reading we are indebted to advance sheets of the *Ephemeris*, which have been kindly forwarded to us by Dr. E. R. Squibb, of Brooklyn.

REVIEWS.

Nervous Diseases: Their Description and Treatment. A Manual for Students and Practitioners of Medicine. By Allan McLane Hamilton, M.D., Fellow of the New York Academy of Medicine, one of the Attending Physicians at the Hospital for Epileptics and Paralytics, Blackwell's Island, New York City, etc. etc. Second Edition, revised and enlarged. With seventy-two illustrations. Philadelphia: Henry C. Lea's Son & Co., 1881.

On the first appearance of Dr. Hamilton's book, it met with harsh criticism and high commendation. Surviving both, it has come in a reasonable time to a second edition. The charges of plagiarism so freely brought against it by certain reviewers cannot be fairly sustained. Most text-books are largely compilations; and Dr. Hamilton's work has much less of technical plagiarism in it than some other recent volumes on diseases of the nervous system. The treatise of Ross, for example, might be cited in this connection. Many of the errors of the first edition have been corrected, and nearly one hundred pages and many new illustrations have been added.

Occasional evidences of carelessness are to be found scattered throughout the book, as where Greisinger is spoken of, instead of Griesinger, or Leibreich for Liebreich; or where, on page 497, he speaks of one physician as having had very successful results with the bromide of iron in chorea; and in the next sentence says that, in twelve patients to whom he administered the drug, there was no improvement after its use.

Some new matter with reference to localization has been introduced into the present edition. We note with pleasure the reproduction, on page 273, of Dr. Gowers' diagram and table showing the approximate relation to the spinal nerves of the various motor, sensory, and reflex functions of the spinal cord; but in naming the illustration the expression "spinal cords" is used instead of "spinal nerves."

We can heartily commend the book to students and practitioners as a convenient manual upon nervous diseases.

The Art of Voice-production, with Special Reference to the Methods of Correct Breathing. By A. A. Pattou. 12mo. pp. 106. New York: G. P. Putnam's Sons, 1882.

Simply a little manual for teachers of singing, and for amateurs, indicating the proper and improper methods of respiration and vocalization; reinforced, here and there, by extracts from physicians and vocalists who have written more or less fully on the subject. It is not intended as a medical manual in any way. We have no doubt that its circulation among vocalists will be productive of much benefit.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting February 13, 1883.

The President, T. M. Markoe, M.D., in the Chair.

Dr. George A. Peters reported:

TWO CASES OF SARCOMA—AMPUTATION—POST-MORTEM AND MICROSCOPICAL APPEARANCES; REMARKS.

Case I. Sarcoma of Forearm; Amputation of Arm.—Julia G., born in U. S., aged 21, single, was admitted into New York Hospital, August, 1882. Fine, healthy-looking woman; no hereditary history of cancer; family history negative; no specific history. Nine months before admission, a small lump appeared on the under surface of the right forearm, quite painful at night, at times throbbing and beating. It increased in size but little until four weeks ago, when local symptoms of phlegmonous inflammation came on, and the swelling increased rapidly in size; it opened, and considerable pus was discharged. Since that time the tissues have broken down, forming a large ulcer, which has continued to increase in depth and circumference; is very painful, and from the surface there is a slight grumous and foul discharge. General health seems to be but little affected.

Examination shows on the ulnar side of the right forearm, at its middle third, an irregular, circular ulcer, with a diameter of two inches; edges elevated and everted; undermined, and surrounded by a dusky-red areola; surface irregularly excavated and deep, presenting a sloughy, fungous appearance. The surrounding tissues are indurated and thickened; the induration and œdema extending on posterior aspect of the limb up to elbow-joint. Axillary glands not enlarged. Ordered the parts poulticed.

August 27.—Poultice was stopped, and powdered naphthalin was dusted over the ulcer. *28th.*—The ulcer was found to have increased in size, the longest diameter two and a half inches; the widest one and seven-eighths inch. The cavity was filled with naphthalin, with light dressing of borated cotton. *Sept. 3.*—Patient complains of numbness in those parts of the hand which are supplied by the ulnar nerve; also pain in the arm along the course of same nerve, and strong flexion of the forearm. *14th.*—Pain in the forearm and hand continues, requiring at times the administration of anodynes; the diameter is about the same as at time of last note, but the cavity is somewhat deeper and more excavated. Induration about the ulcer increased in extent; local tenderness not great; skin in neighborhood red and angry looking. Motion of forearm and hand quite free, except that complete supination is impossible.

15th.—Amputated the arm by the modified circular method. Ether was given, and Esmarch's bandage was applied to control hemorrhage. Anterior flap formed first; incision commenced externally at junction of middle and lower third of the arm; carried in convex direction to corresponding point on opposite side; flap about two and one-half inches long. The posterior flap was then marked out in the same way, being about twice the length of the anterior one. Flaps, composed of skin and connective tissue only, were then dissected back to their base, retracted strongly, and the muscles were divided by a circular sweep with the catlin; bone sawed through; Esmarch's bandage removed, and all bleeding arteries secured with carbolized catgut ligatures. Parts were then thoroughly washed with carbolic acid solution, one part to forty; India-rubber drainage-tube placed across the face of

the stump, deep down; edges of the flaps were then closely sutured with carbolized catgut, the drainage-tube left long at each angle, and the stump was wrapped in a complete Lister dressing, through which the drainage-tube projected.

16th.—Patient slept well during the night; tube was syringed out with weak carbolic solution every three hours. Slight sero-bloody discharge through tube. No discharge through the dressing. Temperature 100.2° F.; pulse 122; respiration 24. P. M., temperature 101.4° F.; pulse 140. Some small blood clots were washed out of the tube. Pain, probably due to tight bandaging. *17th.*—Temperature 99.2°; no pain; patient comfortable; but has no appetite. In the afternoon the dressing was removed, and the temperature ran up to 100.6°. Red blush for two inches about the wound. Superficial sloughing and suppuration. All the sutures except one at each angle of the wound removed. No union has resulted. *18th.*—Temperature 99.2°; pulse 126. *19th.*—Yesterday dressings removed, and remaining sutures taken out. Redness has disappeared, wound drains well, no accumulation; superficial union only at outer angle of wound, the rest has entirely broken down. Flaps brought together with adhesive strap, tube removed, and peat dressing applied. *21st.*—Dressing removed; free suppuration; no pocketing; union of subcutaneous tissue in outer half of wound, but a sinus runs beneath this bridge from outer angle to near the inner third of wound. On inner third the granulations are springing up from the bottom, large, florid, and healthy. Peat dressings reapplied; temperature normal. *24th.*—The cavity is rapidly filling up; deep union throughout the wound. Dressed as before. *October 5.*—Dressings removed; granulations have come up to level of the skin, a figure-of-eight ulcer remains, skin having closed in centre of stump, width of granulating surface at either extremity two inches. Slight discharge of pus. Dressed as before. *14th.*—Dressing removed; ulcer reduced to about one inch in width. Dressing changed to adhesive plaster straps, and small peat-bag compress. *24th.*—Only a small ulcer left at inner side of stump. Patient discharged cured.

Case II. Sarcoma of Arm.—Augustus B., age 35, single, cook, was admitted September 20, 1882, into St. Luke's Hospital. Four months ago the patient first noticed a tumor on the back part of right arm at lower third. He had never met with any injury in this situation, and does not think he had ever strained the muscle. The mass was the size of a walnut, and grew slowly without any pain. It was poulticed and became softer. Three weeks ago it became painful, swelled a good deal upon the outer side, and was opened, a large amount of thin bloody fluid escaping. Immediately after admission into the hospital, the incision was slightly enlarged, probe introduced, but failed to touch bone; the finger was entered, and the cavity explored. Considerable clotted and fluid blood was pressed out. Among the clots were some fleshy masses, which on section were greenish in color with yellow spots. No specific history, no family history of tumor. On admission his general nutrition was fair.

Examination shows a large tumor on outer and posterior surface of right arm. Circumference, twice that of left arm; tumor measures from above downward seven inches; from side to side nine and one-half inches; mass reaches up as high as the insertion of the deltoid muscle; downward to three and one-half inches above the lower end of the humerus. It is soft and fluctuating; not connected with bone; not movable; not tender to touch; seems to be contained entirely within the limits of the triceps muscle, and to be to a large extent embedded in it. Posteriorly and below there seems to be a distinct capsule. Tumor not lobulated. At a point near the insertion of the deltoid, there is a distinctly indurated spot. The skin over the tumor is reddened and adherent. On the outer side at middle third is an incision, from which issues a watery discharge, mixed with blood. Sections of the fleshy masses under the microscope showed them to be made up of cells of mixed character. Chiefly round, some spindled, and varying in size; many with a homogeneous, and in parts fibrous intercellular substance. There are many blood extravasations in and around which are groups of small round, non-nucleated cells. There are some bloodvessels filled with organizing clots, the walls of which show a cellular infiltration, gradually assuming the same character as above mentioned. Diagnosis: mixed celled sarcoma. Ordered carbolic dressing.

Sept. 23.—Since admission has had several hemorrhages of dark venous blood. This morning a considerable amount of clotted and fluid blood escaped. *25th.*—Last night, lost several ounces of blood. *Oct. 4.*—Patient has not pain; considerable discharge; carbolic dressings continued; temperature went up to 103° F.; says he feels well. *5th.*—The integument over the upper part of tumor has a suspicious redness; patient says that he had a slight chill in the night; temperature, 101°. *6th.*—Temperature 100°; feels in good condition; has no pain; redness disappearing; œdema very slight. *11th.*—Discharge slight; no pain; œdema and redness entirely gone from shoulder; on consultation, it was determined to amputate the limb at the shoulder-joint; this I did on the 12th, Drs. McBurney and Bull assisting; the method of Baron Larrey was adopted, viz.: A longitudinal incision involving the tissues down to the bone on the external surface, and extending from the acromion to a little below the neck of the humerus. This incision is continued on each side through the skin only, circumscribing the arm about two inches from the axilla. All the tissues about the head of the bone were now cut through, keeping the edge of the knife close to the bone, adduction and rotation being made as required. The head of the humerus was forced out, a long amputating knife was now passed down behind the bone, and the undivided muscles and the skin were cut through, the main arteries being secured between the thumb and fingers of an assistant, who followed the catling and grasped the flap. The bleeding vessels were immediately secured with carbolized catgut, the wound thoroughly washed out with carbolic acid solution, one to twenty; edges of the flap were brought together with interrupted carbolized catgut sutures; free drainage was secured by a rubber tube along the bottom of the wound emerging through an opening in the skin made for the purpose, about an inch below the lower angle of the wound; the stump was then covered with a layer of iodoform gauze, and a Lister dressing over all. In this case the drainage-tube was cut short. What is called through drainage was not used. The patient was so much exhausted by the operation as to require three or four hypodermic injections of brandy before he was removed from the operating table to the ward. *13th.*—The patient made good recovery from the ether. Pulse was good; temperature 101°. During the first twenty-four hours, the discharge appeared through the dressings, and they were removed and reapplied. The wound is looking well; no pain. *14th.*—Temperature, 102°; discharge came through; no odor; dressings reapplied. *18th.*—The tube was shortened; all sutures removed; a slight gaping at the middle of wound; temperature 100°; dressings reapplied. *20th.*—Temperature normal; tube removed; dressed with balsam of Peru and straps. The patient soon got out of bed and moved about the ward; eating and sleeping well. Two of the sinuses which existed refused

to heal, notwithstanding the variety of dressings used. At intervals of a few days there would be a rise of temperature and a temporary set-back. *Dec. 15.*—I etherized the patient and laid the sinus freely open for a distance of three inches or more down to the glenoid cavity, packed with Lister gauze, wet with one to forty of carbolic solution. The patient kept about the ward, complaining but little, but the last wound seemed to make but little progress in healing. What he did complain of was a slight cough at night, which was temporarily relieved by drugs. No râles were heard. Physical examination revealed nothing. This condition continued until January 29, 1883, when he complained of more pain in the left side only and more cough. A careful examination gave indistinct physical signs of a small quantity of fluid in the right chest cavity; some pleuritic râles on both sides; bronchial breathing and diminished respiration. *Jan. 30.*—Pysical signs indistinct. On the posterior part of the right lung, at the lower angle of scapula, a small area of cavernous breathing was made out. A hypodermic needle was introduced into the left pleural cavity, and bloody serum, containing a few pus cells, was withdrawn. The patient was transferred to medical service. Soon after this tranfer paracentesis was performed, and sixteen ounces of bloody serum were removed from the left chest. This gave marked relief, and the cyanosis disappeared. His dyspnœa, however, soon returned, and he gave evidence of rapidly increasing chest trouble. The hypodermic needle introduced into the right chest gave no fluid. Supposed sarcomatous infiltration of right lung. He gradually sank into a stupor, and at 11.30 o'clock P. M. he died.

Autopsy.—Body well nourished, rigor mortis well marked; there is no œdema; right arm amputated at shoulder-joint. There is union of the flap, except at one point where there is an opening large enough to admit a probe one-fourth of an inch in diameter. Peritoneum is normal; diaphragm is at level of sixth rib on either side of the thorax. There are old adhesions at apex of the left lung, and over upper lobe in axillary line. Also old loose adhesions over the lower lobe posteriorly, there are old loose adhesions at apex of right lung, and also over the middle lobe anteriorly. There is about a pint of bloody serum in each pleural cavity. Heart is rather small, valves competent; endocardium of left vertricle is thickened; muscular tissue brownish. Lungs: Through both lungs, except upper portion of upper lobe of each, there are soft tumors, grayish in color, with hemorrhage into their substance in places; these are spheroidal in shape, varying in size from that of a pin-head to that of a hen's egg. Some of these tumors contain a number of cysts, which vary in size from one-eighth to an inch in diameter. The lung tissue free from these tissues, is intensely œdematous and congested. Bronchial tubes contain muco-pus. Spleen is seven by three, by one and one-half inches; is normal in appearance. Kidneys normal in size; capsules adherent; surface smooth; the cortex seems normal; there is fat in the straight tubules near the apex of pyramids. Stomach: Mucous membrane normal; intestines normal; pancreas normal; bladder normal. Right shoulder in seat of amputation had a fleshy mass, spherical in shape, about two and one-half inches in diameter, similar in consistency and appearance to secondary tumors already described in the lungs.

DR. G. L. PEABODY, pathologist to the hospital, reports as follows:

Case I.—The tumor is diffused through a muscular mass on the ulna, but does not invade the bone. Beneath the surface of the ulceration, which is covered by fibrine and granulation tissue, are large masses of small spindle and round cells with very little fibrous stroma. Under these is a dense layer of connective tissue, which contains smaller masses of cells of the above description. In this layer are numerous blood-vessels with areas of dense cellular infiltration surrounding them. In the muscular tissue are many dense isolated collections of small round cells, usually in close relation to the bloodvessels. These latter collections have separated muscular fibres from their neighboring fibres in many instances, and in other localities have apparently destroyed muscular fibres by pressure, a granular structureless mass being substituted for them. Elsewhere the perimysium is increased in amount in the neighborhood of these collections of cells, the muscular fibre being proportionately destroyed. Diagnosis: Sarcoma.

Case II.—On dissection the tumor is found to occupy the middle third and part of the lower third of the triceps muscles, leaving only a thin layer of muscular tissue betwen it and the bone. It involves the subcutaneous tissue over part of its surface; the skin only where the opening exists. The tumor is five and one-half inches long by three inches wide; the cavity contains blood-clots. The tumor, on section, is of the consistency of jelly, of a dirty gray color, and shows numerous ecchymotic spots. Examination of threads of tissue from cavity before operation showed round and spindle cells with many bloodvessels, whose walls were infiltrated by these cells. Microscopic examination of the tumor shows it to consist chiefly of medium-sized spindle cells, and some round cells, with a very small amount of fibrous stroma. There are a few giant cells and numerous bloodvessels. In the section many areas of spindle cells have been cut transversely, making them appear round. Diagnosis, sarcoma. The extremity, including the tumor, was injected on its reception. The blue areas in the section show many bloodvessels; the injection was only partially successful, the limb having become too cold during the transportation from St. Luke's Hospital to allow the injected mass to flow freely. On microscopic examination, the tumor in the seat of the operation and the secondary deposits in the lung are anatomically the same. They are chiefly made up of large and small spindle cells, a small amount of stroma, and bloodvessels. There are also throughout the entire tumor and secondary deposits small round cells, and a few large multinuclear cells. The spindle cells are furnished with large oval nuclei, and separated by a small amount of intercellular substance. The blood supply is abundant, the walls of the vessels being made up of sarcomatous tissue. The cysts associated with the secondary deposits in the lung contain a brownish fluid, which is composed of blood, fibrine, and cells, similar to those described above. The walls of the cyst are made up of different layers of large spindle cells and fibrin. Sections through the bronchial glands show similar structure to the tumors and secondary deposits.

We have here two well-marked cases of sarcoma, commencing evidently in the connective tissue, between the muscular fibres, and rapidly spreading through the muscle. In neither case was the periosteum invaded. We know very well that the common seat, perhaps the most common seat of sarcoma in the limbs is in the connective tissue beneath the peritoneum, or in the medullary cavity itself; the bone finally becoming involved. The sarcomatous tumor situated in the muscular substance has, as a rule, no capsule, but dips down between the fibres, blending almost imperceptibly with healthy tissue surrounding it. Consequently, the golden rule which is to be observed in the removal of tumors, namely, to get well down upon the capsule, and thus ensure easy enucleation, cannot in these cases be followed. There is no investing capsule. The rule in such tumors is to go wide of the apparent boundary

so as to remove all the disease. This entire removal is so difficult and uncertain that where the tumor is situated upon the arm or legs, and has reached any considerable size, amputation of the limb is considered the wiser and safer procedure, and the amputation should be done at a distance from the disease, at or above the next proximal articulation. Unfortunately, however, even this precaution will not secure immunity. These mixed-cell sarcomas are so prone to recur that we are not able to give a patient much hope that even removal will cure. In the large majority of cases the poison works rapidly, and often before the wound made by the knife heals the tumor recurs, either in the neighborhood of its first habitation, in the cicatrix, or in some of the internal organs, notably the lungs. In Case II. the arm was removed at the shoulder-joint, at a distance above any apparent infiltration of tissue. There was no enlargement of axillary glands, and in so far as could be learned by careful physical exploration, there was no contamination within the trunk. He recovered from the operation so as to be about; was well nourished, and had good courage and an abiding faith that he would recover; yet within a period of less than four months the disease had recurred in the cicatrix, and both lungs were thickly studded with kindred tumors. A remarkable feature of this case was, that with all this appropriation of lung tissue by this diseased growth, he had no suffering until within a few hours of his death; when dyspnœa became distressing.

Case I. has progressed more favorably. After her discharge from the hospital, October 24, 1882, with only a slight ulceration at angle of the stump, she returned in the course of a fortnight or so with a condition of the limb which we feared might be a recurrence, but which proved to be only an acute phlegmon, which, under treatment, rapidly subsided, and she was finally discharged cured. She reported herself a few days ago, at which time there were no symptoms pointing to a return, either outside or in. By the kindness of Dr. Peabody, I am enabled to present to you this evening the forearm removed from Case I., and the arm from Case II. The tumor, with all its relations to the surrounding tissue, is best seen in the first specimen. The one from Case II. is more blended and less distinctly marked in its outline, for the reason given in the report the attempt to inject the veins with a colored solution was only partially successful. Consequently their course is not so well shown as I had hoped they might be. Dr. Peabody has also mounted on slides sections of the two tumors, and these specimens show very satisfactorily the internal structure of sarcoma, the various cell growths, the bloodvessels, muscular tissue, and fibrous stroma. The lungs taken from Case II. show abundant deposit of secondary sarcomata, many of which have undergone degeneration.

For notes in these cases I am indebted to Dr. Bartlett, House Surgeon to New York Hospital, and to Dr. Hunter, occupying the same position at St. Luke's Hospital.

Dr. Peters further remarked that he had been unable to find any reference to the relative proportion existing between sarcoma originating in the connective tissue, beneath the periosteum, or in the interior of bones and that originating in the muscles. He thought it probable that the variety originating beneath the periosteum occurred most frequently.

DR. WEIR recalled a case in which he removed a sarcomatous tumor from the lower end of the radius, six years ago, the patient having declined to submit to amputation, which was recommended. Recurrence of the disease took place within a year to a slight extent in one of the upper row of the carpal bones. This bone was removed, and the patient had remained well since the operation. The tumor was a round-cell sarcoma, as was also the tumor for which he had amputated at the hip-joint.

DR. F. LANGE presented the patient from whom he removed a large

TUMOR OF THE UTERUS

three months ago. A short time ago she complained of something like the molimen menstrualis, but this passed away. The stumps of the adhesions with the abdominal walls, which were of considerabls size, and had been secured between the edges of the abdominal cut (treated extra-peritoneally), had entirely disappeared, and Dr. Lange presumed that the ligated tissues had been either absorbed or softening had taken place, and they had become incorporated entirely with the surrounding parts; at all events, nothing could be found of the stumps, of which one, at the time of the operation, was about the size of a walnut.

COLOTOMY FOR ULCERATION OF THE RECTUM.

DR. LANGE also presented a patient upon whom he had performed colotomy for ulceration of the rectum, very obstinate in character, and believed to be of specific origin. The patient had been under his care for three years; had been treated both constitutionally and locally; rectotomy had also been performed, and, so far as the local disease was concerned, with only partial relief. Finally he resorted to colotomy. He first tried lumbo-colotomy, but found that the kidney was somewhat dislocated, and apprehending some interference with the function of the anus præternaturalis, he did not complete the operation, but performed colotomy in front. He showed the patient for one reason in particular. In a paper which he read before the Society some time ago, he mentioned that respiration had some effect upon the kidney, and recited some experiments made upon the cadaver which seemed to make it probable that the kidney might be moved up and down during respiration. The case presented might not prove everything in this respect, but the kidney could be felt near the spinal column, and when the patient was in a horizontal position it could be felt distinctly moving up and down, for a distance of perhaps half an inch or more with each respiratory movement. This movement of the kidney could not be observed while the patient was standing.

DR. WEIR remarked with reference to the influence of colotomy upon ulceration of the rectum, that some time ago he had under observation a patient at the Roosevelt Hospital, who had extensive syphilitic ulceration of the bowel, and on whom he performed linear rectotomy, but no relief followed. Subsequently he performed lumbo-colotomy at the New York Hospital, with the happiest results, so far as the stricture of the rectum was concerned, The patient went out of the hospital with the ulcers healed, and was gaining flesh, but other troubles developed a long time afterward, and she found her way into Bellevue Hospital, where she died; and Dr. L. A. Stimson, who had an opportunity to make an autopsy, found that cicatrization of the ulcers in the rectum was complete and satisfactory.

DR. STIMSON said that there was no marked stricture of the rectum at the time of the autopsy, and that the cicatrization was complete, as just stated by Dr. Weir. The anus in the loin was still open. A notable point was the extensive prolapsus at the lumbar orifice, the intestine hanging out of the opening six or eight inches in length while the body was lying upon the autopsy-table.

DR. WEIR said that a certain amount of prolapsus was liable to take place in every case: but he felt that a step in advance had been made by making the opening in the gut exceedingly small, only sufficient to

admit the tip of the little finger. In the last case, in which he performed the operation for cancer of the rectum, the woman lived a year and a half, and was in every way comfortable, not being troubled with either incontinence of feces or prolapsus of the bowel. The artificial anus was simply supported by a small plug and an ordinary bandage.

DR. A. C. POST operated four years ago for an ulcerated stricture of the rectum, following protracted dysentery, the patient having been treated for a long time in the hospital without progress toward a cure. Within a few months, the patient having evacuations through the loin, the irritation of the rectum so far subsided that the ulcerated portion of the mucous membrane healed, and the rectum was subsequently dilated by the introduction of bougies, so that the patient now has nearly all of his evacuations through the natural passage, an instrument, fifty-eight millimetres in circumference, passing without much difficulty. He saw the patient last week, and at that time there had been an interval of three months since an instrument had been introduced. He found that only slight contraction had taken place, and that the bougie could be introduced with a little more difficulty than when he used it once in two weeks. The result had been very satisfactory in restoring the passages from the bowels through the rectum. There had not been any prolapsus of the colon.

DR. JAMES L. LITTLE had had one case in which there was great difficulty in keeping the opening in the loin patent. After his operation, the case remained under the care of Dr. Porter, a surgeon residing in Middlebury, Vermont, who found that the opening in the integument had a tendency to close. Tents of various kinds were used with but little effect. The wound finally closed, and the patient went six weeks without a movement from the bowels. The doctor made an incision through the cicatrix, dilated the opening with sponge-tents, after which the patient had a thorough evacuation from the bowels. The opening again closed, and it was again necessary to make an incision and dilate it, in order that evacuations from the bowels might occur. This was done three times, the opening remaining closed for about six weeks at each time; it afterwards remained open. The patient lived four years after the operation, which was performed for a growth in the abdomen pressing upon the sigmoid flexure.

The PRESIDENT asked how often a tendency to contract in the opening manifested itself in lumbo-colotomy.

DR. WEIR said that he had not found any tendency in his nine cases to contraction.

DR. SANDS said that he had not observed any tendency to contraction when the operation was performed in that locality. In one case in which he had performed inguinal colotomy, the contraction was very marked, so that it became necessary to dilate the artificial anus with sponge tents and bougies. But in that case the opening into the intestine was very small, not more than one-third of an inch in diameter.

DR. BRIDDON thought that contraction of the opening occurred only in those cases where union had failed to occur between the integument and the mucous membrane, and a fistulous tract remained.

DR. SANDS thought that Dr. Briddon's statement could hardly be accepted as a rule. In the case first referred to, he took particular pains to secure primary union of the intestinal with the parietal peritoneum, by stitching the cut edges of the latter to the skin before fastening the intestine to the abdominal wall, and by then waiting forty-eight hours before opening the intestine. When the opening was made, adhesion was complete between the peritoneal surface of the intestine and the margin of the wound in the abdominal wall. These adhesions did not break down, and he was certain that no fistulous tract remained. The contraction which took place was doubtless due to the fact that the opening in the intestine was a very small one.

DR. POST suggested that the contraction might be more likely to take place if the opening was made into the peritoneal cavity than when made into the retro-peritoneal cellular tissue, as in the loins. He remembered one case, that of a new-born child, in which he performed an operation for absence of the rectum, and was obliged to go very high up and bring down the upper part of the rectum and join it with the integument about the anus. The patient was not under observation for some time afterward, and there was considerable contraction, but he was able to dilate it by the daily introduction of a tent, and ultimately there was full size of the canal.

DR. WEIR remarked concerning non-union of the mucous membrane and the skin, that as it occurred in nearly every instance in his observation, it could hardly be considered as productive of much contraction. The mucous membrane holds only temporarily, as a rule, to the skin, and a few lines of granulation tissue finally glue the parts together.

LARGE VESICAL CALCULUS REMOVED BY LITHOTOMY.

DR. WEIR presented a vesical calculus which he had removed from a man sixty-two years of age, of spare habit; who five years ago began to suffer from symptoms of stone, and was then relieved of a small calculus by the median incision, so far as he could judge from the appearance of the cicatrix in the perineum. A very short time, however, after this operation the symptoms of stone reappeared, and increased in severity, especially during the past year. The urine was continuously bloody and voided every ten minutes in great agony. After putting the patient in bed, elevating the hips, and administering alkalies for a few days, he was sounded. The instrument entered the bladder, which was much contracted, without difficulty, but no rapping sound against the stone could be obtained; only a rubbing could be felt. It could be appreciated, however, by this exploration that the calculus was a large one. There was much tenderness in the hypogastrium, and examination by the rectum showed plainly the encroachment of the stone backwards, and gave great pain. After having examined the urine several times, and not obtaining any special evidence of kidney trouble, the patient was etherized, and a bimanual exploration was resorted to, when a stone about the size of a duck's egg was recognized. In view of the great irritability and contraction of the bladder, and the size of the stone, he determined to resort to lithotomy rather than attempt to remove so large a calculus by rapid lithotrity. The lateral incision was made and a calculus weighing 2070 grains, or four ounces and two and a half drachms, was removed. When he first introduced his finger into the bladder, he thought that there were two stones. The two stones were placed face to face so completely as to convey the impression that he had to do with a spontaneous fracture of the calculus, it was so cleanly divided. A subsequent examination of the fragments revealed that there were three calculi.

With reference to the operation, Dr. Weir remarked that the sound which he employed was the modified rectangular instrument used by Dr. Willard Parker, having a central groove with a decided stop at the end, and Dr. Weir regarded this staff as one affording considerable assistance, especially in operating through a deep perineum, as it afforded a very distinct guide for reaching the neck of the bladder, and also enabled the operator to carry the knife well in without risk of

doing damage, because of the deep groove in the staff. He also used a very broad knife, probe-pointed, half an inch in diameter. He also determined not to attempt to extract so large a stone entire, but to crush it by means of Beketow's or Dolbeau's forceps. Also bearing in mind Crichton's method of operating, whereby so many large stones were extracted, he resorted to the comparatively free incisions, first on one side of the prostate and then to a less degree on the other, in the following way: After seizing the stone and crushing it once or twice, he seized quite a large fragment, the grasp being probably one inch, and was unable to draw it through the prostate. Accordingly, he nicked the prostate slightly upon the other side, and thus gave ready exit to the largest fragment seen in the collection. After the operation had been performed he felt that he had done a minimum amount of damage to the bladder, the prostate, and the perineum, and that he had carried out satisfactorily the technique of the operation. The patient did not present any unpleasant symptoms on the evening of the day of the operation, which was performed on Thursday, February 8th, beyond continued vomiting, which was ascribed to the influence of the ether. The vomiting, however, became persistent, and from the character of the material ejected he began to suspect that either peritonitis was supervening, or that it was due to inflammatory action in the kidney. The condition of the patient, however, steadily grew worse, and he died on Sunday night following. After the operation, and up to the time of his death, the patient said that he had similar vomiting after the first operation, and believed that he would pull through this time. At the autopsy the kidneys presented the appearance ordinarily known as surgical kidney. The left cut through the prostate was moderate in extent, and the right side was nicked to the depth of a quarter of an inch, and there was none of the evisceration of the gland so often seen after lithotomy, where a very great amount of traction has been made. There was evidence of compound inflammatory action in the bladder, which had extended up the ureters, concentrating itself more in the right kidney, where were seen two cavities filled with blood, but not containing pus. At the apex of one of the kidneys was a large cyst containing fluid in the larger proportion, and in a lesser proportion, a thick layer of degenerated pus. In other words, it and other old cheesy masses showed evidences of what Moxon had before alluded to, of the possibility of recovery from surgical kidney.

DR. POST asked Dr. Weir if he experienced any difficulty in introducing the large rectangular staff.

DR. WEIR replied that he did not in this case, but that in one or two cases previously there had been some difficulty.

SLIDING APPARATUS FOR MAKING EXTENSION IN FRACTURE OF THE FEMUR.

DR. W. S. HALSTED presented a modified Esmarch-Volkmann apparatus, which served the purpose better than those used in most of the hospitals. One of the objections to the Esmarch-Volkmann apparatus, was that it was too broad, and thus interferred with the sound leg of the patient. Again, that it was apt to jump the track. The modified apparatus which he presented was little wider than one's leg (the bed-piece being of the same size as the leg-piece), and could not become disarranged by the patient, or obstructed by the bedclothes. Furthermore, as it represented an inclined plane the knee is not at all or only slightly flexed. After the apparatus was padded it was unnecessary to bandage the limb to the leg-piece. By means of tapes the padding, which consisted simply of a folded blanket, could be raised so as to make a cushion for the tendo-Achillis. In order to prevent eversion, if any tendency to it existed, the foot was tied to the stationary vertical foot-piece, not by means of a bandage tightly over the dorsum of the foot, but by a piece of flannel stitched to the cover of the sole of the foot, and in that manner pressure over the dorsum was distributed equally. In addition, there was an improvement upon the movable horizontal foot-piece, ordinarily employed in the extension apparatus, by which it always retained a position at right angles to the long axis of the leg.

DR. POST remarked that for some time past it had seemed to him that the entire principle involved in Volkmann's apparatus was erroneous. He believed that, instead of having the railroad arrangement upon which the limb might move freely, it was better to have the limb rest upon the bed, for the sake of securing additional friction, which would assist in maintaining extension, rather than placing it upon a sliding apparatus that allowed a constant antagonism between the muscles drawing the limb up and a weight and pulley drawing it down. He believed that this objection was not merely theoretical. He remembered one or two cases, in the Presbyterian Hospital, where the result in the use of Volkmann's apparatus was quite unsatisfactory, until the railroad arrangement was abandoned, and he availed himself of the friction which assisted the action of the weight and pulley in maintaining the length of the limb, while it was lying immediately upon the bed. Of course, one can in some instances completely nullify the action of the muscles by a sufficiently heavy weight, but if you have the support of friction a smaller weight may be sufficient.

DR. G. A. PETERS said that by keeping the limb upon the bed the patient was prevented from changing position. The Volkmann apparatus enabled him to move about somewhat.

DR. POST remarked that, perhaps, the Volkmann apparatus might be to the comfort of the patient, but he believed it partially defeated the aim of the treatment. He doubted if the practical results were as good as those obtained by the other method.

DR. PETERS thought that as good results had been obtained by the Volkmann apparatus as had been obtained without it.

DR. WEIR said that he should hardly like to have the statements made by Dr. Post pass without notice. He thought that with the weight and pulley not only was traction to be made on the limb, but the friction of the limb on the bed was to be overcome, and that the influence of the friction was to a great extent obviated in the Volkmann apparatus. He had found it unnecessary with the sliding apparatus to use nearly so heavy weights as when the limb was resting upon the bed. Another advantage in the Volkmann apparatus, which did not obtain in the use of the old extension apparatus, with the limb lying upon the bed, was the ability to correct the tendency to eversion of the foot, which had heretofore been extremely difficult to avoid. According to his own experience, until Volkmann's apparatus had been employed by him, he had not been able to satisfactorily meet this tendency. Besides, patients were more comfortable while being treated by the Volkmann than by the use of the ordinary weight and pulley.

DR. POST said that he approved of the upper story of the Volkmann apparatus, but objected to the freedom of motion permitted by the lower story. His belief was that the hands of the surgeon were the proper implements with which to draw the limb in place, and not the weight and pulley, the latter being simply adjusted to maintain the limb in position where the surgeon had placed it, and not have it placed between two antagonizing forces.

DR. STIMSON asked if the hands of the surgeon were not often insufficient to bring the limb down to its proper position.

DR. POST did not think that there was any difficulty in this direction.

DR. STIMSON thought that Dr. Post's experience had not been that of others.

DR. HALSTED thought it was difficult to estimate, by the old method, how much weight was necessary, for the reason that the patient may have his heel implanted in the yielding bed, or possibly the bedclothes wrinkled up under the limb, so as to take off the weight. He was also convinced that, in many cases, the long side-splint could not prevent eversion.

SARCOMA IN THE MUSCULAR PLANES OF THE THIGH, REMOVAL OF THE TUMOR, SECONDARY HEMORRHAGE, LIGATION OF THE FEMORAL ARTERY.

DR. POST narrated a case as follows, which had some relation to the subject of the paper read by Dr. Peters.

A week ago, last Wednesday, he operated upon a tumor of the thigh which was regarded as sarcomatous. He had not yet received the report from the pathologist of the hospital concerning its character. The disease was of about two years' standing, and occurred in a patient who was about forty-five years of age. Eighteen months ago he was in Havana, and a Spanish surgeon removed a tumor from the anterior part of the thigh near the knee. It was represented to be about the size of a man's fist. Soon afterward the tumor began to grow again, and when the patient came under Dr. Post's observation, there was a tumor extending from the knee nearly half-way to the hip, and occupying the anterior semi-circumference of the thigh. It was uncertain whether it was connected with the periosteum or not. There was a certain amount of motion which, by some of the surgeons, was regarded as flexion of the tumor upon itself. His own preference with regard to the treatment of the growth was that the limb should be amputated, but his colleagues preferred that an effort should be made to excise the tumor. After having applied an Esmarch bandage, he made a free incision very nearly the entire length of the tumor, reaching the rectus muscle, which he divided freely, and encountering a portion of the tumor which was somewhat distinct from the rest of the mass, and was so encapsulated that he could readily enucleate it. The great mass of the tumor was situated deeper among the tissues of the thigh, but it was not connected with the periosteum. In removing it, it was necessary to clip away portions of the adjacent muscles, and finally he succeeded in removing apparently the entire mass. Arrangements were made for proper drainage, and the wound was closed. The drainage-tube extended the entire length of the wound, coming out at the lower part. The drainage-tube was removed on the second day and the wound apparently pursued a favorable course, and there was no evidence of any want of reparative power. For the first two or three days the patient's temperature was somewhat elevated, 102° F. being the highest, and then it became normal. At the end of a week, finding that there was almost complete union of the edges of the wound, and a discharge of matter only through the opening at the upper part, he removed all the sutures and ligatures. That night, exactly a week after the operation, he was called up to see the patient on account of secondary hemorrhage. When he arrived the house-surgeon had opened the wound, and had tied several bloodvessels without controlling the hemorrhage. Firm pressure was being made in the groin when he reached the hospital, and he found the patient very much blanched, the pulse feeble, and he believed it to be hazardous to attempt, in the midst of such an extensive wound to lay it open and search for a bleeding vessel. Accordingly, he tied the femoral artery and there was no return of hemorrhage. The wound has been left open and is granulating, and the patient is doing well. There is a strong probability that the morbid growth will recur.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, March 1, 1883.

THE PRESIDENT, R. A. CLEEMANN, M.D., IN THE CHAIR.

DR. W. GOODELL presented the specimens and reported a case of

DOUBLE ENUCLEATION OF UTERINE FIBROIDS.

Mrs. B., a Hebrew lady, aged 38, and the mother of five children, the youngest five years old, began early in 1880 to have menorrhagia and difficult micturition. Later, her physician, Dr. A. H. McAdam, discovered a uterine fibroid. In January, 1881, Dr. Goodell was called in to see her. He confirmed the diagnosis and found a fibroid in the anterior wall of the womb, bulging out the anterior lip of the cervix, which was greatly hypertrophied, but not at all enlarging the os. The sound gave a measurement of six inches. As all remedial measures wholly failed, he admitted her into his private hospital, and, on February 6, cut into the tumor by means of Adams' subcutaneous saw, and by enucleation removed most of it. A month later, the fragment left behind descended low enough to be removed without difficulty. The tumor weighed not quite two pounds. At the time of this last operation, a small fibroid was discovered in the posterior wall of the womb, but it was too high up to be attacked. Her convalescence was prompt, and her monthly flux became natural. On October 6, the sound gave a measurement of only three inches, and she felt well. But in the following March she again sought his advice for a return of the menorrhagia. A fibroid was now bulging out the posterior lip of the cervix but not expanding the os. The uterine cavity measured five inches. As all remedies again failed, enucleation was once more proposed, and, on February 28, 1883, the operation was performed for the second time. The posterior lip of the cervix was cut open by the saw without invading the uterine cavity, and after an hour's hard work, a tumor weighing one and a half pound was taken away in fragments. Several very beautiful and perfect fibroids as large as a pigeon's egg were also removed. They were attached to the capsule of the mother tumor merely by loose connective tissue. About a pint of blood was lost during the operation, but after the removal of the tumor the hemorrhage ceased, and the cavity left behind was not tamponed. The patient is doing very well, although the shock was somewhat profound.

In commenting upon this case, Dr. Goodell remarked that the to-and-fro linear movement of the saw made it a very efficient instrument for working in narrow channels, and that it had the further merit of lessening the amount of hemorrhage. He now used no other instrument for incising the capsule of fibroid tumors. The history of this unique case had somewhat shaken his confidence in the operation of enucleation, because since the womb is affected usually with multiple fibroids, some one of these must invariably be left behind, and a second operation may become needful. He believed that in these cases oöphorectomy, as a safer and more sure remedy, had a future before it. He had, in fact, performed the operation four days ago on a lady who was so feeble from prolonged hemorrhage, that he did not dare to remove the fibroid by enucleation, which is a more prolonged operation, and attended by

a greater loss of blood. She was doing very well indeed. For the same reason, not daring to enucleate, he had early last year removed both ovaries for a bleeding fibroid; but after a remission of several months, the hemorrhage returned, and he will probably have to perform enucleation or hysterectomy.

DR. B. F. BAER inquired if the case in which hemorrhage returned after oöphorectomy was not of the submucous variety? Ought not the operation to be limited to the interstitial and subperitoneal varieties, where enucleation is not possible? In one case reported by Dr. Byford, of Chicago, a uterine (submucous) fibroid went on increasing and hemorrhage continued after oöphorectomy.

DR. GOODELL, from *à priori* reasoning, would expect less favorable results in submucous tumors, as they are more like polypi in their characters, and would be more likely to continue to bleed. The case referred to, in which oöphorectomy had failed, was of the submucous type, and could have been removed by division of the mucous membrane and enucleation had the patient's condition permitted it.

DR. B. F. BAER narrated the history of a case in which

INDUCTION OF PREMATURE LABOR, FOR THE RELIEF OF SUPPRESSION OF URINE.

was considered necessary. The case occurred in the practice of Drs. Marcy and Mecray, of Cape May, N. J. About the sixth month of pregnancy a general œdema was noticed, and the urine contained considerable albumen and a few casts. The amount of urine passed diminished rapidly, while the proportion of albumen increased, and the patient became weak and anæmic. Every means was tried to increase the quantity of urine, but without avail. Among the remedies used were a wide range of diuretics and hydragogue cathartics, with Basham's mixture. A sudden suppression of urine occurred at eight months, and but four ounces were passed in forty-eight hours, this became solid when heated; headache and spots before the eyes were now added to the other symptoms, a grumous discharge from the uterus had been noticed for a week, and convulsions seemed threatening. Dr. Baer was called in consultation, and he agreed with them as to the advisability of inducing premature labor. A No. 9 flexible catheter was warmed and softened, and was, after great difficulty, introduced between the membranes and the anterior wall of the uterus. The cervix uteri had been lacerated in a previous labor and was hard and small. Pains of a natural character followed immediately upon the introduction of the catheter. After some hours the pulse became weak and the patient faint, the os was but slightly opened, and it was considered advisable to administer stimulants, and the use of Barnes' dilators and the Hodge forceps, a dead child was speedily extracted. The latter had been alive in the morning. Four hours after delivery urine was secreted, and in two days the albumen had entirely disappeared. The patient recovered.

DR. D. F. WILLARD reported a case of

INDUCED PREMATURE LABOR NECESSITATED BY GREAT ŒDEMA OF THE LABIA MINORA.

The patient, probably over forty years of age, had been married about one year, and was pregnant with her first child. She suffered from headache, her feet and eyelids were swollen and her urine showed one-sixth albumen and contained casts and blood corpuscles. Basham's mixture, diuretics of every kind, diaphoretics, hot-air baths, hydragogue cathartics, and tonics were used, without a satisfactory result. Digitalis infusion and jaborandi alone gave a very temporary relief. The patient soon after her first visit called attention to the condition of the labia minora, which were found to be enormously swollen, shining, tense, and pitting on pressure. The urine amounted to from fifteen to thirty ounces per day and steadily decreased in quantity. The œdema of other portions of the body decreased under the use of digitalis, but that of the labia increased. The patient could lie only upon her back with the knees drawn up and as widely extended as possible; the pain was great and constant. Lancet punctures were made with temporary relief. The patient was steadily failing; her pulse was 150 per minute. An erysipelatous blush made its appearance and rapidly spread to the abdomen and thighs. Premature extraction of the child offered the only chance, and was at once performed. Gestation had reached eight months. It was a difficult task, as the labia were five inches in depth. Barnes's dilators and the Hodge forceps were used, and delivery accomplished in two hours. The child was dead, and the mother died three hours later.

CORRESPONDENCE.

THE BALTIMORE MEDICAL COLLEGE.

To the Editor of THE MEDICAL NEWS.

SIR: There is an item in your issue of the 3d instant in regard to the Baltimore Medical College, that is calculated to affect the standing of the school, where its character is not well known, *i. e.*, should silence be observed in regard to the matter to which it alludes. The facts in the case are briefly as follows, viz.: Dr. N. Hamilton Baker, a graduate of the Baltimore Medical College, of 1882, presented his diploma (so he writes) to the State Board of Health of West Virginia, but was required to stand an examination as a pre-requisite to practising his profession in that State. He submitted accordingly and passed a satisfactory examination before that Board, and paid the examiners ten dollars as their fee! It will be seen that the Board endorsed, by its action, the judgment of the Baltimore Medical College as to the qualifications of Dr. Baker for the practice of medicine! It has long been the custom of the United States Army and Navy Medical Examining Boards to pass those *only* who *are* qualified to enter the medical service of our common country, without regard to period of study, or whether they are M.D.'s or not; and the State Board of Health of West Virginia acts upon a similar principle, I presume; at least it should do so.

The Baltimore Medical College regards *merit* as the standard of admission to the Doctorate, and is using great effort to *elevate* the profession by conferring the degree of M.D. upon those only who are deemed *worthy* of it. Its sessions of seven and a half months is a move that meets the approval of its friends, and students are earnestly invited to attend upon these courses regularly. But, as there are no means of forcing them to do so, the standard for the degree of M.D. has been made so high that the applicant for it *must* be qualified to discharge the duties of the profession ere it can be received.

I will only remark in concluding, all that is necessary to be said in justification of the Baltimore Medical College in the discharge of its duty to its friends and the public, that it wants no better endorsement of its teaching, and its ability to decide upon the fitness of its graduates for the practice of medicine than the fact that they have been *invariably successful* in passing their examinations in a satisfactory manner to *all* the legally authorized Medical Boards before which they have appeared.

I have the honor to subscribe myself, very respectfully,

Your ob't servant,

HARVEY L. BYRD, M.D.

NEWS ITEMS.

WASHINGTON.

(From our Special Correspondent.)

The Army Appropriation Bill, as finally settled by conference committee and passed, allows $10,000 for the Army Medical Museum and Library, as usual; the Senate amendment having been withdrawn.

The bill limits to seventy-five the number of contract surgeons to be employed after July 1st.

The Sundry Civil Appropriation Bill, as passed, provides for the publication of Vol. V. of the *Index Catalogue*.

On the last day of February, Mr. Shallenberger, from the Committee on Public Buildings and Grounds, reported a bill to provide a fire-proof building for the Army Medical Department, together with a report in which the necessity for such a building is clearly set forth. The bill came too late in the session to be acted on, and the work must be done over again in the next Congress; nevertheless, the action of the committee marks progress, and the medical profession is indebted to Mr. Shallenberger for the interest which he has taken in the matter. The details of the report will be given hereafter.

CANADA.

(From our Special Correspondent.)

Removal of Uterus with Fibroids.—At the last meeting of the Medico-Chirurgical Society of Montreal, S. Trenholme showed a large fibroid of the uterus which he had removed, with that organ, from a woman aged 39. The patient lived for five days, and died of exhaustion from uncontrollable vomiting. The uterus was cut off at the cervix; the body was flattened on the tumor, and a sound could be passed for nearly seven inches. The mass weighed twenty-five pounds.

The Yea and Nay Vote on the New York Code.—Through the courtesy of Dr. E. R. Squibb, we have received advance proofs of the March issue of the *Ephemeris*, in which appears a very interesting analysis of the action of the New York State Medical Society at its late meeting, in reference to the Code of Ethics, from which we note the following extract:

"It becomes very evident that this question is still unsettled, and is far from being settled, because on the one hand the victorious party are not satisfied with their victory, but propose to move on to greater victory by the abolition of their present code, and of all restrictions, while the vanquished are dissatisfied principally because their lost cause was a good cause on the side of morality and rectitude, and because it was lost in contravention of the expressed will of a majority of the County Medical Societies, and of the expressed opinion and judgment of nearly the entire profession of the nation outside this State."

We are also indebted to the *Ephemeris* for a list and analysis of the yea and nay vote on the motion to repeal the new code, from which we compile the following table, in which the members are grouped by counties, for the information of our readers. The names of delegates are printed in Roman, and of *permanent members* in Italics. Beneath the name of each county society is recorded the vote which represents the previous action of the county society on this question, and the number of its delegates and permanent members. The reader can thus see for himself how fully and fairly the expressed sentiment of each county society has been represented in the vote to reject the New Code.

Albany County.

Nay (Four Delegates; Sixteen Permanent Members).

Yea.	*Nay.*
J. W. Moore	F. C. Curtis

An analysis of this vote shows that of 136 authorized *delegates* 103 were present, and of these 53 voted yea and 50 nay. Of 255 *permanent members* 101 were present, and of these 46 voted yea and 55 nay.

During the past year, of the 59 county societies 37 voted against the New Code, and 5 endorsed it, and 17 are not known to have taken any formal action in the matter.

In commenting on this analysis the *Ephemeris* says:

"Of the 59 County Societies, 42 at least are known to have ranged themselves on one side or the other of this issue; 37 have taken positions equivalent to voting yea, and 5 equivalent to voting nay, on these resolutions. Of the 42 societies, 35 were represented by delegates at this meeting. The delegates of 29 societies sustained the action of their societies, and those of 6 societies reversed the action of their constituent bodies.

"Of the 42 societies, 22 were present and voting by permanent member representation. The permanent members from 12 of these societies sustained the action of their societies, and from 10 they reversed the action of their societies.

"Taking the delegates and permanent members together in a majority county vote, the total representatives of 23 counties sustained the action of their societies. Those of 8 counties reversed the action of their societies, while those of 7 counties gave tie votes.

"This shows that in many instances the delegates, having practically no Code of Ethics, felt at liberty to defeat the majority in the societies represented, or misrepresented, by them. Under such a system the question of how primary organizations can possibly be

represented in secondary representative organizations in the absence of a Code of Ethics seems to be an unsolved problem in the representative form of self-government by majority rule. In one known instance a delegate voted against his individual convictions in order to support the majority vote of the Society which sent him. And in another instance the delegate as deliberately voted against the majority in the Society which sent him, and, therefore, defeated that majority, and each of these delegates represented a county.

"It can hardly fail to interest any one who looks over this table to see the full attendance and solid voting of Albany and New York counties; and it is equally interesting to see what the result would have been with these two counties left out, or with room in them for the same diversity of opinion shown in other counties."

WHAT IS SAID OF IT.—The success of the New Code, as so far obtained, is most likely attributable to the indefatigable efforts of a few prominent specialists, who alone will be benefited pecuniarly by the bridging of the chasm heretofore existing between regular medicine and charlatanism.—*Nashville Journal of Medicine and Surgery.*

Notwithstanding all the touching and beautiful talk in the New York County and State Medical Societies in regard to the matter of "humanity" and the "elevation of the standing of the profession," it would at first sight seem rather a significant fact that the new code agitation was entirely inaugurated by specialists, and that every man who has taken at all an active part in securing its adoption and preventing its repeal is a specialist. It is probably, however, only a curious coincidence that the specialists are the ones who must necessarily derive the largest amount of pecuniary benefit from consulting with all "legally qualified practitioners of medicine." Among legally qualified practitioners our new Code friends in New York will, no doubt, be much pleased to learn that they may now have the opportunity of meeting in consultation the noble and good Dr. Buchanan, lately of Philadelphia, who, we are informed on excellent authority, is now a registered physician in their city, and who, having graduated from Moyamensing, as well as a medical college, must have had special opportunities of study and experience, which the profession and public ought not to be slow in availing themselves of.—*Boston Medical and Surgical Journal.*

THE NEW YORK POLYCLINIC has had one hundred and twelve physicians studying in the various classes since November 7th last; and two thousand five hundred patients have been treated in the Polyclinic Building within this period.

MEDICAL DEPARTMENT OF THE ARKANSAS INDUSTRIAL UNIVERSITY.—The Annual Commencement of this institution was held at Little Rock, on February 21st, and the degree of M.D. was conferred on four candidates.

THE COUNCILLORS OF THE MASSACHUSETTS MEDICAL SOCIETY AND THE COLUMBUS MEDICAL COLLEGE.—In accordance with the recommendation of the Committee on Medical Diplomas, it was voted that the Columbus Medical College, of Columbus, Ohio, be dropped from the list of medical colleges whose diplomas are recognized for admission to the Society

THE ATLANTA MEDICAL COLLEGE.—The twenty-fifth annual commencement of this school was held on the 28th of February. The Rector, Dr. J. A. Gray, reported that there had been in actual attendance at this session of the college 126 students, representing ten different States, as follows: Georgia 94, Alabama 12, Texas 5, South Carolina 5, North Carolina 4, Arkansas 2, Mississippi 1, Louisiana 1, Florida 1, Vermont 1. Of this number 66 were first course students, and 60 were second course. Of these, 39 composed the graduating class. After the conferring of the degree, ex-Chief Justice Bleckley made a few remarks, and then recited an original poem on "Patients and Patience," which will be found in another column.

FRENCH OPHTHALMOLOGICAL SOCIETY.—A Society of Ophthalmologists has recently been formed in France, and has just held its first session under the presidency of M. Dufour, of Lausanne.

MEDICAL EDUCATION IN GERMANY.—The Association of Physicians of Munich has recently addressed a petition to the Federal Council, asking an extension of the necessary period of study from four to five years.

THE TWELFTH CONGRESS OF THE GERMAN SURGICAL ASSOCIATION will be held in Berlin, from April 4th to 7th, under the presidency of Prof. von Langenbeck.

JOHNS HOPKINS HOSPITAL.—The Annual Report of the Building Committee of the Johns Hopkins Hospital, for 1882, has been published. The work during this year alone has been the completion of exterior work on the Administration Building, the erection of the amphitheatre, dispensary, autopsy building, and laundry—together with the grading, draining, etc., of the grounds—all at a cost of $142,976.83. The income from the Hospital Trust Fund for the year, less taxes, was $153,419.80. The total amount expended upon the hospital to January, 1883, is $1,304,167.31. Of this amount the work upon fourteen buildings has cost $883,484.96, the lot $279,522.06, and grading, etc., $142,160 29. The building estimate for the ensuing year is $205,450.

PREVENTION OF SCARLET FEVER.—In view of the recent prevalence of scarlet fever in Hartford, New Britain, Meriden, Middletown, New Haven, and other towns in Connecticut, the State Board of Health has issued a circular (No. 8) on the prevention and restriction of this disease. Isolation until six or eight weeks after convalescence has been fairly established, disinfection during treatment, and fumigation by burning sulphur at the conclusion of the case, are the measures recommended. It is urged that a hospital for contagious diseases would save many lives, as in crowded tenement houses isolation is out of the question. "The idea, at first, is not a popular one, but once established, its powers for good will dispel all objections." Legal enactment is considered desirable to secure the abolition of public funerals in cases of death from this fever. The disinfectants recommended are:

1. For cotton and linen goods, for washing the hands, and almost all uses, sulphate of zinc, four ounces; common salt, two ounces; water, a gallon. Double the strength should be used about the bodies of those dying from scarlet fever.

2. Copperas, a pound and a half to the gallon of water, for sewers, drains, and excreta.

3. Lerned's disinfectant possesses the advantage of giving off non-stifling odors, and can be used to fumigate halls, entries, and rooms while occupied. It is considered effectual, and has been largely used. It does not take the place of sulphur for *complete* fumigation.

An Anti-vivisection Meeting at Manchester.—"The hard-hearted men of science" routed the English anti-vivisectionists, at a recent meeting at Manchester of the local branch of the International Society for the Suppression of Vivisection. The chief speaker, a clergyman, had launched the usual declaration against vivisection, when Prof. Gamgee, Dr. Stocks, and Mr. Dreschfeld arose and so changed the current of public opinion that the anti-vivisectionists found themselves almost deserted. and their resolutions, condemning vivisection under any circumstances, were rejected amid cheers by an overwhelming majority.

German Criticism.—Under the heading of "*Esprit Critique des Allemands*," the *Revue de Thérapeutique* draws a parallel between the criticism of Esmarch on the conduct of the case of President Garfield, and the comments on the treatment of Gambetta by Prof. Niemeyer, who is said to have called the French surgeons a pack of blockheads (*ânes bâtés*), and that Gambetta's wound was not fatal, but that he died of his physicians.

Nutritive Properties of Rice.—The increase in the consumption of rice has lately attracted the attention of several men of science in Germany, and, amongst other investigations, an attempt has been made by Prof. Voit to discover the relative capacity which various forms of nourishment possess of being incorporated into the system. He has drawn up the following table of the percentage which remains in the body, and of that which leaves it:

	Percentage incorporated.	Percentage which is not retained.
Meat,	96.7	3.3
Rice,	96.1	3.9
Eggs,	94.8	5.2
White bread,	94.4	5.6
Maize,	93.3	6.7
Potatoes,	90.7	9.3
Milk,	88.9	11.1
Black bread,	88.5	11.5

According to these results (the *Bremer Handelsblatt* remarks), meat and rice leave the smallest amount of residuum, and occasion the smallest excessive exertion to the digestion, and in fact introduce the minimum quantity of ballast into the human frame. Dr. König, of Münster, considers that the fact of large masses of population living on rice is easily accounted for, and in summing up the information collected upon the subject, Prof. Voit remarks that potatoes, when consumed in excessive quantity, fail to nourish the frame effectively, make the blood watery, and render the muscles weak. Apart from the subject dealt with in the table drawn up by Prof. Voit, the question of the relative nutritive value of rice and potatoes has been investigated by Dr. König, who is of opinion that if similar quantities of both articles are compared, the former possesses four times the value of the latter in really nutritive properties. It is also remarked that the introduction of rice as a substitute for potatoes is facilitated by the fact that no such variation takes place in its quality as is the case with the potato, which is liable to be materially influenced by the effects of unfavorable weather.—*Lancet*, Dec. 30, 1882.

The Public Health in Connecticut.—The secretary of the State Board of Health in his report for January, just issued, states that the death-rate of January, 1883, compares unfavorably with that of the same month for the three preceding years. The presence of scarlet fever in many places increases the death-rate, to which also pneumonia contributes more than the usual proportion, although usually one of the prominent diseases of the month. Catarrhal diseases, colds, and the milder forms of bronchitis have been unusually prevalent; the changeable weather probably induces carelessness. There have also been quite a number of cases of broncho-pneumonia, so called, which begins as a case of bronchitis, often not severe, and giving no indications of danger until symptoms of a severe type of lung fever supervene without warning, often involving both lungs and terminating fatally. This is an insidious and dangerous disease. In Hartford scarlet fever was followed by diphtheria and croup, which have been very fatal. There have been no deaths from typhoid fever nor from malarial diseases in Hartford; indeed, malarial diseases are apparently decreasing quite rapidly in this immediate vicinity. The mild winter, however, is favorable for an increase when warm weather ensues.

In New Haven whooping-cough has been almost if not quite epidemic, causing ten deaths, which indicates either a much greater prevalence than the same number of deaths would in most diseases—for it is seldom fatal—or else an unusually severe type. Measles have also been very prevalent there, and also in several towns in that region. There have been a few cases in Hartford.

Scarlet fever has been prevalent quite extensively in Hartford, while it has decreased very decidedly during the month in New Britain and Meriden, also in Middletown; it has apparently just reached New Haven, which reports but four deaths, although there had been occasional cases from time to time. It has extended over considerable territory, and the cases have been quite numerous. The type has been apparently much more severe in the cities, where the sanitary conditions of the children would naturally be worse in many instances. It is reported as still prevalent in Suffield, but commencing to decrease—half the estimated number of cases that there were in December, when it was epidemic and the cases severer. It is also reported from Plainville, Avon, North and South Manchester, Talcottville, Stafford, South Britain, Haddam, Hampton, and Ansonia. It is apparently advancing, as new territory is reported each month.

Measles has been unusually prevalent in Thomaston, where there has been a sweeping epidemic. Over fifty cases were reported in January. Bronchial complications were frequent. It has not been unusually fatal; but few deaths are reported anywhere. It has been prevalent in New Haven and Ansonia, and many towns in the southwestern part of the State, often, as in New Haven and Ansonia, accompanied with whooping-cough. Measles is also reported from South Manchester, Plainville, and Plymouth.

Diphtheria is reported from several towns, but in none as epidemic or unusually frequent.

Health in Michigan.—Reports to the State Board of Health, for the week ending February 24, 1883, indicate that intermittent fever and pneumonia have considerably increased; that influenza, tonsillitis, and whooping-cough have increased in area of prevalence. There was no marked decrease in any disease reported.

Including reports by regular observers and by others, diphtheria and scarlet fever were each reported present during the week ending February 24th, and since, at sixteen places, and measles at eleven places. One case of smallpox was reported at Detroit, February 24th.

The Louisiana State Board of Health and the New Orleans Auxiliary Sanitary Association.—In December of last year the State Board of Health of Louisiana adopted resolutions to the effect that the period of usefulness of the Auxiliary Sanitary Associa-

tion had passed, in that it had ceased to be auxiliary in attempting to become supercidiary. This action was brought about by a well-meant effort on the part of the Association to have more active measures adopted for the suppression of smallpox, which had then made its appearance in the city. That such measures were required, is shown by the progression of the disease during the first eight weeks of the present year. The mortality during this period has amounted to 187, the weekly figures having been as follows: 11, 13, 25, 13, 33, 31, 21 and 40.

Recently, a petition of citizens has been presented to the Board, having for its object a repeal of the resolutions in relation to the Sanitary Association. At its meeting, on March 1st, the Board considered this, and adopted the following:

Resolved, That the State Board of Health of Louisiana will agree to rescind said resolutions when the New Orleans Auxiliary Sanitary Association shall have adopted the following:

1. The repeal of the resolutions, adopted by it, indorsing the National Board of Health, and urging its perpetuation.

2. The adoption of a resolution indorsing and sustaining Louisiana's legal health representative and guardian, the State Board of Health, to which they profess to be auxiliary.

JAPANESE HEALTH REPORTS.—The weekly reports of the health authorities of the city and province of Nangasaki, Japan, compare favorably with those issued by many of the municipalities which have been reared by Indo-European civilization. They are neatly ruled and printed in blue ink, on thin, strong paper, and the hieroglyphics, which run along the upper and right hand borders, with those, presumably indicating number, inserted in the columns, pique the curiosity of our western and uncivilized eyes to know what is meant by them. Fortunately we have also received translations, by which we find that the health officer in Japan, or at least in this province, reports concerning certain diseases, to wit., cholera, smallpox, diarrhœa, paralysis, nerve fever, and fever, the number of cases in each district remaining on hand from last report, taken sick since then, recovered, died, and remaining under treatment, the entries under each heading being double, and specifying the sex of the patients. The totals are given at the foot of the page, and an appendix furnishes the status of each disease from some starting-point or previous date, which does not appear in the translation, giving the totals under the various headings since that date.

When our health officers get as far as this in observing and recording the movement of disease, we shall have reason to congratulate them.

NOTES AND QUERIES.

CASES OF TRANSFUSION OF BLOOD.

DR. THOMAS G. MORTON, of Philadelphia, is desirous of securing the histories of all unpublished cases of transfusion of blood which have occurred in this country; and on application will be happy to furnish blanks for their registration.

PORRO OPERATIONS IN ITALY.

IN our last number, under this heading, we remarked, that "it would be interesting to know how many of the children survived." To this query, Dr. R. P. Harris replies. There have been, as far as published in the journals of Italy, 43 Porro operations in that country, saving 18 women and 33 children. The last 28 operations, dating from May 16, 1879, saved 14 women, or 50 per cent This may be considered a fair estimate of the mortality of the operation at the present time in Italy, in making a prospective calculation of the risk. The earlier the operation, after labor has fairly commenced, the greater the hope of success.

"PATIENTS AND PATIENCE."

A POEM read before the Graduating Class of 1883, of the Atlanta Medical College, by Ex-Chief Justice Logan E. Bleckley.

The question of questions is now to be met!
The practical question, how patients to get?
The patience of Job, since Job has retired,
May either be purchased or borrowed or hired;
The first thing to ponder—to ponder and probe,
Is, how to acquire the patience of Job.
When he was in practice his patience was much;
And every young doctor needs plenty of such—
The patience to labor, to learn, and to wait,
To suffer, endeavor, endure, and be great.
Job's practice was simple; his treatment was what?
Some ashes, and scraping with pieces of pot;
Then silence a week; then cursing a day;
Then railing at everything others could say.
How unscientific! and yet, as we read,
No practice than his could better succeed.
The patient recovered—remained on the stage
Through four generations, and died of old age.
The fee was a fortune! He got, we are told,
Unlimited money and ear-rings of gold—
With camels, and asses, and oxen, and sheep,
By thousands—much more than his pastures would keep.
Ah, Job had the patience, the time, and the place!
His riches, remember, were all for one case.
Whatever you covet, or merit, or earn,
Depend upon patience to make the return.
Your science and learning, you latest M.D.'s,
Your medals and honors, diplomas, degrees,—
Why, Job's were as nothing contrasted with these,
But they never will bring in such fabulous fees.
If doctors have patience, the patients will come;
Some cannot have all, but they all may have some;
If patients have patience, 'tis safe to foretell
That twelve to the dozen are sure to get well.
Whoever says "patients" has "patience" to say:
By name and by nature, in both there is pay.
That like will cure like, is the hint that peeps through:
"*Similia similibus curantur*," often is true.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 26 TO MARCH 5, 1883.

BURTON, HENRY G., *Captain and Assistant Surgeon.*—The leave of absence granted October 2, 1882, is extended two months. —*Par. 2, S. O. 49, A. G. O., February* 28, 1883.

CALDWELL, D. G., *Captain and Asistant Surgeon.*—To be relieved from duty at Fort Fred. Steele, Wyoming Territory, and will report in person to the commanding officer Fort Laramie, Wyoming Territory, for assignment to duty at that post.—*S. O. 23, Department of the Platte, February* 27, 1883.

PAULDING, H. O., *Captain and Assistant Surgeon.*—The leave of absence granted in S. O. 11, Department of the Platte, January 27, 1883, is extended twenty days.—*S. O. 23, Military Division of the Missouri, March* 2, 1883.

FESSON, LOUIS S., *Captain and Assistant Surgeon.*—To be relieved from duty at Fort Clark, Texas, and assigned to duty at Fort Ringgold, Texas, as Post Surgeon.—*Par. 5, S. O. 20, Department of Texas, February* 21, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

ORIGINAL LECTURES.

ON THE TREATMENT OF DISEASES OF THE NERVOUS SYSTEM.[1]

BY PROF. DUJARDIN-BEAUMETZ,

MEMBER OF THE ACADEMY OF MEDICINE, PHYSICIAN TO THE HOSPITAL ST. ANTOINE, PARIS.

THE NERVOUS SYSTEM FROM A THERAPEUTIC STANDPOINT.

GENTLEMEN: I do not make light of or conceal the difficulties of the task which I enter upon to-day. The study of the treatment of nervous diseases is, in fact, one of the most delicate and most difficult, for to the hygienic and medicinal measures with which we have thus far been occupied, we must add a certain influence of a moral kind, exerted by the physician, an influence altogether personal, which plays often a preponderating part, and which constitutes a veritable moral therapeutic agency, respecting which it is not at all easy to furnish precise and exact data. That obscurity and that hesitation which attend us at every step in the treatment of nervous diseases, result from a number of circumstances. Although, during the last twenty years, the study of affections of the cerebro-spinal axis has made immense progress, and this especially in our own country, under the powerful and sage impulsion which Prof. Charcot has given to the School of the Salpêtriére, there exists still, unhappily, numerous lacunæ in this study. Physiology itself, which has accumulated, for a great many years past, an innumerable number of works on this special subject, is far from having solved all the problems of the vital and physiological functions of the nervous system. As for therapeutics, it must be confessed that this department of medicine is still less advanced; not being able to base itself on positive physiological and pathological data, it has drifted about, having no guide but empiricism and tradition.

I believe it my duty, however, to show you in these lectures the office of the physician in diseases of the nervous system, and what he can accomplish in certain cases by sage and reasonable therapeutic measures. But that you may well understand the difficulty of the subject of which I am going to treat, and how fragile the physiological and therapeutical basis is on which rests the treatment of nervous diseases, I am going to devote this first lecture to the study of the nervous system from a therapeutic standpoint.

The nervous system, reduced to its simplest expression, may be represented by two elements, a nerve-cell and a conducting tube.

The nerve-cell, as you are aware, is composed of three parts: a nucleus, enclosing a nucleolus in its centre, a peripheral, homogeneous substance, and an excessively fine envelope. These cells present prolongations, more or less numerous, and their volume offers variable dimensions.

As for the nerve-tube, it possesses an investing membrane—the neurilemma. This neurilemma surrounds the nerve-fibrils, which are themselves constituted of three parts: an axis cylinder, continuation or prolongation of the cell; a transparent membrane, constituted by the myeline; and an external tunic.

As for the chemical composition of these substances, it has for its basis certain phosphorized oils, whose essential principle, according to Liebreich, is a neutral phosphorized body, which he has described under the name of *protagon*.

These cells and these nervous tubes, associated in divers ways, constitute the nervous system in its entirety. I do not purpose to enter into details of this structure; this is a point quite outside of my subject, and which would demand for its complete exposition, numerous lectures. But I desire, before going further, to draw a first conclusion from the several details into which I have just entered respecting the constitution of the nervous system. I refer to the application of phosphorized substances, and of phosphorus, to the treatment of diseases of the cerebro-spinal axis.

From the fact that nervous substance contains a large proportion of phosphorus, it is by no means demonstrated that the diseases of the nervous system, and in particular temporary perturbations of this system, such as those which constitute hysteria, for instance, are accompanied by a diminution of the phosphorus contained in the protagon. And even were this fact demonstrated, it would be necessary to prove that phosphorus, or phosphorized substances introduced by way of the stomach, are utilized for the nutrition of the nervous system; which is very doubtful. We encounter here (and shrouded in even greater obscurity) the same therapeutical problem which met us in the past, and which meets us to-day, respecting the action of ferruginous medicines. From the fact that iron is a constituent of the blood, we do not the better understand the *modus operandi* of chalybeate preparations. So we ought not to conclude, because phosphorus is an integral part of the nervous system, that therefore, *à priori*, the preparations of phosphorus are indicated in diseases of that system.

Seat of intelligence, sensibility, and movement, the nervous system plays a still more important part when we study its influence on nutrition throughout the entire animal series. The celebrated experimentation of Claude Bernard, in 1851, opened new and unlooked-for horizons respecting the *rôle* of the nervous system in the organism; and leaving one side all the discoveries which have flowed from this experimentation, I will consider only those which have a bearing on therapeutics.

Heretofore, in the study of medicinal substances, their action on the blood, and on the parenchyma of the viscera, was alone taken into account; it was thought that medicaments introduced into the economy modified the constitution of the blood, or even the tissue elements themselves, and from this double action their therapeutic and toxic effect was derived. The discovery of the vaso-motors, in showing us that the circulation, secretion, intimate nutrition of the tissues are under the dependence of special nerves—vaso-constrictors, vaso-dilators, trophic nerves—has considerably modified this experimental study, and even suggested the thought that henceforth the key to the great problem of the physiological and therapeutical action of the greater part of medicinal substances is to be found in the influence of these substances on the nervous system—on nerve-tubes and nerve-cells.

My duty now is to point out to you what are the positive facts pertaining to this subject, and what, unfortunately, are the too numerous points of uncertainty and obscurity.

[1] Translated, with permission of the author, from advance sheets, by E. P. Hurd, M.D., of Newburyport, Mass.

I cannot examine all the medicinal substances and acquaint you, for each one of them, with the positive and negative facts which are furnished us by experimental therapeutics, *àpropos* of their action on the elements of the nervous system.

This task would be immense, and would embrace therapeutics in its entirety. I have time only to consider briefly certain medicaments in their action on the cerebro-spinal or vaso-motor apparatus, and whose effects have been the most studied and are the best known.

Those medicaments which act on the cerebro-spinal axis, and whose effects are best known, are certainly the anæsthetics, which modify and alter, at a given moment, the functions of the nervous system. I propose here to examine, with reference to their modifying action on the nervous system, two substances—chloroform and alcohol.

Claude Bernard has given us a series of experimental researches on the action of chloroform, which are a model of their kind. In one fundamental experiment he shows us first of all, that chloroform cannot act unless it be absorbed by the blood and carried to the cerebro-spinal axis. I spoke of this last year when treating of the penetration of medicaments by the air passages, and will not return to it now. By repeated experiments he sought and obtained a solution of the second part of the problem which he set before himself, namely, what is the *rôle* respectively of the cerebrum and the spinal cord in this anæsthesia? Both are affected independently by anæsthetics; but the cerebrum, as Claude Bernard says, is the centre of centres; that is to say, when it is under the influence of chloroform, the anæsthesia generalizes itself over the whole economy, while, on the other hand, when the spinal cord alone is affected, the anæsthesia extends over only a limited zone of the organism.

By an attentive study of the phenomena which characterize the action of anæsthetics, the illustrious physiologist shows that the cerebro-spinal axis is not affected in all its parts at the same instant, and that, on the contrary, each one of them successively submits to the influence of the medicament. This order of succession is the following: The brain is first taken, and the consciousness of the ego is at once lost, but the spinal cord remains intact, and the reflex movements of the whole body persist. In a more intense degree of anæsthesia the spinal cord in its turn is overcome, but the medulla oblongata remains unharmed, presiding over the movements of circulation and respiration, which continue their function in a veritable cadaver, when every other sign of life has disappeared; the reflexes are abolished, anæsthesia is general, muscular collapse is absolute. But if you keep on increasing the dose of chloroform, the rachidian bulb is taken in its turn, and the animal succumbs; and in the interesting communication which he has lately made to the Academy of Medicine, Vulpian has shown us that if the rachidian bulb seems to be intact, it is nevertheless affected, and that in a chloroformed animal, it is only necessary to induce a slight nervous shock to suspend the functions of the medulla oblongata in its turn.[1]

By these experiments we see clearly set forth the part which pertains respectively to the circulation and to the nervous system in the action of the medicinal or toxic substance; the circulation bringing from the periphery to the nerve-centres the medicinal substance, and these, when affected by the medicament, generalizing the effect from the centre to the periphery. But this does not suffice; it is necessary to penetrate further into the subject, and demand what is the intimate action of chloroform on the nerve elements themselves. Claude Bernard has shown us by experiments of rigorous precision, that in the case of sensory nerves this momentary loss of their functions is absolutely analogous to what takes place when the sensory nerves succumb to abstraction of blood; or, if you prefer this statement, that troubles of sensibility manifest themselves at the periphery, while the action of the medicine is exerted on the centre (*i. e.*, the nerve-cells), in accordance with the law laid down by Claude Bernard, "the nervous element loses its properties by the extremity opposite to that where it is affected."

But what is the alteration of the nerve-cell produced by the contact of chloroform conveyed to it by the blood? Here we can only make hypotheses. The most probable is that which Claude Bernard has offered, viz., that chloroform causes an incomplete coagulation of the protoplasmic substance surrounding the cell-nucleus, that this coagulation is temporary, but that, under certain circumstances, it may be final.

The solution of the problem in therapeutics, which I have stated, is not yet complete, for there is another element of the nervous system which is to be taken into account, viz., the great sympathetic, which modifies, in its turn, the circulation, and especially that of the brain, and produces there that anæmia which is such a factor in the anæsthetic sleep, as well as in natural sleep, as Hammond and Durham were the first to show us. The effects, then, of anæsthetics may be partially explained by the action of chloroform on the ganglionic centres of the vaso-motor system.

What I have just said of chloroform, I may almost repeat, word for word, of alcohol. It also is carried by the circulation to the nerve-centres. Like chloroform, it disturbs, more or less, the action of the cerebro-spinal axis, determining at first phenomena of intoxication, then collapsus. Like the former, too, it modifies locally the circulation. So, then, certain substances penetrate, by the circulation, to the nerve-centres, and fix themselves there; as for alcohol, this fact is undeniable, and by direct researches on animals, and even on man, I have determined the presence of alcohol in the brain tissue itself. Other medicinal substances also localize themselves in the brain, and I cannot furnish you a better example than lead; in fact, saturnine encephalopathy is produced by the presence of this metal in the cerebral tissue, as has been proven by chemical analysis. Heckel has even shown that in animals submitted to lead-poisoning, this element, in fixing itself in the cerebral substance, alters the color of it.

So it is now known that certain medicaments, which produce modifications in the functions of the cerebro-spinal axis, act directly on the nerve-cells, and by their presence determine transient or permanent results, which modify the property of those cells; here, then, is a first fact which seems to be sufficiently established.

I must add that it is essential that the nervous ele-

[1] The respiratory centre in the medulla oblongata possesses a considerable resistance to the action of chloroform, but it is paralyzed in part, as the following experiment, performed by Vulpian, shows: In an animal not chloroformed, in which the pneumogastric nerve has been cut, if you electrize the central end of the nerve you determine complete arrest of the respiration; this lasts half or three-quarters of a minute. If you continue the electrization, the respiration resumes its course, and in order to obtain a new arrest of the respiratory movements, you must suspend for a time the electrization, to return to it again. In an animal plunged in the sleep of anæsthesia, electrization of the central end of the pneumogastric arrests respiration more readily than in the first case, and after this suspension the respiratory movements do not, of their own accord, come back again, and the animal, abandoned to itself, dies of respiratory syncope. This shows that the rachidian bulb is not in its normal state, and that the respiratory centre is weakened.—*Vide* Dictionnaire de Thérapeutique, D. Beaumetz, 1882, page 237. TRANS.

ments be intact, and this is a point to which I desire to call your attention, for it is of capital importance from a therapeutic point of view. We know, in fact, that under the influence of modifications, such as are determined by alcohol or by cerebral derangements, patients acquire a certain immunity from the therapeutic, and even from the toxic action of a great number of medicaments. We can, for instance, give to alcoholic patients, when affected with delirium tremens, or to maniacal patients, immense doses of morphia, atropia, or digitalis, without producing any symptoms of poisoning, although the same doses, in the same individuals, when in health, would speedily produce dangerous, if not fatal, symptoms.[1]

How shall we explain these facts? We can give a physiological explanation, based on a curious experiment of Claude Bernard and Paul Thernard. They etherized hares, then injected anhydrous prussic acid under the skin. Whenever the animal was plunged in the anæsthetic sleep, they could give him quite large doses of prussic acid without producing poisoning, but toxic symptoms appeared as soon as the animal recovered consciousness and sensibility.

This experiment is fundamental, and brings out with great clearness the capital fact, that when a nervous element is influenced or modified by a medicinal agent previously taken, it cannot be easily impressed by any other medicament. This explains the variable susceptibility to medicinal agents which some persons manifest—the tolerance of the nerve-cells for one modifier of function when influenced by another—the cases of mania above referred to, also those of alcoholic poisoning, where morphia in very large doses is borne with impunity. But as the action of the cerebro-spinal axis is in relation with the activity—greater or less—of the circulation, it is apparent that it is quite possible to modify the functions of the nervous system by modifying the circulation through the agency of medicinal substances. This it is that leads me to speak of the action of medicines on the vaso-motors.

Since the discovery of Pourfour du Petit, since more especially the curious experimentation of Claude Bernard, we know that the capillary circulation is dependent on the nervous system. This discovery immediately threw light on the actions of a great number of medicaments, and an attempt was made to divide them into two distinct groups, the one consisting of medicines that act on the vaso-dilators, the other of such as act on the vaso-constrictors.[2]

In the first group (of the vaso-dilators) were placed curare, opium and its alkaloids, eserine, and nitrite of amyl. In the second (or group of the vaso-constrictors)[3] a place was assigned to strychnia, ergot, belladonna, atropia, and the greater part of the poisons of the heart.

Unfortunately it must be admitted that this division is based rather on hypothesis than on any rigorous scientific demonstration of their action; and in order to show you how difficult is the subject, I will take from the two groups two substances, and will tell you what we know that is positive concerning their vaso-motor action. As representing vaso-constrictive medicaments, I will take ergot; as a vaso-dilator medicament, I will take morphia.

It was in 1849 that a Belgian physiologist, Savet, affirmed for the first time that ergot of rye, whose ecbolic action was well known, caused the arteries to contract. John Simon, in England, in 1850, taught the same doctrine, and both maintained that this constrictive action on the arteries was concerned in all the pharmaceutical and toxic properties of the drug.[1] But before these statements could be accepted as fact, they must be demonstrated by experiment, and Holmes, Wernich, Schuller, Vogt, showed in frogs, as well as in higher animals, cats and hares, the constrictive action on the arteries of these animals of ergot of rye and of ergotine.

But how is this action on the unstriped muscle of these arteries effected? Is it a direct effect, or is it brought about by an influence on the constrictor nerves? Here experiments are contradictory. Wernich and Schuller affirm that the contraction takes place when the vessel is deprived of all the nerves which it receives from the great sympathetic; Vogt, on the contrary, affirms that the vaso-constrictive action of ergot results from modifications wrought in the vaso-motor centres. As you perceive, physiology has not given a clear answer to the question, and, as Vulpian well says, we

[1] According to Vulpian, medicines which act on the vaso-motors are divisible into two groups, as given in the text (*vide supra*). These vaso-motor effects may be produced in various ways. Toxic substances may act on the unstriped muscular fibres directly, or primarily on the nerves, or vaso-motor nerve-centres. By direct examination, the effect of medicinal substances on the circulation has been studied, *i. e.*, by the sight, by the hæmadynamometer, and by the sphygmograph (Bordier's method); then by successive destruction of the vaso-motor nerve filaments, or vaso-motor centres, it has been attempted to limit the action of the substance under experimentation. Nevertheless, despite all the scientific rigor brought into these investigations, only confused and uncertain results have been obtained.—Vulpian, "Leçons sur l'Appareil Vaso-moteur," tome xii. p. 724, 1875. (*Vide* Bordier, Schaller, De Bernel de Pontives, etc.)

[2] I have seen teaspoonful doses of tincture of digitalis given in delirium tremens and in mania without any very perceptible effect. There is the same tolerance of chloral. I have given as much as three drachms (℥iij) in one night to a patient in delirium tremens, without producing any profound sleep; have seen five grains of morphia by mouth prove futile.—TRANS.

[3] In frogs poisoned by nicotine, Claude Bernard has seen arrest of the circulation in the interdigital membrane, and contraction of the arterioles. Hence he affirmed that nicotine has a vaso-constrictive action. In Vulpian's opinion, this arrest of the circulation is due to disturbance of the functions of the heart. It has been asserted that in animals poisoned by this drug ("nicotinized") the intra-arterial blood pressure is raised. Vulpian maintains, on the contrary, that if you will take the precaution to prevent all convulsive action by curarizing the animal, you will always find the blood pressure lowered, and there will be a marked congestion of the digestive tube, and especially the stomach. Sever the pneumogastrics in the neck, and there is no longer fall of the blood pressure. Heidenhain has shown that nicotine prevents the secretion of the submaxillary gland, without acting on the vaso-motors. From all this, it appears difficult to affirm that nicotine acts specially either on the vaso-motors or muscular fibres, and its action seems to be more complex than has been supposed.—Claude Bernard, "Leçons sur les Substance Toxiqués et Médicamentaires," 1857, p. 402, *et seq.* Heidenhain, Pflüger's Arch., t. v. p. 40–45. Vulpian, *loc. cit.*

[1] Savet, of Belgium, in 1849, and Simon, in 1850, first expressed the opinion that ergot causes the arterioles to contract. Savet attributed to contraction of the arteries all the phenomena which ergot determines (contraction of the uterus, of the bladder, etc.). Simon, on the other hand, affirmed a specific direct action on the unstriped muscular fibre everywhere. Holmes (Thèse de Paris, 1870), has studied experimentally the action of the ergot on the circulation. Injecting ergotine into the tongues of frogs, he has noted arterial constriction lasting twenty-five to thirty-five minutes. This effect was also noticed in the interdigital membrane after section of the sciatic nerve. He concludes that ergot has a direct action on the muscular fibres of the arterial walls.

Wernich, in experiments on hares and cats, has seen certain arterioles of the ear and pia mater contract, and this contraction take place even after section of the sympathetic, which innervates these vessels. Schuller has obtained the same effect in the vessels of the pia mater, after section of the cervical sympathetic.

Vogt, on the other hand, affirms that the active principles of ergot of rye act on the vaso-motor centres.

Vulpian is of opinion that these experiments are not demonstrative, and that the direct action of ergot on the smooth muscular fibre has not yet been substantiated.—Holmes (*loc. cit.*), Vulpian (*loc. cit.*), Wernich (*Virchow's Arch.*, 1872, t. 56, p. 19), Schuller (*Centralblatt*, 1871, No. 51), Vogt (*Berlin. klin. Wochenschrift*, 1872, No. 10), Labadie Lagrave, L'Ergot de Seigle en France, et en Angleterre (*Gaz. Hebdom.*, 1873, p. 249).

have as yet no decisive test-experiment on either side.

We find the same difficulty, *àpropos*, of the study of morphia. Doubtless, morphia brings about a congestion of the face, causes constriction of the pupil, and seems to produce a relaxation of the unstriped muscular fibres. But how is this action effected? This is a problem not yet solved.

Whatever may be the *modus operandi*, one may nevertheless say, taking his stand on data already acquired, that the group of spasmodic and anti-spasmodic medicaments owes its therapeutic action solely to the effect which these substances produce on the smooth muscular fibres, and that this effect is more likely indirect, being primarily exerted on the vaso-motors. It is, in fact, very difficult to affirm, with all the care that one may take in conducting the experiment, that one has destroyed all the nervous elements which innervate a group of muscles, or the walls of a bloodvessel. Moreover, in sectioning the nerves, the terminal extremities of the nerves still exist, and it is probable, I affirm, that it is by acting on these extremities that the contraction or relaxation of the muscular elements is produced.

But this is not all; medicaments act also on the secretions, and we must recognize the fact that this is one of the most important results that we look for in the administration of remedies; whether it be the kidneys, the salivary glands, or the skin with which we are concerned, we acknowledge the remedial efficacy, in morbid conditions of these organs, of diuretics, sialagogues, and sudorifics.

Till quite recently, it was supposed that certain principles contained in these medicaments, by a direct action on the glandular element itself, promote secretion; to-day, since the discovery of secretory nerves, this theory ought to be abandoned, and the admission made that these medicines act either directly on those nerves, or on the membrane of unification which binds them to the secretory elements.

But in order to show you, gentlemen, on what experimental data is based this new method of regarding secretory medicaments, I shall finish this lecture by briefly reviewing the curious experiments which have been made *àpropos* of the action of jaborandi and atropine in certain salivary glands.

Among these glands is one which lends itself readily to experiment, as far as the nerves which innervate it are concerned—the submaxillary. This gland receives two sets of nerves; one set comes from the lingual branch of the inferior maxillary, and from the chorda tympani; another set comes from the superior cervical ganglion. By destroying the latter, or cutting the former, one may study the influence of these two sets of nerves—whose origin is so different—on the secretion of this gland, for a tube introduced into Wharton's duct enables you justly to estimate the flow of saliva in the curarized animal.

When the chorda tympani is irritated, the circulation in the gland and the glandular secretion are augmented.[1] Heidenhain was the first to show that when an animal is poisoned by atropine, irritation of the chorda tympani produces augmentation of the circulation, but does not provoke the secretion of saliva; the atropine then has acted on the secretory nerves, but it has respected the vaso-motors. And if any one should say that the atropine has directed and limited its action to the secreting cell, whose effect it has destroyed, the reply is that we can restore the secretion of saliva by exciting the branch of the great sympathetic, which fact proves that the glandular parenchyma is not altered in its functions.

In another animal submitted to similar experimentation, but treated by subcutaneous injections of pilocarpine, instead of atropine, an increase in the secretion of saliva was noted. When, moreover, both these alkaloids were introduced, the one after the other, in the same animal, the phenomenon of exaggerated secretion was no longer seen, these two substances being in therapeutic antagonism. What does this experimentation show? It is this—that jaborandi does not determine the salivary secretion, as Gubler thought, by the presence of certain of its principles in the secreting cell itself, for we have seen by the first experiment that atropine does not destroy the properties of the cells, but that there is a special action on certain elements, which it remains for us to designate. What is the anatomical element on which atropine, on which jaborandi acts? Is it the nervous element itself? First of all, we must exclude all action on the nerve-centres or nerve-tubes. We have seen the action of atropine and jaborandi manifested in animals in which had been extirpated both the chorda tympani and the nerves from which it is derived, and the ganglia of the sympathetic; the effect then of these two medicaments must be exerted, if at all, on the peripheral portion of these nerves. But between the extremities of the terminal filaments of the branches of the sympathetic and those of the chorda tympani, from an anatomical point of view, no difference exists, and it is difficult to admit that a medicinal or toxic substance, introduced by the circulation, can leave intact the structure of one set of fibres, while altering the structure of the other.

It is probable, then, that it is not on the extremities of the nerve-fibres[1] that such toxic substances as jaborandi and atropine act, but rather on the "unifying substance," which is interposed between the nerve terminations of the chorda tympani, or sympathetic, on the one hand, and the secreting elements on the other.

What is this "unifying substance?" Here is a great anatomical and physiological problem which is not yet solved, and it is for the future to define it, and to assign to it its part in the process of secretion.

But I ought to assure you, that if the difficulties of these physiological problems augment in proportion as experimental analysis becomes more rigorous, it is none the less true that such researches give scientific

[1] When, after cutting the chorda tympani, you excite the peripheral end of that nerve, all the bloodvessels are seen to dilate, and the salivary secretion augments. Nevertheless, these two effects, the vaso-motor and the secretory, are distinct, for woorari, given in a certain dose, paralyzes the secretory action, without at all modifying the vaso-motor action. The same result is obtained with atropine or cicutine. The experiments of Vulpian, of Heidenhain, and of Joliet, are, in this respect, absolutely demonstrative. There are, then, medicaments which act on the nerves of secretion, without acting on the vaso-constrictors, or vaso-dilators. —Vulpian, "Leçons sur les Substances Toxiques et Médicamenteuses."

[1] Coyne has studied the terminations of the nerves in glands. He has found, under the limiting membrane of the parenchyma, triangular or elongated cells, with multiple prolongations, having all the characters of nerve cells. He has been able to follow the nerve fibres through to the cells, but has not succeeded in finding the connecting substance which binds the cells to the epithelial elements. Pflüger has described very fine nervous filaments terminating in the epithelium itself, but he is the only one who has yet traced these terminations in the epithelium of glands. Rouget disputes Pflüger's assertion that the fibres discovered by him were nervous filaments, for they keep their sheath of myeline to their termination in the gland substance—an exception to the rule.

Hermann, in observations of sweat glands, has seen fine nerve filaments in the limiting membrane of the glands. Caidiat explains the presence of these nerve filaments in this situation by the fact of the existence of a great number of muscular fibres in the parietes of the glands; he thinks that Hermann's nerve filaments are destined to innervate these muscular elements.—Coyne, "De la terminaison des nerfs dans les glandes," (Comptes Rendus de l'Académié des Sciences, 1878). Cardiat, "Traité d'Anatomie Générale," t. ii. p. 153.

precision to the study of the actions of medicines, and that it is in this way only that experimental therapeutics can progress.

Such are the general considerations that I desired to present to you relative to the nervous system considered from a therapeutic standpoint; they show you the difficulties of the problem and how these researches should be conducted in the future.

ORIGINAL ARTICLES.

NOTES ON THE MANAGEMENT OF RINGWORM OF THE SCALP (TINEA TONSURANS).

BY ARTHUR VAN HARLINGEN, M.D.,

CHIEF OF THE SKIN CLINIC, HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

I HAVE called the following remarks notes on the *management* of ringworm of the scalp, because they deal rather with the application of the remedies used than with the treatment of the disease in the ordinary acceptation of the term.

There is no lack of good and efficient remedies for tinea tonsurans, and the chief reason for disappointment and failure in the use of these remedies lies, I think, in their unintelligent application.

It must be kept in mind that in ringworm of the scalp we have to deal with a subtile and penetrating fungus, which invades the follicles to their lowest recesses, grows with persistent luxuriance, and refuses to yield to any remedy, no matter how active it may be, which is not brought into intimate contact with every minute germ. It is perfectly useless to give the patient a parasiticide lotion or ointment with a vague, general direction to rub it on or into the diseased patches of skin. Though such an application may kill the fungus as it exists on the surface, it can not touch the germs which have penetrated the follicles, and there remain intact and ready to spring into new life as soon as the parasiticide is withdrawn.

To understand the difficulties which must be overcome in order that the parasiticide may be brought into contact with the fungus, it must be remembered that the hair-follicles of the scalp, while they are often as much as ⅜ of an inch in length, are only about $\frac{1}{50}$ of an inch in diameter; in other words, they are little wells nearly twenty times deeper than they are wide. When it is considered that the greater part of this narrow calibre is usually filled by the growing hair-shaft, the attempt to cure an old case of ringworm of the scalp, when the fungus has penetrated to the very bottom of the follicle, by smearing an ointment, or swabbing a wash over the surface, is seen at once to be a vain effort.

Depilation indeed is usually the first proceeding to which attention must be paid in the management of ringworm of the scalp; not the indiscriminate pulling out of all hairs in the neighborhood of the diseased patch, but the extraction of those only which appear to the naked eye, or to the eye aided by a small lens, to be diseased.

The difference in appearance between a healthy hair and one which has been attacked by the ringworm fungus, may usually be easily recognized by the naked eye. In the first place the diseased hair is broken off short with a length of ⅛ to ¼ of an inch. The spores by their multiplication have separated its fibres, and the texture of the hair has been rendered brittle. The broken end is split so as to look like one of those old-fashioned birchen brooms which are used to sweep the streets. The hair-stump itself is enlarged to three or four times the diameter of the healthy hair, and its lustre is diminished, so that it can be singled out from a group of hairs cut to the same length. The color also is usually lighter, and it has a dry lifeless look.

Depilation should be practised systematically, a certain limited area being selected for each operation, and not a few hairs plucked here and there over a large surface. Immediately after depilation the parasiticide is to be applied with the hope of penetrating the still yawning follicles from which the hairs have just been removed.

It must be remembered that, not only does the fungus penetrate the follicles in which it has been lodged, but it tends to spread by being carried about from one part to another of the head in brushing, rubbing, or scratching the scalp, etc. For this reason it is apt to be found at various points, and in examining the scalp in a case where a single characteristic patch has been found care should be taken to go over the whole head with a view of learning whether some incipient and superficial patches may not be found, the timely application to which of a parasiticide may nip the disease in the bud. The patient's head should be firmly held while the hair is turned back in successive rows from front to back, or *vice versa*, so that no points shall remain unexamined. Every diseased patch should of course be made the subject of active treatment, but some parasiticide should also be kept in contact with all parts of the scalp, in order that the floating fungus may have no opportunity to light upon any unprotected spot.

It is too often supposed that treatment need be applied only to the characteristic ashen-gray, slightly raised patches with their goose-flesh-like arrangement of broken stumps, which go to make up the typical picture of ringworm of the scalp. But, as has been pointed out, the fungus is so insidious that it must be looked for, not only here, but in all parts of the scalp, where its presence may be indicated by a few scales like a small round patch of dandruff, with perhaps a single stump of a diseased hair, or even one or two of those black dots in the scalp, which are the stumps broken off even with the surface, and which form the most troublesome points to reach with parasiticides. Now and then an isolated diseased stump may be found among the healthy hairs, and this, unless looked after, may become a focus of disease.

One of the mistakes sometimes made in the management of ringworm is that of having the scalp washed too often. The parasiticide, whatever its nature, should be left undisturbed on the surface. The longer it remains in contact with the skin, the more it is likely to penetrate to the points where its influence is most needed. Once in two weeks is often enough to wash the scalp in an average case.

In order that the remedies may be properly ap-

plied, the hair must be shaved or at least cut very short. My own custom is to direct that the head be kept closely shaved for a week or so, the remedies being applied regularly during that time, and that the hair be then permitted to grow for a day or two, in order to take an account of progress, and to see what proportion of diseased hairs still remain. Of course, the limited locality where depilation is being practised at any given time must be left unshaven, so that the hairs may grow long enough to permit of their being readily plucked.

It is generally best to apply remedies with a mop or sponge tied to the end of a stick, because the end of the finger is scarcely firm enough to be of service. The scalp, it must be remembered, is not as sensitive as other portions of the body, and will bear with impunity an amount of rough handling which would prove injurious elsewhere. Ointments as well as washes may be applied thus with advantage. I am accustomed to use mops made of old-fashioned candle-wick tied to the end of a stick the size of a crow-quill and five inches in length. These are made for me in quantity, and as they cost next to nothing may be thrown away as used.

Of course the scalp must not be made sore; when this occurs treatment must be suspended and valuable time is lost. There is a great difference in different individuals as to the sensitiveness of the scalp. An application which will agree with one child, and which may be rubbed in most vigorously with entire impunity, will in another by its mere application in the gentlest manner give rise to violent inflammation. In some individuals the scalp is so sensitive, especially when the ringworm has lasted some time and has been much treated, that none but the mildest remedies can be tolerated. It is always well to begin a little cautiously in severe cases or those of long standing, and it is never safe to send a patient away for some days or weeks with a new remedy, the effect of which in the case has never been tested.

(To be concluded.)

PHOTO-MICROGRAPHY BY ORDINARY LAMP-LIGHT.

BY GEORGE A. PIERSOL, M.D.,
OF PHILADELPHIA.

WITH the ever-increasing devotion to microscopical research, the need of ready and accurate means of reproducing what is seen in the instrument is becoming more and more imperative; while for elementary demonstration, or for the illustration of text-books the semi-diagramatic drawings are, probably, to be preferred; yet for original research regarding matters where differences of opinion and interpretation are likely to arise, some method less open to the charge of inaccuracy, from lack of artistic ability, or from a pencil influenced by preconceived ideas, is eminently desirable. To the more or less perfect fulfilment of these requirements photo-micrography has always laid claim.

Regarding the capabilities of photography in this connection nothing need be said, as all are familiar with the beautiful productions of the Army Medical Museum, from the hands of Dr. J. J. Woodward. It is, however, with a view of directing attention to the simplicity and readiness with which photography may be utilized that the present notes are offered.

The introduction and perfecting during the last few years of "dry" plates has greatly simplified what, during the "wet" collodion process, was more or less complicated work, requiring, for the best results, a considerable outlay for apparatus.

Formerly, when the "wet" plates were the only ones employed, some source of powerful illumination, as sun, calcium, magnesium, or electric light, was necessary. Sunlight, probably, is the best illumination for photo-micrography; but to be used with convenience and the best results a heliostat is almost indispensable, together with a suitable southern exposure, and leisure during the busiest hours of the day—necessities which surrounded photo-micrography with obstacles which but the few especially interested cared to overcome.

The introduction of "dry" plates has opened the way for convenient and efficient methods which before were impossible. As is well-known, the "dry" plates are much more rapid and sensitive than the older "wet" ones, being readily impressed by any illumination of ordinary brilliancy, even the ordinary kerosene lamp of the microscopist's table. While the applicability and efficiency of such illumination is becoming well-known, comparatively few seem to have availed themselves of it, notwithstanding the readiness of its application.

Believing that a concise description of the method employed with very satisfactory results may aid those desiring to experiment in this direction, a few hints as to the apparatus and manipulations employed are given, which may be modified to meet individual wants.

The first care in arranging for photo-micrography is a firm and convenient table or base; this is best a well-seasoned board, some six or eight feet long, and from fourteen to sixteen inches wide. This is securely fastened to some support, which may with advantage be a firm table of ordinary size; the board, however, should be raised to a convenient height to avoid uncomfortable stooping while working. About eighteen inches from one end of the base is a convenient position for the microscope, the tube of which should be placed perfectly horizontal, care being taken that a good balance be maintained. The eye-piece of the instrument is best removed.

Owing to the great sensitiveness of the "dry" plates to any white light, it will, ordinarily, be found much more convenient to employ a camera, which must be so adjusted as to be at a proper height and at right angles to the axis of the microscope. As the amplification desirable will probably require the image to be received at some distance from the instrument (from thirty to forty-eight inches), an "extension" between the camera and tube of the microscope is necessary, which can readily be made from a cone of card-board or tin, with the precaution that all joints are light-proof. The tube of the microscope, as well as the extension, should be lined with dead-black paper.

The position of the focusing adjustments is thus removed beyond reach when the operator is closely
